INTRODUCTORY

THE material in this book can be absolutely relied upon. In using it, the student may be sure that he is dealing with master minds, each of whom has made a specialty of the science of which he treats. The editor has kept steadily in view the duty of a compiler. He has refrained from making digests, compends, or summaries of the works reviewed. He has not undertaken to advance any opinion, theory, or creed, but simply to give the fairest possible picture of the present state of science consistent with the primary purpose of the work as a volume of illustrations. Where eminent men differ in opinion, conflicting views have been allowed expression, leaving the name and authority of each author to answer for his own statements. The recording of a scientific opinion is not its advocacy, and that even leaders in science may well change their views with advancing knowledge is abundantly shown in the selections given, and freely admitted by the foremost among them.

In obedience to the primary and controlling purpose of scientific illustration, whatever in science can throw a "side-light" upon some intellectual, moral, political, industrial, social, or religious truth has been seized wherever found. The titles and location of topics are thus not what would be found in a scientific hand-book, which would place all matter treating of glaciers under *glacier*, of oxygen under *oxygen*, of volcanoes under *volcano*, etc. It is not primarily for the astronomical, geological, chemical, or other scientific teachings that the selections have been made, but for some truth relating to humanity, which they illustrate.

At the same time, it is believed that the selections will be found of exceeding interest for their own sake, and that they will open to many readers vistas of the wide reach of science, such as their special studies have not previously brought to their view. The minister, the teacher, or the busy worker in any profession, even if he devotes his spare time to science, can scarcely hope for extensive knowledge in more than some one of its many departments. Through these pages flashes of light will come to him from all, and he will thus gain a fuller view of the grand unity toward which all are tending.

Of the use of scientific illustrations in speaking or writing, it may be said that they are in harmony with the spirit of the age, which is preeminently scientific; that they have not the hackneyed character of the numerous popular anecdotes or of the stock illustrations long current in classic literature, and that they especially impress the thoughtful mind, as dealing with facts. However theories may change, the movements of suns and planets, the combinations of chemistry, the fossils and strata of geology, the properties of heat, light, and sound, the marvels of electricity, and the infinitesimal world of the microscope are facts, ascertained and demonstrable. The mind is there upon sure ground, and the use of such facts in illustration gives a sense of certainty and reality to the thoughts they are employed to illustrate.

The selections here given are not from works on so-called "popular science," where the element of popularity often quite swamps the scientific, where uncertified facts are given on the testimony of anonymous witnesses, and where the suspicion is often inevitable that the occurrence happened for the sake of the illustration. This work is based upon the belief that the essentials of science are simple enough for the untrained mind, and that whatever of abstruseness it contains is in processes or in their necessary technical terms, and that there are none who can state the essentials more clearly than those who know them most thoroughly at first hand—the leading specialists in the

various departments. An examination of the Index of Authors will show how high is the standing of the writers from whom the quotations are made, and a study of the selections will show how simple and lucid are their expositions of scientific truth. The reader cannot fail to be impressed also with the exceeding felicity of language, the beautiful descriptions of natural scenery, the sympathy with all the grandeur and beauty of Nature, and the wide outreach of thought and aspiration with which these extracts abound.

For each selection a number of topics for illustrative use are commonly suggested in the headlines, while still others are indicated in the various indexes; but so multiform are the relations of scientific truth to all other truth, that the thoughtful reader will constantly perceive new uses and adaptations of the same scientific fact. This suggestiveness of these extracts, reaching beyond anything that can be specified in set phrases, will be found among the most valuable qualities of this collection. While each selection is complete in itself and ready for immediate use, without reference to any other work, it will be found also of value as a guide to the sources from which other material of interest and value may be obtained; for these extracts, tho most carefully made, are yet but specimens of the riches to be found in the various works from which they are taken. The student will almost certainly find himself impelled to seek a fuller knowledge of some at least of the subjects presented in the volumes themselves of which these extracts form a part.

In the choice of authors to be quoted, the editor has been guided, not merely by his own opinion, but by the valued advice of eminent scholars, as Marcus Benjamin, A.M., Ph.D, F.C.S., Editor U. S. Nat. Museum, Washington, D. C.; Arthur Elmore Bostwick, Ph.D., New York Public Library, New York City; Professor Charles Sumner Dolley, M.D., Philadelphia, Pa.; Professor Albert Smith Bickmore, Ph.D., American Museum of Natural History, New York; Louis Pope Gratacap, Ph.B., American Museum of Natural History, New York; Professor Frank Hall Knowlton, Ph.D., U. S. Nat. Museum, Washington; Professor George Perkins Merrill, Ph.D., U. S. Nat. Museum, Washington, D. C.; Professor Theophil Mitchell Prudden, M.D., LL.D., Columbia University; Professor Frederick Starr, Ph.D., University of Chicago; Isaac Kauffman Funk, D.D., LL.D., Editor in Chief of Funk & Wagnalls STANDARD DICTIONARY, New York; Professor Edward Richard Shaw, Ph.D., New York University; Henry Newlin Stokes, Ph.D., U. S. Geol. Survey, Department of the Interior, Washington, D. C.; Professor Nathaniel Southgate Shaler, D.S., Harvard University—whose aid it is a pleasure here gratefully to acknowledge.

In the translation of extracts from foreign authors, Mrs. J. H. W. Stuckenberg, of Cambridge, Mass., has rendered admirable service.

A special debt of gratitude is due to authors who have granted the use of their copyright volumes or have furnished important monographs for quotation in this work, among whom should be particularly mentioned: the late John Fiske, LL.B.; Samuel Pierpont Langley, D.Sc., LL.D.; Professor William James, M.D., Ph. et. Litt.D., LL.D.; Professor Hugo Münsterberg, M.D., Ph.D.; Park Benjamin, Ph. D.; Otis Tufton Mason, Ph.D.; Israel C. Russell, M.S., LL.D.; Theodore Gill, M.D., Ph.D.; William James Beal, M.S., Ph.D.; William Keith Brooks, Ph.D., LL.D.; Clarence Moores Weed, Sc.D.; Henry Newlin Stokes, Ph.D.; Harvey W. Wiley, Ph.D., LL.D.; Hon. William Torrey Harris, Ph.D., LL.D., United States Commissioner of Education; and Leland Ossian Howard, Ph.D., Chief of the Division of Entomology, of the United States Department of Agriculture, who sent advance proofs of his valuable article on Smyrna Fig Culture in the United States.

The editor would also present his grateful acknowledgments to the publishers whose volumes of scientific facts and researches he has been privileged

to use, and whose courtesy and kindness it will always be a pleasure to remember: to D. Appleton & Co., of New York, whose International Library of Science and Modern Science Series have been of especial service and are to be commended as placing a great amount and variety of admirably selected material within the reach of the American or English reader in his own language; to the American Book Co., the Clarendon Press, the Columbia University Press, Wm. O. Allison, A. L. Burt, Dodd, Mead & Co., Doubleday, Page & Co., Fords, Howard & Hulbert, Harper & Brothers, Henry Holt & Co., the Humboldt Publishing Co., Longmans, Green & Co., James Pott & Co., G. P. Putnam's Sons, Charles Scribner's Sons, Sheldon & Co., John Wiley & Sons, and Wm. Wood & Co., of New York; to Ginn & Co., Houghton, Mifflin & Co, and Little, Brown & Co., of Boston; to the American Baptist Publication Society, the Henry Altemus Co., and J. B. Lippincott & Co., of Philadelphia; to the Schulte Publishing Co., of Chicago; to A. & C. Black, Bell & Sons, Chapman & Hall, J. M. Dent & Co., Harper & Brothers, Kegan Paul, Trench, Trübner & Co., Swan, Sonnenschein & Co., of London. Individual favors and courtesies more than can be here enumerated, but all of which are gratefully remembered, have aided in the preparation of the work.

JAMES C. FERNALD.

New York, December, 1902.

KEY TO ABBREVIATIONS

α—Alpha, designating a special star of group; thus, α (alpha) *Centauri* is the most brilliant star of the constellation Centaurus or Centaur. Other Greek letters are at times similarly used.
A.—D. Appleton & Co.
A. & S.—A. C. Armstrong & Son.
A.B.Co.—American Book Co.
A.B.P.S.—American Baptist Publication Society.
A. D. L. V.—Anleitung zur deutschen Landes und Volksforschung, Alfred Kirchof, editor.
Bell.—Bell & Sons.
Bl.—A. & C. Black.
Burt.—A. L. Burt.
C. & H.—Chapman & Hall.
Cl. P.—Clarendon Press.
C. U. P.—Columbia University Press.
D. & McC.—Doubleday & McClure Co.; Doubleday, Page & Company.
D. M. & Co.—Dodd, Mead & Co.
D. Z. S. F. Deutsche-Zeit und Streit-fragen.
F. H. & H.—Fords, Howard & Hulbert.

W. W.—William Wood & Co.

SCIENTIFIC SIDE-LIGHTS

1. ABERRATION OF LIGHT—*Apparent Motion of Stars in Space Due to Motion of the Earth.*—Bradley . . . noticed that the fixed stars did not really appear to be fixed, but that they describe little orbits in the heavens every year. The result perplexed him. . . . He was one day upon the Thames in a boat, and noticed that as long as his course remained unchanged, the vane upon his masthead showed the wind to be blowing constantly in the same direction, but that the wind appeared to vary with every change in the direction of his boat. "Here," as Whewell says, "was the image of his case. The boat was the earth, moving in its orbit, and the wind was the light of a star." . . . You will immediately understand the meaning of Bradley's discovery. Imagine yourself in a motionless railway-train, with a shower of rain descending vertically downwards. The moment the train begins to move the raindrops begin to slant, and the quicker the motion of the train the greater is the obliquity. In a precisely similar manner the rays from a star vertically overhead are caused to slant by the motion of the earth through space. Knowing the speed of the train, and the obliquity of the falling rain, the velocity of the drops may be calculated; and knowing the speed of the earth in her orbit, and the obliquity of the rays due to this cause, we can calculate just as easily the velocity of light.—TYNDALL *Lectures on Light*, lect. 1, p. 22. (A., 1898.)

2. ABRASION OF ROCKS BY GLACIERS—*Marks of Ice That Melted Ages Ago.*—In the first place, we have to consider the singular abrasion of the surfaces over which the glacier has moved, quite unlike that produced by the action of water. We have seen that such surfaces, wherever the glacier-marks have not been erased by some subsequent action, have several unfailing characteristics: they are highly polished, and they are also marked with scratches or fine *striæ*, with grooves and deeper furrows. Where best preserved, the smooth surfaces are shining; they have a luster like stone or marble artificially polished by the combined friction and pressure of some harder material than itself until all its inequalities have been completely leveled and its surface has become glossy. Any marble mantelpiece may serve as an example of this kind of glacier-worn surface.—AGASSIZ *Geological Sketches*, ser. ii, p. 34. (H. M. & Co., 1896.)

3. ——— *Rocks Are Cut by Existing Glaciers.*—At the lower end, and along the sides of many Alpine glaciers, the ice charged with sand and stones may be seen in direct contact with the smooth, polished, and striated rock surfaces. Below glaciers that have recently retreated, and where the surface is still bare of vegetation, records similar to those just mentioned may be observed in thousands of localities. The same is true, also, over vast regions that are known to have been formerly glaciated; while on adjacent areas, where the conditions are similar, excepting that they were not occupied by ice, the peculiar and not easily mistaken evidences of ice abrasion are lacking. We have, therefore, both positive and negative evidence pointing to the conclusion that glaciers abrade the rocks over which they flow.—RUSSELL *Glaciers of North America*, int., p. 19. (G. & Co., 1897.)

4. ABSENCE OF MIND—*Newton and the Egg.*—Always preoccupied with his profound researches, the great Newton showed in the ordinary affairs of life an absence of mind which has become proverbial. It is related that one day, wishing to find the number of seconds necessary for the boiling of an egg, he perceived, after waiting a minute, that he held the egg in his hand, and had placed his seconds watch (an instrument of great value on account of its mathematical precision) to boil!—FLAMMARION *Popular Astronomy*, bk. ii, ch. 1, p. 93. (A.)

5. ACCIDENT CONFIRMS SUPERSTITION—*Indian's Prognostication of Calamity—A Hunter's Omen.*—The effect of accidental occurrences upon an uneducated mind, in engendering superstition, is a subject which has often been dwelt upon, and the difficulty of eradicating the same—as may be judged of by the following accident which came under the observation of Mr. T. B.

Lloyd and the author, in 1873, when traveling in Newfoundland—will be easily appreciated. At the time to which I refer, my companion was bringing a canoe down the rapids below the Grand Pond in a country which is practically uninhabited, and where an Indian trapper would perhaps be the only person met with, and this not more than once a year. Whilst shooting the rapids one of the Indians, Reuben Soulian, shot at a deer passing up one bank of the river. That the deer had been hit was testified by a trail of blood which bespattered the rocks. Subsequently several more shots were fired, and it was believed by all that the deer was killed. Soulian quickly followed the animal to the spot where it was supposed to have fallen. Some time after he returned, having failed to find any trace of the animal. He was greatly agitated, but eventually became melancholy, saying that the sudden disappearance of the animal was a sure sign that some of his relations had suddenly died. About two hours afterwards Mr. Lloyd's party met with a party of Indians coming up the river, the first they had seen for four weeks, who told them that Soulian's sister had just died on the coast. —MILNE *Earthquakes*, ch. 18, p. 306. (A., 1899.)

6. ACCIDENT, HAPPY—*Measurement of Etna—Agreement of Masters.*—In 1815, Captain Smyth ascertained, trigonometrically, that the height of Etna was 10,874 feet. The Catanians, disappointed that their mountain had lost nearly 2,000 feet of the height assigned to it by Recupero, refused to acquiesce in the decision. Afterwards, in 1824, Sir J. Herschel, not being aware of Captain Smyth's conclusions, determined by careful barometrical measurement that the height was 10,872½ feet. This singular agreement of results so differently obtained was spoken of by Herschel as "a happy accident"; but Dr. Wollaston remarked that "it was one of those accidents which would not have happened to two fools."—LYELL *Principles of Geology*, ch. 25, p. 396. (A., 1854.)

7. ACCIDENT LEADS TO IMPORTANT INVENTION—*Electric Motor the Result of a Workman's Mistake.*—At an industrial exhibition in Vienna, in 1873, a number of Gramme machines were being placed in position, in order to exemplify the various uses to which the invention might be put as an electric generator, when there occurred one of those singularly fortunate accidents which have again and again played so prominent a part in the history of industrial progress. In making the electrical connections to one of these machines which had not as yet been belted to the engine-shaft, a careless workman attached to it by mistake a pair of wires which were already connected with another dynamo machine which was in rapid motion. To the amazement of this worthy artisan the second machine commenced to revolve with great rapidity in a reverse direction. Upon the attention of M. Gramme being directed to this phenomenon, he at once perceived that the second machine was performing the function of a motor, and that what was taking place was an actual transference of mechanical power through the medium of electricity. This singularly opportune occurrence, being commented upon in the scientific journals, led to the instant recognition of the true place of the electric motor in the domain of mechanics.—POPE, in *Electricity in Daily Life*, p. 46. (S., 1893.)

8. ACCIDENT LED TO THE DISCOVERY OF THE EARTH-CIRCUIT—The possibility of signaling without wires was in a manner forced upon him [Steinheil of Munich]. While he was engaged in establishing his beautiful system of telegraphy in Bavaria, Gauss, the celebrated German philosopher, and himself a telegraph inventor, suggested to him that the two rails of a railway might be utilized as telegraphic conductors. In July, 1838, Steinheil tried the experiment on the Nürnberg-Fürth railway, but was unable to obtain an insulation of the rails sufficiently good for the current to reach from one station to the other. The great conductibility with which he found that the earth was endowed led him to presume that it would be possible to employ it instead of the return wire or wires hitherto used. The trials that he made in order to prove the accuracy of this conclusion were followed by complete success; and he then introduced into electric telegraphy one of its greatest improvements—the earth-circuit.—FAHIE *Wireless Telegraphy*, p. 3. (D. M. & Co., 1900.)

9. ACCIDENT REENFORCES SUPERSTITION—*Profile Portrait Gives Offense to Savages—Artist Endangered.*—Catlin excited great commotion among the Sioux by drawing one of their chiefs in profile. "Why was half his face left out?" they asked; "Mahtocheega was never ashamed to look a white man in the face." Mahtocheega himself does not seem to have taken any offense, but Shonka, The Dog, took advantage of the idea to taunt him. "The Englishman knows," he said, "that you are but *half a man;* he has painted but one-half of your face, and knows that the rest is good for nothing." This view of the case led to a fight, in which poor Mahtocheega was shot; and as ill-luck would have it, the bullet by which he was killed tore away just that part of the face which had been omitted in the drawing. This was very unfortunate for Mr. Catlin, who had great difficulty in making his escape, and lived some months after in fear for his life; nor was the matter settled until both Shonka and his brother had been killed in revenge for the death of Mahtocheega.—AVEBURY *Prehistoric Times*, ch. 14, p. 505. (A., 1900.)

10. ACCIDENT, SEEMING, LEADS TO DISCOVERY OF URANUS—*Result of Sir William Herschel's Exhaustive Study.*—Altho Uranus was discovered by accident, it will not be thought that on that account small credit should be given to Sir W. Herschel, the astronomer, to whose redoubtable telescope this planet fell as a spoil. The accident was one which could not have happened but to an enthusiast in astronomical researches. He had penetrated into the star depths again and again with telescopes of his own construction, engaged in the attempt to solve problems of the utmost difficulty, when one night this new orb swept into his ken.—PROCTOR *Expanse of Heaven*, p. 115. (L. G. & Co.)

11. ACCIDENT UTILIZED BY MAN OF SCIENCE—*Darwin Led to the Study of Insectivorous Plants—Great Destruction of Insects by Drosera or Sundew.*—During the summer of 1860, I was surprised by finding how large a number of insects were caught by the leaves of the common sundew *(Drosera rotundifolia)* on a heath in Sussex. I had heard that insects were thus caught, but knew nothing further on the subject. I gathered by chance a dozen plants, bearing fifty-six fully expanded leaves, and on thirty-one of these dead insects or remnants of them adhered; and, no doubt, many more would have been caught afterwards by these same leaves, and still more by those as yet not expanded. On one plant all six leaves had caught their prey; and on several plants very many leaves had caught more than a single insect. On one large leaf I found the remains of thirteen distinct insects. Flies *(Diptera)* are captured much oftener than other insects. The largest kind which I have seen caught was a small butterfly *(Cœnonympha pamphilus)*; but the Rev. H. M. Wilkinson informs me that he found a large living dragon-fly with its body firmly held by two leaves. As this plant is extremely common in some districts, the number of insects thus annually slaughtered must be prodigious. Many plants cause the death of insects, for instance the sticky buds of the horse-chestnut, without thereby receiving, as far as we can perceive, any advantage; but it was soon evident that Drosera was excellently adapted for the special purpose of catching insects, so that the subject seemed well worthy of investigation.—DARWIN *Insectivorous Plants*, ch. 1, p. 1. (A., 1900.)

12. ACCIDENT YIELDS DISCOVERY TO TRAINED OBSERVER—*Goodyear First Vulcanized India-rubber by Chance.*—Goodyear, the sagacious and persevering investigator into the properties and uses of caoutchouc or india-rubber, had long inquired after some agent in nature which would remove from the substance in question its special sensibility to cold and heat, and make it in effect a new material. He discovered this long-desired agent in the most casual way. "In one of those animated conversations so habitual to him, in reference to his experiments, a piece of india-rubber combined with sulfur, which he held in his hand as the text of all his discourses, was by a violent gesture thrown into a burning stove near which he was standing. When taken out, after having been subjected to a high degree of heat, he saw—what it may be safely affirmed would have escaped the notice of all others—that a complete transformation had taken place, and that an entirely new product, since so felicitously termed 'new metal,' was the consequence." (Decision of the U. S. Commissioner of Patents.) . . . The eye of Goodyear was quickened by the watching and waiting of years to that sagacity which was able to see in the piece of refuse rubber casually discharged from the fire an answer to the question with which his mind had so long been burdened.—PORTER *Human Intellect*, pt. iii, ch. 8, p. 490. (S., 1899.)

13. ACCOMPLISHMENT OF THE IMPOSSIBLE—*Chemistry of Sun and Stars Revealed—Scientists' Predictions Falsified.*—Resuming in a sentence what has been already explained, we find that the prismatic analysis of the heavenly bodies was founded upon three classes of facts: First, the unmistakable character of the light given by each different kind of glowing vapor: secondly, the identity of the light absorbed with the light emitted by each; thirdly, the coincidences observed between rays missing from the solar spectrum and rays absorbed by various terrestrial substances. Thus, a realm of knowledge, pronounced by Morinus in the seventeenth century, and no less dogmatically by Auguste Comte in the nineteenth, hopelessly out of reach of the human intellect, was thrown freely open, and the chemistry of the sun and stars took its place among the foremost of the experimental sciences.—CLERKE *History of Astronomy*, pt. ii, ch. 1, p. 174. (Bl., 1893.)

14. ACCUMULATION OF ETHICAL FORCES—*Advance Must Be Unbroken.*—One must first learn, unmoved, looking neither to the right nor left, to walk firmly on the straight and narrow path, before one can begin "to make oneself over again." He who every day makes a fresh resolve is like one who, arriving at the edge of the ditch he is to leap, forever stops and returns for a fresh run. Without unbroken advance there is no such thing as accumulation of the ethical forces possible, and to make this possible, and to exercise us and habituate us in it, is the sovereign blessing of regular work.—BAHNSEN *Beiträge zur Characterologie*, quoted by JAMES in *Psychology*, vol. i, ch. 4, p. 124. (H. H. & Co., 1899.)

15. ACCUMULATION OF EXCITEMENTS—A stimulus which would be inadequate by itself to excite a nerve-center to effective discharge may, by acting with one

or more other stimuli (equally ineffectual by themselves alone) bring the discharge about. The natural way to consider this is as a summation of tensions which at last overcome a resistance. The first of them produce a "latent excitement," or a "heightened irritability"—the phrase is immaterial so far as practical consequences go; the last is the straw which breaks the camel's back.—JAMES *Psychology*, vol. i, ch. 3, p. 82. (H. H. & Co., 1899.)

16. ACCUMULATION OF SMALL IMPULSES — *Great Results.* — Extraordinary effects are produced by the accumulation of small impulses. Galileo set a heavy pendulum in motion by the well-timed puffs of his breath. Ellicot set one clock going by the ticks of another, even when the two clocks were separated by a wall. TYNDALL *Fragments of Science*, vol. i, ch. 22, p. 444. (A., 1900.)

17. ACCURACY OF ANCIENT BUILDERS—*Orientation of Great Pyramid—Exactness Not Attainable by Compass.*—It has been frequently maintained that the orientation of the great pyramid is such as to indicate, with reasonable probability, that the compass-needle was used in establishing the positions of its faces.

The difficulty with this supposition is that the pyramid is, in fact, placed with too great accuracy for the work to be done even by the best modern compass. Its sides face astronomically the north, south, east and west; not to the cardinal points of the compass, but to the azimuthal direction of the earth's axis and to a line at right angles thereto. The compass, however, is subject to variations, due to regular daily, monthly, yearly, and centennial changes in the earth's magnetic field, which controls it. Hence, the task of figuring backward the probable position of the needle at the time of the building of the pyramid—a period which is in doubt—might well cause despair in the most skilful investigator of terrestrial magnetism; for, in the least interval which has elapsed, the needle has probably swung over large angles from the true north, back and forth many times. But, granting such a possibility, still it may be safely questioned whether the most accomplished surveyor or topographical engineer of to-day could run the lines of the pyramid faces, by the aid of the best modern compass, with no greater error than 19′ 58″, which the French Academy, in 1799, determined to be the entire amount of variation of these faces from the true astronomical direction. —PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 3, p. 57. (J. W., 1898.)

18. ACCURACY OF DETAIL — *The Charm Alike of Science, Literature, and Art.*—In the sphere of natural investigation, as in poetry and painting, the delineation of that which appeals most strongly to the imagination, derives its collective interest from the vivid truthfulness with which the individual features are portrayed.—HUMBOLDT *Cosmos*, vol. i, int., p. 34. (H., 1897.)

19. ACCURACY OF MODERN ASTRONOMICAL INSTRUMENTS—*All the Light Gathered by a Two-foot Lens Concentrated on a Pin-point.*—The revolving dome above, the great tube beneath, its massive piers, and all its accessories are only means to carry and direct the great lens at the further end [of the equatorial telescope at Washington], which acts the part of the lens in our own eye, and forms the image of the thing to be looked at. Galileo's original lens was a single piece of glass, rather smaller than that of our common spectacles; but the lens here is composed of two pieces, each twenty-six inches in diameter, and collects as much light as a human eye would do if over two feet across. But this is useless if the lens is not shaped with such precision as to send every ray to its proper place at the eye-piece, nearly thirty-five feet away; and, in fact, the shape given its surface by the skilful hands of the Messrs. Clark, who made it, is so exquisitely exact that all the light of a star gathered by this great surface is packed at the distant focus into a circle very much smaller than that made by the dot on this *i*, and the same statement may be made of the great Lick glass, which is three feet in diameter—an accuracy we might call incredible were it not certain. It is with instruments of such accuracy that astronomy now works.—LANGLEY *The New Astronomy*, ch. 5, p. 122. (H. M. & Co.)

20. ACTION A CELESTIAL LAW—*Every Star in Motion.*—So far as observation has extended very few stars in the heavens have unchanging apparent positions. It is highly probable that in reality every star is in motion.—PROCTOR *Expanse of Heaven*, p. 282. (L. G. & Co., 1897.)

21. ACTION AND REACTION—*Increase of Magnetic Power—Progress of Scientific Discovery.*—The aspects of Nature provoke in man the spirit of inquiry. As the eye is formed to see, and the ear to hear, so the human mind is formed to explore and understand the basis and relationship of natural phenomena. A modern discovery illustrates the manner in which our present mastery over Nature has been obtained. We start with a magnet of infinitesimal power, which gives rise to electric currents of infinitesimal strength. These react upon the magnet, exalt its attractive and repulsive forces, thus enabling it to produce stronger currents, which again react upon and enhance the power of their source. Thus we rise from an origin too feeble to produce the slightest spark or gleam, to an energy competent to produce the solar brilliancy of the electric light. In a similarly small way the human mind began its operations among the powers of Nature, winning first a little

knowledge and a little strength, and then turning the knowledge and the strength so won back upon Nature, with the view of winning more. Action and reaction have thus gone on from prehistoric ages to the present time. The result is that stored body of scientific knowledge, and that developed power of scientific investigation, which have revolutionized philosophy, and begotten those marvels of practical science in the midst of which we dwell.—TYNDALL *Heat a Mode of Motion,* lect. 1, p. 1. (A., 1900.)

22. ACTION A NECESSITY TO CLENCH GOOD RESOLUTION—Seize the very first possible opportunity to act on every resolution you make, and on every emotional prompting you may experience in the direction of the habits you aspire to gain. It is not in the moment of their forming, but in the moment of their producing motor effects, that resolves and aspirations communicate the new "set" to the brain. No matter how full a reservoir of maxims one may possess, and no matter how good one's sentiments may be, if one have not taken advantage of every concrete opportunity to act, one's character may remain entirely unaffected for the better.—JAMES *Talks to Teachers,* ch. 8, p. 69. (H. H. & Co., 1900.)

23. ACTION, CONTINUOUS, OF EARTH-BUILDING FORCES—*Slow Upheaval and Subsidence of Lands Now Taking Place.*—Recent observations have disclosed to us the wonderful fact that not only the west coast of South America, but also other large areas, some of them several thousand miles in circumference, such as Scandinavia, and certain archipelagoes in the Pacific, are slowly and insensibly rising; while other regions, such as Greenland, and parts of the Pacific and Indian Oceans, in which atolls or circular coral islands abound, are as gradually sinking. That all the existing continents and submarine abysses may have originated in movements of this kind, continued throughout incalculable periods of time, is undeniable, and the denudation which the dry land appears everywhere to have suffered favors the idea that it was raised from the deep by a succession of upward movements, prolonged throughout indefinite periods. For the action of waves and currents on land slowly emerging from the deep affords the only power by which we can conceive so many deep valleys and wide spaces to have been denuded as those which are unquestionably the effects of running water.—LYELL *Principles of Geology,* ch. 11, p. 170. (A., 1854.)

24. ACTION IMPRESSES MEMORY—*Effort Better than Prompting.*—A curious peculiarity of our memory is that things are impressed better by active than by passive repetition. I mean that in learning by heart (for example), when we almost know the piece, it pays better to wait and recollect by an effort from within than to look at the book again. If we recover the words in the former way, we shall probably know them the next time; if in the latter way, we shall very likely need the book once more.—JAMES *Psychology,* vol. i, ch. 16, p. 686. (H. H. & Co., 1899.)

25. ACTION, INCALCULABLE, OF ELEMENTAL FORCES—*Freaks of Lightning.*—The house [struck by lightning at Montevideo] I saw shortly afterwards. . . . Some of the effects were curious. The paper, for nearly a foot on each side of the line where the bell-wires had run, was blackened. The metal had been fused, and altho the room was about fifteen feet high, the globules, dropping on the chairs and furniture, had drilled in them a chain of minute holes. A part of the wall was shattered as if by gunpowder, and the fragments had been blown off with force sufficient to dent the wall on the opposite side of the room. The frame of a looking-glass was blackened, and the gilding must have been volatilized, for a smelling-bottle, which stood on the chimney-piece, was coated with bright metallic particles, which adhered as firmly as if they had been enameled.—DARWIN *Naturalist's Voyage Around the World,* ch. 3. p. 62. (A., 1898.)

26. ACTION MAY BE REFLEX, NOT INDICATING MIND—If a man has his back broken in such a way as to sever the connection between his brain and lower extremities, on pinching or tickling his feet they are drawn suddenly away from the irritation, altho the man is quite unconscious of the adaptive movement of his muscles; the lower nerve-centers of the spinal cord are competent to bring about this movement of adaptive response without requiring to be directed by the brain. This non-mental operation of the lower nerve-centers in the production of apparently intentional movements is called reflex action, and the cases of its occurrence, even within the limits of our own organism, are literally numberless. Therefore, in view of such non-mental nervous adjustment, leading to movements which are only in appearance intentional, it clearly becomes a matter of great difficulty to say in the case of the lower animals whether any action which appears to indicate intelligent choice is not really action of the reflex kind.—ROMANES *Animal Intelligence,* int., p. 3. (A., 1899.)

27. ACTION OF ANIMALS—*Determined by Memory.*—The action of animals may be determined by memorial ideas, as well as by the corresponding sense-impressions. I often made the following amusing experiment with my own poodle. I had taught him to spring over a stick which I held out at the word "Jump!" One day I called the word out to him without presenting the stick. At first he looked at me in surprise, and then, as I repeated the command, barked impatiently. At last, after I had

given the order several times with a stern face, he decided to make a spring into the air, but barked loudly at me afterwards, as tho to complain of the absolute absurdity of my command. When I had repeated the experiment a number of times, the animal came to respond at once by springing into the air, but never failed to protest by growling and barking. The word of command aroused the memorial idea, and this was sufficient to arouse the action produced by the actual presentation of the stick; while the feeling of contrast between idea and object, and of the purposelessness of the act gave rise to unpleasurable emotions conflicting with the dog's habitual obedience.—WUNDT *Psychology*, lect. 24, p. 356. (Son. & Co., 1896.)

28. ACTION OF EXISTING CAUSES PROVED FOR THE PAST—*Lyell Transforms Geology.*—He completely refuted Cuvier's history of creation with its mythical revolutions, and established in its place the constant and slow transformation of the earth's crust by the continued action of forces, which are still working on the earth's surface, viz.: the movement of water and the volcanic fluid of the interior of earth. Lyell thus demonstrated a continuous and uninterrupted connection of the whole history of the earth, and he proved it so irrefutably, and established so convincingly the supremacy of the "existing causes," that is, of the causes which are still active in the transformation of the earth's crust, that geology in a short time completely renounced Cuvier's hypothesis.—HAECKEL *History of Creation*, vol. i, ch. 6, p. 132. (K. P. & Co., 1899.)

29. ACTION, RIGHT, TENDS TO RIGHT FEELING—*Forced Cheerfulness Will Conquer Depression.*—There is no more valuable precept in moral education than this, as all who have experience know: if we wish to conquer undesirable emotional tendencies in ourselves, we must assiduously, and in the first instance cold-bloodedly, go through the outward movements of those contrary dispositions which we prefer to cultivate. The reward of persistency will infallibly come, in the fading out of the sullenness or depression, and the advent of real cheerfulness and kindliness in their stead. Smooth the brow, brighten the eye, contract the dorsal rather than the ventral aspect of the frame, and speak in a major key, pass the genial compliment, and your heart must be frigid indeed if it do not gradually thaw! —JAMES *Psychology*, vol. ii, ch. 25, p. 463. (H. H. & Co., 1899.)

30. ACTIONS GOOD OR BAD IN THEMSELVES—*Harmony or Discord with Nature—Responsibility Dependent on Knowledge.*—Every act must have its own relation to the future. Every act must be either innocent, or beneficent, or hurtful in its ultimate tendencies and results. Or, if we like to put it in another form, every act must be according to the harmony of Nature or at variance with that harmony, and therefore an element of discord and disturbance. In all these senses, therefore, we speak, and we are right in speaking, of actions as in themselves good or bad, because we so speak of them according to our own knowledge of the relation in which they stand to those great axioms of morality, which are facts and not mere assumptions or even mere beliefs. But we are quite able to separate this judgment of the act from the judgment which can justly be applied to the individual agent. As regards him, the act is right or wrong, not according to our knowledge, but according to his own. And this great distinction is universally recognized in the language and (however unconsciously) in the thoughts of men. It is sanctioned, moreover, by supreme authority. The most solemn prayer ever uttered upon earth was a prayer for the forgiveness of an act of the most enormous wickedness, and the ground of the petition was specially declared to be that those who committed it "knew not what they did." —ARGYLL *Unity of Nature*, ch. 9, p. 198. (Burt.)

31. ACTIVITIES OF THE EARTH—*Like the Respiration and Movements of an Animal—Discovery of Causes a Part of Science.*—The internal heat of the earth, the elevation and depression of its crust, its belchings forth of vapors, ashes, and lava, are its activities, in as strict a sense, as are warmth and the movements and products of respiration the activities of an animal. The phenomena of the seasons, of the trade-winds, of the Gulf-stream, are as much the results of the reaction between these inner activities and outward forces, as are the building of the leaves in spring and their falling in autumn the effects of the interaction between the organization of a plant and the solar light and heat. And, as the study of the activities of the living being is called its physiology, so are these phenomena the subject-matter of an analogous telluric physiology, to which we sometimes give the name of meteorology, sometimes that of physical geography, sometimes that of geology. Again, the earth has a place in space and in time, and relations to other bodies in both these respects, which constitute its distribution. This subject is usually left to the astronomer; but a knowledge of its broad outlines seems to me to be an essential constituent of the stock of geological ideas. All that can be ascertained concerning the structure, succession of conditions, actions, and position in space of the earth, is the matter of fact of its natural history. But, as in biology, there remains the matter of reasoning from these facts to their causes, which is just as much science as the other, and indeed more.—HUXLEY *Lay Sermons*, serm. 11, p. 238. (G. P. P., 1899.)

32. ACTIVITIES UNDIFFERENTIATED IN ELEMENTARY ORGANISMS—*The*

Rhizopod or Ameba.—Where there are no distinctions of structure there are no distinctions of function. A rhizopod (*e. g.*, the ameba) will serve as an illustration. From the outside of this creature, which has not even a limiting membrane, there are protruded numerous processes. Originating from any point of the surface, each of these may contract again and disappear, or it may touch some fragment of nutriment which it draws with it, when contracting, into the general mass—thus serving as hand and mouth; or it may come in contact with its fellow-processes at a distance from the body and become confluent with them; or it may attach itself to an adjacent fixed object, and help by its contraction to draw the body into a new position. In brief, this speck of animated jelly is at once all stomach, all skin, all mouth, all limb, and doubtless, too, all lung.—SPENCER *Biology*, pt. ii, ch. 1, p. 200. (A., 1900.)

33. ACTIVITY OF MIND—*Increases Flow of Blood to Brain.*—The brain itself is an excessively vascular organ, a sponge full of blood, in fact; and [one] of Mosso's inventions showed that when less blood went to the arms, more went to the head. The subject to be observed lay on a delicately balanced table which could tip downward either at the head or at the foot if the weight of either end were increased. The moment emotional or intellectual activity began in the subject, down went the balance at the head-end, in consequence of the redistribution of blood in his system. But the best proof of the immediate afflux of blood to the brain during mental activity is due to Mosso's observations on three persons whose brain had been laid bare by lesion of the skull. By means of apparatus . . . this physiologist was enabled to let the brain-pulse record itself directly by a tracing. The intra-cranial blood-pressure rose immediately whenever the subject was spoken to, or when he began to think actively, as in solving a problem in mental arithmetic. Mosso gives in his work a large number of reproductions of tracings which show the instantaneity of the change of blood-supply, whenever the mental activity was quickened by any cause whatever, intellectual or emotional. He relates of his female subject that one day while tracing her brain-pulse he observed a sudden rise with no apparent outer or inner cause. She, however, confessed to him afterwards that at that moment she had caught sight of a skull on top of a piece of furniture in the room, and that this had given her a slight emotion.—JAMES *Psychology*, vol. i, ch. 3, p. 98. (H. H. & Co., 1899.)

34. ACTIVITY OF SOLAR FORCES—*Turmoil behind Beneficence—Productive Forces Not Always Beautiful in Operation.*—The furnace [the sun] whose fires maintain the life of the solar system is not merely aglow with intense light and heat, but is in a state of fierce turmoil. The most tremendous conflagrations ever witnessed upon our earth—great fires, by which whole cities have been destroyed—serve to suggest something of what is going on upon the sun, only that all the processes of such catastrophes must be supposed to be intensified a million-fold. As in great fires, there is a constant roar and tumult produced by the rush of air currents which the fire itself has generated, so in every part of the sun, on every square yard of that enormous surface, the most hideous uproar must prevail as fierce cyclonic storms, bred by solar fires, rush with inconceivable velocity over the flaming surface. In the most tremendous storms known upon earth the wind does not travel a hundred miles per hour, and the winds which rage amid the flames of a conflagration are of slow motion compared with true hurricanes; but the cyclonic storms which stir the fiery breath of the solar flames career often with the inconceivable velocity of more than a hundred miles in every second of time.—PROCTOR *Expanse of Heaven*, ch. 2, p. 17. (L. G. & Co., 1897.)

35. ACTIVITY OF SWALLOWS—*Usefulness as Insectivorous Birds.*—Swallows are eminently insectivorous. The tree-swallow is known to feed on bayberries when its usual fare is wanting, but, with this exception, it is doubtful if any but insect food passes a swallow's bill from one year's end to another. Recalling now the activity of swallows, which both necessitates a large supply of food and procures it, we must realize that these birds are incalculably beneficial.—CHAPMAN *Bird Life*, ch. 7, p. 212. (A., 1900.)

36. ACTIVITY, VOLCANIC, ON THE MOON—*Conflicting Testimony Explained.*—In the Sea of Nectar we see a small crater, of which the diameter measures about 6,000 meters (about 3¾ miles), rising isolated in the midst of a vast plain. Well, this crater is sometimes visible and sometimes invisible. From 1830 to 1837 it was certainly invisible, for two observers absolutely strangers to each other, Madler and Lohrmann, have minutely analyzed, described, and drawn this lunar country, and saw, very near the position it occupies, details of the ground very much less important than itself, without having the least suspicion [of it]. In 1842-43 Schmidt observed this same country without perceiving it. He saw it for the first time in 1851. It may be distinguished very well in a direct photograph by Rutherfurd taken in 1865. But in 1875 the English selenographer Neison examined, drew, and described this same place, with details the most minute and measures the most precise, without perceiving any trace of the volcano. Since then it has been seen again several times. It seems that the most simple explanation to give of these changes of visibility would be to admit that this volcano now and then emits smoke or vapors which remain for some time sus-

pended above it and hide it, as would happen to an aeronaut looking down from some height above Vesuvius at the epoch of its eruptions.—FLAMMARION *Popular Astronomy,* bk. ii, ch. 7, p. 152. (A.)

37. ACTOR PRACTISES ILLUSION ON AUDIENCE—*In Part upon Himself.*—Among all varieties of this deception [of self], that of the stage is the most complete. The actor is a man who has elaborately trained himself in the simulation of certain feelings. And when his acting is of the best quality, and the proper bodily attitude, gesture, tone of voice, and so on, are hit off, the force of the illusion completely masters us. For the moment we lose sight of the theatrical surroundings, and see the actor as really carried away by the passion which he so closely imitates. Histrionic illusion is as complete as any artistic variety can venture to be.—SULLY *Illusions,* ch. 9, p. 222. (A., 1897.)

38. ACTS, AUTOMATIC, ACCOMPLISHING A PURPOSE—*The Decapitated Frog—Organism Constituted to Secure Its Own Protection.*—It is well known that, if the hind-foot of a frog that has had its head cut off be pinched, it is withdrawn from the irritation. The stimulus to the afferent nerve reaches the gray matter of the spinal cord, and sets free a force which excites to action the corresponding motor nerves of the same side. When the foot is pinched more strongly, the force liberated by the stimulus passes across the cord to the motor nerves of the opposite side, and there is a simultaneous withdrawal of both limbs; and, if the excitation be stronger still, there is a wider irradiation of the effects of the stimulus in the gray matter, and a movement of all four limbs follows, the frog jumping away. These movements of the decapitated frog, which it is plain effect the definite purpose of getting it out of the way of harm, we believe to be analogous to the violent coughing by which food that has gone the wrong way is expelled from the human larynx, or to the vomiting by which offending matter is ejected from the stomach. Independently of consciousness and of will, an organism plainly has the power—call it intelligent or call it what we will—of feeling and eschewing what is hurtful to it, as well as of feeling and ensuing what is beneficial to it.—MAUDSLEY *Body and Mind,* lect. 1, p. 15. (A., 1898.)

39. ADAPTABILITY AMONG ANIMALS—*Horse and Ox Follow Man—Meet Man's Enemies in Every Clime.*—This spectacle [horses attacked by crocodiles] involuntarily reminds the contemplative observer of the adaptability granted by an all-provident nature to certain animals and plants. Like the farinaceous fruits of Ceres, the ox and horse have followed man over the whole surface of the earth—from the Ganges to the Rio de la Plata, and from the sea-coast of Africa to the mountainous plain of Antisana, which lies higher than the Peak of Teneriffe. In the one region the northern birch, in the other the date-palm, protects the wearied ox from the noonday sun. The same species of animal which contends in eastern Europe with bears and wolves is exposed, in a different latitude, to the attacks of tigers and crocodiles!—HUMBOLDT *Views of Nature,* p. 17. (Bell, 1896.)

40. ADAPTABILITY OF BIRDS—*Sparrows Utilize Electric Light.*—Some birds are influenced by changes in their surroundings, and alter their nesting habits when it proves to their advantage to do so. Chimney-swifts, who have exchanged hollow trees, in which they were exposed to their natural enemies, for the comparative safety of chimneys, are good examples. But a far better one is given by that prodigy in feathers, the house-sparrow. Is there any available site in which this thoroughly up-to-date bird will not place its nest? It has taken possession of even the hollow spaces about certain kinds of electric lamps, and has been observed repairing its nest at night by their light!—CHAPMAN *Bird Life,* ch. 5, p. 68. (A., 1900.)

41. ADAPTABILITY OF THE VERTEBRATE TYPE—*Laws of Nature the Expression of a Purpose.*—Among the many wonders of nature there is nothing more wonderful than this—the adaptability of the one vertebrate type to the infinite variety of life to which it serves as an organ and a home. Its basement has been so laid that every possible change or addition of superstructure could be built upon it. Creatures destined to live on the earth or in the earth, on the sea or in the sea, under every variety of condition of existence, have all been made after that one pattern; and each of them with as close an adaptation to special function as if the pattern had been designed for itself alone. It is true that there are particular parts of it which are of no use to particular animals. But there is no part of it which is not of indispensable use to some member of the group; and there is one supreme form in which all its elements receive their highest interpretation and fulfilment. It is indeed wonderful to think that the feeble and sprawling paddles on a newt, the ungainly flippers of a seal, and the long leathery wings of a bat, have all the same elements, bone for bone, with that human hand which is the supple instrument of man's contrivance, and is alive even to the finger-tips, with the power of expressing his intellect and his will. Here again the laws of nature are seen to be nothing but combinations of force with a view to purpose: combinations which indicate complete knowledge, not only of what is, but of what is to be, and which foresees the end from the beginning.—ARGYLL *Reign of Law,* ch. 4, p. 123. (Burt.)

42. ADAPTATION ADMITTED—*Design Denied—Appearance of Purpose Assumed*

to be without a Plan.—The struggle for life in natural selection acts with as much selective power as does the will of man in artificial selection. The latter, however, acts according to a plan and consciously, the former without a plan and unconsciously. This important difference between artificial and natural selection deserves especial consideration. For we learn by it to understand how arrangements serving a purpose can be produced by mechanical causes acting without an object, as well as by causes acting for an object. The products of natural selection are arranged even more for a purpose than the artificial products of man. and yet they owe their existence not to a creative power acting for a definite purpose, but to a mechanical relation acting unconsciously and without a plan.—HAECKEL *History of Creation*, vol. i, ch. 11, p. 284. (K. P. & Co., 1899.)

43. ADAPTATION CERTAINLY KNOWN—*The Only Question the Method of Its Production.*—And yet scientific men sometimes tell us that "we must be very cautious how we ascribe intention to nature. Things do fit into each other, no doubt, as if they were designed; but all we know about them is that these correspondences exist, and that they seem to be the result of physical laws of development and growth." Very likely: but how these correspondences have arisen, and are daily arising, is not the question, and it is immaterial how that question may be answered. Do those correspondences exist, or do they not? The perception of them by our mind is as much a fact as the sight or touch of the things in which they appear. They may have been produced by growth—they may have been the result of a process of development—but it is not the less the development of a mental purpose. It is the end subserved that we absolutely know. What alone is doubtful and obscure is precisely that which we are told is the only legitimate object of our research—viz.: the means by which that end has been attained.—ARGYLL *Reign of Law*, ch. 1, p. 20. (Burt.)

44. ADAPTATION, MUTUAL, OF DIVERSE ORGANISMS—*Dandelion Seed—Water-beetle.*—The structure of every organic being is related, in the most essential yet often hidden manner, to that of all the other organic beings with which it comes into competition for food or residence, or from which it has to escape, or on which it preys. This is obvious in the structure of the teeth and talons of the tiger; and in that of the legs and claws of the parasite which clings to the hair on the tiger's body. But in the beautifully plumed seed of the dandelion, and in the flattened and fringed legs of the water-beetle, the relation seems at first confined to the elements of air and water. Yet the advantage of the plumed seeds, no doubt, stands in the closest relation to the land being already thickly clothed with other plants, so that the seeds may be widely distributed and fall on unoccupied ground. In the water-beetle, the structure of its legs, so well adapted for diving, allows it to compete with other aquatic insects, to hunt for its own prey, and to escape serving as prey to other animals.—DARWIN *Origin of Species*, ch. 3, p. 71. (Burt.)

45. ADAPTATION OF COLOR TO ENVIRONMENT—*Black Cattle in Scotland—Trout Colored Like Bottom of Stream.*—The breeders of the polled Angus—a particular race of black cattle in Scotland—who make a great point of keeping up the perfect uniformity of their blackness, getting rid of every individual that has even a single white foot—take care to have everything black about their farmsteads; all the buildings are black, the horses are black, the dogs are black, the fowls are black. No breeder will have anything colored or white about his place. Tho no account can be given of the physiological action which makes these precautions effective (as they are asserted to be) in securing the desired result, yet I am strongly inclined to think that some influence of this kind is concerned in producing many singular correspondences between the surface-aspect of fishes and crustacea inhabiting shallow waters, and the characters of the bottoms on which they live. Every angler for trout is familiar with variations of this kind; and I have been assured of cases in which these fish, when transferred from one part of a stream to another, were found in no long time to have undergone a change in surface-markings, which gave them the same conformity to the new bottom as they previously had to the old.—CARPENTER *Nature and Man*, lect. 15, p. 443. (A., 1889.)

46. ——— ——— *Shades of Color Varied in Different Surroundings.*—To birds placed at so great a disadvantage, by a feeble flight and other adverse circumstances, in the race of life, bright colors would certainly prove fatal. It is true that brown is not in itself a protective color, and the clear, almost silky browns and bright chestnut tints in several species are certainly not protective: but these species are sufficiently protected in other ways, and can afford to be without a strictly adaptive color, so long as they are not conspicuous. In a majority of cases, however, the color is undoubtedly protective, the brown hue being of a shade that assimilates very closely to the surroundings. There are pale yellowish browns, lined and mottled, in species living amidst a sere, scanty vegetation: earthy browns, in those frequenting open sterile or stony places; while the species that creep on trees in forests are dark brown in color, and in many cases the feathers are mottled in such a manner as to make them curiously resemble the bark of a tree. The genera *lochmias* and *sclerurus* are the darkest, the plumage in these birds being nearly or quite

black, washed or tinged with rhubarb yellow. Their black plumage would render them conspicuous in the sunshine, but they pass their lives in dense tropical forests, where the sun at noon sheds only a gloomy twilight.—HUDSON *Naturalist in La Plata*, ch. 18, p. 248. (C. & H., 1895.)

47. ——— ——— *White Coloration of Arctic Animals Protective.*—In the arctic regions there are a number of animals which are wholly white all the year round, or which only turn white in winter. Among the former are the polar bear and the American polar hare, the snowy owl and the Greenland falcon; among the latter the arctic fox, the arctic hare, the ermine, and the ptarmigan. Those which are permanently white remain among the snow nearly all the year round, while those which change their color inhabit regions which are free from snow in summer. The obvious explanation of this style of coloration is that it is protective, serving to conceal the herbivorous species from their enemies, and enabling carnivorous animals to approach their prey unperceived.—WALLACE *Darwinism*, ch. 8, p. 130. (Hum., 1889.)

48. ADAPTATION OF COLOR TO HABITS—*Brilliancy of Color Possible for Female Birds in Protected Nests.*—There are considerable numbers of birds in which both sexes are similarly and brilliantly colored. Such are the extensive families of the kingfishers, the woodpeckers, the toucans, the parrots, the turacos, the hangnests, the starlings, and many other smaller groups, all the species of which are conspicuously or brilliantly colored, while in all of them the females are either colored exactly like the males, or, when differently colored, are equally conspicuous. . . . In all these cases, without exception, the species either nests in holes in the ground or in trees, or builds a domed or covered nest, so as completely to conceal the sitting-bird. We have here a case exactly parallel to that of the butterflies protected by distastefulness, whose females are either exactly like the males, or, if different, are equally conspicuous.—WALLACE *Darwinism*, ch. 10, p. 188. (Hum., 1889.)

49. ADAPTATION OF DEVICES TO CLIMATE—*Binding with Rawhide among the Eskimos.*—The peoples of the world who live north of the tree-line, and many who dwell in more temperate zones, have discovered the virtue of rawhide. The Eskimo spends many hours in cutting out miles of rawhide string, or babiche, of all degrees and sizes. This he uses in holding together not only the parts of his implements, but in manufactures of every kind. It is a marvelous substance. Frost that will snap steel nails like glass has no effect upon it. When it is put on green and allowed to dry, it shrinks nearly one-half, binding the parts immovably

Further south, as well as in the Arctic region, the tough sinew is taken from the leg of the deer. It is shredded as fine as silk, spun into yarn, and then twisted or braided into cord. This has no end of uses, not only in tool making, but in all arts where the greatest possible toughness and pliability are demanded. It serves to make a secure ferrule on the awl handle, to strengthen the bow, to hold feather and head on the arrow. It has an economic use for every day in the year.—MASON *Origins of Invention*, ch. 2, p. 41. (S., 1899.)

50. ADAPTATION OF FLOWERS TO INSECTS—*Contrivances That Guide or Force Visiting Insect to Fertilize Flower—The Labellum in Orchids.*—The labellum is by far the most important of the external envelopes of the flower. It not only secretes nectar, but is often modeled into variously shaped receptacles for holding this fluid, or is itself rendered attractive so as to be gnawed by insects. Unless the flowers were by some means rendered attractive, most of the species would be cursed with perpetual sterility. The labellum always stands in front of the rostellum, and its outer portion often serves as a landing-place for the necessary visitors. In *Epipactis palustris* this part is flexible and elastic, and apparently compels insects in retreating to brush against the rostellum. In *Cypripedium* the distal portion is folded over like the end of a slipper, and compels insects to crawl out of the flower by one of two special passages. In *Pterostylis* and a few other orchids the labellum is irritable, so that when touched it shuts the flower, leaving only a single passage by which an insect can escape. In *Spiranthes*, when the flower is fully mature, the column moves from the labellum, space being thus left for the introduction of the pollen-masses attached to the proboscis of a humblebee. In *Mormodes ignea* the labellum is perched on the summit of the column, and here insects alight and touch a sensitive point, causing the ejection of the pollen-masses. The labellum is often deeply channeled, or has guiding ridges, or is pressed closely against the column; and in a multitude of cases it approaches closely enough to render the flower tubular. By these several means insects are forced to brush against the rostellum.—DARWIN *Fertilization of Orchids*, ch. 9, p. 275. (A., 1898.)

51. ADAPTATION OF MEANS TO ENDS—*Seeming Intelligent Choice on the Part of Earthworms—Intelligence Not Limited by Size of Brain.*—To sum up, as chance does not determine the manner in which objects are drawn into the burrows, and as the existence of specialized instincts for each particular case cannot be admitted, the first and most natural supposition is that worms try all methods until they at last succeed; but many appearances are opposed to such a supposition. One alternative alone is left, namely, that worms, altho

standing low in the scale of organization, possess some degree of intelligence. This will strike every one as very improbable; but it may be doubted whether we know enough about the nervous system of the lower animals to justify our natural distrust of such a conclusion. With respect to the small size of the cerebral ganglia, we should remember what a mass of inherited knowledge, with some power of adapting means to an end, is crowded into the minute brain of a worker-ant.—DARWIN *Formation of Vegetable Mold,* ch. 2, p. 28. (Hum., 1887.)

52. ADAPTATION OF ORGANS TO MIND—*The Secret of Man's Supremacy.*—And when we remember that the immense variety of organic forms in the existing world does not exhaust the adaptability of their plan, but that the still vaster varieties of all the extinct creations have circled round the same central types, it becomes evident that these types have had from the first a purpose which has been well and wonderfully fulfilled. As a matter of fact, we see that the original conception of the framework of organic life has included in itself provisions for applying the principle of adaptation in infinite degrees. Its last development is in man. . . . There are stronger arms, there are swifter limbs, there are more powerful teeth, there are finer ears, there are sharper eyes. There are creatures which go where he cannot go, and can live where he would die. But all his members are coordinated with one power—the power of thought. Through this he has the dominion over all other created things—whilst yet as regards the type and pattern of his frame he has not a single bone or joint or organ which he does not share with some one or other of the beasts that perish. It is not in any of the parts of his structure, but in their combination and adjustment, that he stands alone.—ARGYLL *Reign of Law,* ch. 4, p. 120. (Burt.)

53. ADAPTATION OF PARALYTIC TO NEW CONDITION—*Increase of Muscular Force for Same Movement—Effect of Practise.*—A patient who is partly paralyzed in leg or arm, so that he can only move the limb with very great effort, has a distinct sensation of this effort: the limb seems heavier than it used to be, as tho weighted with lead; that is to say, there is a sensation of greater expenditure of force than before, altho the work actually done is the same or even less. For the performance of this amount of work there is required an innervation of abnormal intensity. In the same way, the patient will deceive himself, especially in the first stages of the disease, with regard to the extent of his movements. His steps are short and uncertain; his hand misses the objects which he is reaching for. By degrees, if his condition remains unchanged for a long time, he regains more or less precision of movement; practise gives him familiarity with his new system of muscle-sensations.—WUNDT *Psychology,* lect. 9, p. 136. (Son. & Co., 1896.)

54. ADAPTATION OF PLANT TO ANIMAL FOOD—*Secretion Poured Out When Object To Be Digested.*—It is a much more remarkable fact that when an object, such as a bit of meat or an insect, is placed on the disk of a leaf, as soon as the surrounding tentacles become considerably inflected, their glands pour forth an increased amount of secretion. I ascertained this by selecting leaves with equal-sized drops on the two sides, and by placing bits of meat on one side of the disk; and as soon as the tentacles on this side became much inflected, but before the glands touched the meat, the drops of secretion became larger. This was repeatedly observed, but a record was kept of only thirteen cases, in nine of which increased secretion was plainly observed; the four failures being due either to the leaves being rather torpid, or to the bits of meat being too small to cause much inflection. We must therefore conclude that the central glands, when strongly excited, transmit some influence to the glands of the circumferential tentacles, causing them to secrete more copiously.—DARWIN *Insectivorous Plants,* ch. 1, p. 11. (A., 1900.)

55. ADAPTATION, PRIMITIVE, OF HANDLES TO TOOLS—In almost every section of North America occurs the "grooved ax," and there grow a great many varieties of wood, like ash or hickory, whose saplings will bend double without breaking and will easily split. The Indians were accustomed to take a piece of one of these saplings about six feet long and split it, so that, in bending about the groove of the ax or adz or hammer, it would neatly fit. The hafting was completed by securely seizing the sides together near the working piece and at the grip. . . . This style might have been seen in the United States anywhere between the two oceans.—MASON *Origins of Invention,* ch. 2, p. 37. (S., 1899.)

56. ADAPTATION TO ENVIRONMENT BY ANIMALS—*Deep-sea Organisms with Movable Plates Adjustable to Pressure.*—In shallow-water sea-urchins the shells are composed of a great number of little plates that fit so closely to one another that no movement is possible between them. When the animal dies all the soft tissues decay and the shell remains, to be tossed about by the waves until crunched or dashed to pieces. In *Phormosoma,* however, the tiny plates of which the shell is composed are freely movable on one another, and when the animal is alive very considerable contractions and expansions can take place. None of the modern shallow-water echinoids present this peculiarity, and it is a very interesting and surprising fact that in this respect the fossils of the chalk should re-

semble so closely the living urchins of the abyss.—HICKSON *Fauna of the Deep Sea,* ch. 5, p. 102. (A., 1894.)

57. ——— ——— *Dogs Change during Growth—Heredity of Acquired Characters.*—The influence of physical conditions in modifying the constitution is well known to be most strongly exerted during the earlier period of life; for as long as the organism is in process of development it will grow to its environment, as it will not do at a later epoch, when it will either resist or succumb. We are told by Sir Charles Lyell that the Cornish miners, who went out some sixty years ago to work the Real del Monte mines in Mexico, took out some greyhounds to hunt the hares which abound on the elevated plateaux of that country; but that, in consequence of the rarefied condition of the air, the dogs could not continue the chase, but lay down panting for breath. The offspring of those dogs, however, brought up at this elevation, were able to run down the hares as well as if both had been on a lower level. The constitution of the young dogs adapted itself to the environment in which they grew up; but whence that adaptability? We do not find it in any but living organisms; no physical property gives the least account of it.—CARPENTER *Nature and Man,* lect. 15, p. 440. (A., 1889.)

58. ——— ——— *Kangaroo Must Traverse Desert Swiftly, while Its Forefeet Serve as Hands.*—Some of them [kangaroos] are very large animals, as bulky as deer, and rapidity of locomotion is especially necessary for a large animal which inhabits a country subject to such severe and widely extended droughts as is Australia. . . . In the kangaroos we have animals which require to use their front limbs for purposes of more or less delicate manipulation, with respect to the economy of the "pouch." Accordingly, for such creatures to be able to inhabit such a country, the hind limbs must by themselves answer the purpose of both the front and hind limbs of deer and antelopes. But the kangaroo's limbs are quite admirably suited to its needs. The front pair serve as prehensile manipulating organs, while the hind pair amply suffice to carry the animal over great distances and rapidly traverse wide, arid plains in pursuit of rare and distant water. —MIVART *Types of Animal Life,* ch. 2, p. 48. (L. B. & Co., 1893.)

59. ——— ——— *Lizards That Live without Water.*—The individuals [lizards of the terrestrial species of *Amblyrhyncus,* of the Galapagos Islands], and they are the greater number, which inhabit the lower country, can scarcely taste a drop of water throughout the year; but they consume much of the succulent cactus, the branches of which are occasionally broken off by the wind. I several times threw a piece to two or three of them when together; and it was amusing enough to see them trying to seize and carry it away in their mouths, like so many hungry dogs with a bone.—DARWIN *Naturalist's Voyage Around the World,* ch. 17, p. 389. (A., 1893.)

60. ——— ——— *The Sloth, as Known to Recent Science.*—Far from being an "imperfect sketch" of animal life, it [the sloth] is a fully completed study of perfect adaptation of structure to need. The sloth is an animal specially formed to dwell nowhere but in luxuriant forests. But to live thus . . . necessitates a special and peculiar structure. . . . It is impossible that an animal formed to do this can at the same time be organized so as to move well and freely on the surface of the ground, for which the stress and leverage must be altogether different. Hence the structure of such a creature must seem very defective to any one who only observes its motions on the surface of the soil, a position in which it naturally hardly if ever finds itself. . . . Sloths pass their lives hanging under the branches of trees, back downwards, and so they can sleep securely. The fingers and toes of each hand and foot are so closely bound together that they cannot be separated; while each finger and toe is furnished with an enormously long and very strong nail, greatly curved. When at rest the hands and feet are so bent that each thus forms a strong hook, and it requires an effort on the part of the animal to unhook either a hand or foot from the branch it clasps. Thus it is that the sloth can sleep suspended from a branch, and remain so after death.—MIVART *Types of Animal Life,* ch. 9, p. 249. (L. B. & Co., 1893.)

61. ——— ——— *Vast Size of Whale Possible Only for Marine Animal.*—There results a limitation of growth in a land-animal, which does not exist for an animal living in the water. If, after observing the swaying flesh of an elephant as it walks along, we consider what would happen could there be formed a land-animal equal in mass to the whale, it needs no argument to show that such a creature could not stand, much less move about. But in the water the strain put upon its structures by the weights of its various parts is almost if not quite taken away.—SPENCER *Biology,* pt. ii. ch. 1, p. 156. (A., 1900.)

62. ADAPTATION TO ENVIRONMENT BY MEN—*Arboreal Human Life—Former South American Tree-dwellers.*—This region [South American steppes], which may be regarded as peculiarly the habitation of wild animals, would not have been chosen as a place of settlement by nomadic hordes, who prefer a vegetable diet, had it not possessed some few fan-palms *(Mauritia)* scattered here and there. The beneficent qualities of this tree of life have been universally celebrated. Upon this alone subsist

the unsubdued tribe of the Guaranes, at the mouth of the Orinoco northward of the Sierra de Imataca. When they increased in numbers and became overcrowded, it is said that, besides the huts which they built on horizontal platforms supported by the stumps of felled palm-trees, they also ingeniously suspended from stem to stem spreading mats or hammocks woven of the leaf-stalk of the Mauritia, which enabled them, during the rainy season, when the Delta was overflowed, to live in trees in the manner of apes. These pendent huts were partly covered with clay. The women kindled the fire necessary for their culinary occupations on the humid flooring. As the traveler passed by night along the river, his attention was attracted by a long line of flame suspended high in the air, and apparently unconnected with the earth. The Guaranes owe the preservation of their physical, and perhaps even of their moral independence, to the loose marshy soil, over which they move with fleet and buoyant foot, and to their lofty sylvan domiciles; a sanctuary whither religious enthusiasm would hardly lead an American stylite.—HUMBOLDT *Views of Nature*, p. 12. (Bell. 1896.)

63. ADAPTATION TO LIFE-WORK—*Teeth of Beaver Self-sharpening.*—The amazing facility the beaver possesses for felling trees is due to the power of its jaws and teeth. Of these there are, as in the aye-aye, two large cutting teeth above and two below, separated by a toothless interspace from the grinding teeth behind them. Each cutting tooth is protected in front by a coating of very dense enamel, so that at its summit it wears away less quickly in front than behind, and thus a sharp, chisel-like cutting edge is constantly preserved.—MIVART *Types of Animal Life*, ch. 12, p. 352. (L. B. & Co., 1893.)

64. ADAPTATION TO SEASON—*Grouse Provided with Snowshoes in Winter.*—By far the best instance of modification in the structure of the feet is furnished by grouse. It is an unusual case of seasonal adaptation in form. During the summer the toes of grouse are bare and slender, but as these birds are largely ground-haunters, and most of them inhabit regions where the snowfall is heavy, the toes in winter acquire a comblike fringe on either side. Practically, therefore, grouse don snowshoes in the fall, and wear them until the following spring.—CHAPMAN *Bird-Life*, ch. 2, p. 27. (A., 1900.)

65. ADAPTATION TO TWO ELEMENTS AT ONCE—*Fish with Divided Eye.*—Mr. Agassiz was especially interested in seeing alive for the first time the curious fish called "tralhote" by the Indians, and known to naturalists as the *Anableps tetrophthalmus.* This name, signifying "four-eyed," is derived from the singular structure of the eye. A membranous fold enclosing the bulb of the eye stretches across the pupil, dividing the visual apparatus into an upper and lower half. No doubt this formation is intended to suit the peculiar habits of the Anableps. These fishes gather in shoals on the surface of the water, their heads resting partly above, partly below the surface, and they move by a leaping motion somewhat like that of frogs on land. Thus, half in air, half in water, they require eyes adapted for seeing in both elements, and the arrangement described above just meets this want.—AGASSIZ *Journey in Brazil*, ch. 4, p. 143. (H. M. & Co., 1896.)

66. ADAPTATION TO USE THROUGHOUT NATURE—*Darwinism Involves a New Teleology.*—Adaptation to use, altho the very essence of Darwinism, is not a fixed and inflexible adaptation, realized once for all at the outset; it includes a long progression and succession of modifications, adjusting themselves to changing circumstances, under which they may be more and more diversified, specialized, and in a just sense perfected. Now, the question is, does this involve the destruction or only the reconstruction of our consecrated ideas of teleology? Is it compatible with our seemingly inborn conception of nature as an ordered system? Furthermore, and above all, can the Darwinian theory itself dispense with the idea of purpose, in the ordinary sense of the word, as tantamount to design.—ASA GRAY *Darwiniana*, art. 13, p. 358. (A., 1889.)

67. ADAPTATIONS IN BIRD-STRUCTURE CUMULATIVE—*All Converged on the Power of Flight—Not Less Designed Because a Growth.*—Now if, in examining the structure of a typical bird, we find evidences of "design" in the wonderful adaptation of its clothing of feathers alike to keep in the warmth of the body, and to sustain it in its flight through the air—in that organization of its heart and lungs which enables them to keep up the energetic circulation and respiration required for the maintenance of a high standard of muscular activity—in those arrangements of the skeleton and muscular apparatus which give support and motion to the expanded wings—in the adaptation of the eye to that acute and far-ranging vision which is needed for the guidance of its actions—and in many other provisions I might enumerate—I affirm, without any doubt of your assent, that this evidence is not in the least degree invalidated by the discovery that the germ-particle is not a miniature bird, but a protoplasmic "jelly-speck." In its capacity for "evolution" into the complete type, the germ-particle is just as much "potentially" the bird as if it could become one by merely swelling out.—CARPENTER *Nature and Man*, lect. 15, p. 432. (A., 1889.)

68. ADAPTATIONS MANIFOLD IN NATURE—*One Part Serves Many Purposes.*—Altho an organ may not have been originally

formed for some special purpose, if it now serves for this end we are justified in saying that it is specially adapted for it. On the same principle, if a man were to make a machine for some special purpose, but were to use old wheels, springs, and pulleys, only slightly altered, the whole machine, with all its parts, might be said to be specially contrived for its present purpose. Thus throughout nature almost every part of each living being has probably served, in a slightly modified condition, for diverse purposes, and has acted in the living machinery of many ancient and distinct specific forms.—DARWIN *Fertilization of Orchids*, ch. 9, p. 283. (A., 1898.)

69. ADAPTIVENESS OF HUMAN ORGANISM—*Acquired Automatism—Houdin's Play with Balls.*—The extraordinary adaptiveness of the organism of man is shown in his power of acquiring a vast number of more special actions, which have no direct relation to his bodily wants, but minister to requirements of his own creation. These often become, by a process of prolonged "training," not less automatic than the act of walking; as is shown by the fact that, when once set going, they will continue in regular sequence, not only without any volitional exertion, but whilst the attention is wholly directed elsewhere. . . . With a view of cultivating the rapidity of visual and tactile perception, and the precision of respondent movements, which are necessary for success in every kind of "prestidigitation," Houdin early practised the art of juggling with balls in the air; and having, after a month's practice, become thorough master of the art of keeping up four balls at once, he placed a book before him, and, while the balls were in the air, accustomed himself to read without hesitation.—CARPENTER *Mental Physiology*, ch. 5, p. 217. (A., 1900.)

70. ADAPTIVENESS OF NATURE—*Wings for Other Use than Flight—Penguin—"Steamer"—Ostrich.*—In these [Falkland] islands a great loggerheaded duck or goose . . . is very abundant. . . . They are named, appropriately, steamers. Their wings are too small and weak to allow of flight, but by their aid, partly swimming and partly flapping the surface of the water, they move very quickly. These clumsy, loggerheaded ducks make such a noise and splashing that the effect is exceedingly curious. Thus we find in South America three birds which use their wings for other purposes besides flight: the penguin as fins, the steamer as paddles, and the ostrich as sails; and the apteryx of New Zealand, as well as its gigantic extinct prototype the deinornis, possess only rudimentary representatives of wings.—DARWIN *Naturalist's Voyage Around the World*, ch. 9, p. 200. (A., 1898.)

71. ADJUSTMENT OF AERIAL TEMPERATURE—*Dead-line of Cold Just Overhangs Zone of Life—Earth's Heat Not Greatly Changed through Geologic Ages.*—It is not easy to appreciate the delicacy of adjustment which is required to establish this temperature demanded by organic life, and to maintain it through the geological ages. Even in the permanent heat of the equator the zone of life-killing cold lies but four miles above the surface of the sea. As soon as night comes on, this dead-line begins to descend toward the surface; by morning it may have fallen to within three miles of the sea-level. A week of continued night would lock the tropics in a deadly frost and make an end of its land-life.—SHALER *Aspects of the Earth*, p. 201. (S., 1900.)

72. ADJUSTMENT OF CHEMICAL AFFINITIES IN THE BODY—*Life Supreme.*—There is indeed an adjustment—a close and intricate adjustment—between the chemical affinities of these elements as they are combined in the living body; but it is an adjustment of them under the controlling energy of a power which cannot be identified with any other, and which always presents phenomena peculiar to itself. Under that power we see that the laws and forces of chemical affinity, as exhibited apart from life, are held, as it were, to service—compelled, indeed, to minister, but not allowed to rule. Through an infinite variety of organisms this mysterious subordination is maintained, ministering through an ascending series to higher and higher grades of sensation, perception, consciousness, and thought.—ARGYLL *Unity of Nature*, ch. 2, p. 34. (Burt.)

73. ADJUSTMENT OF MENTAL FORCES—*Conduct Determined by Combination of Motives.*—It is true, indeed, that there are in the mind of man, as there are in nature, certain forces originally implanted which are unchangeable in this sense, that they have an invariable tendency to determine conduct in a particular direction. But as in nature we have a power of commanding her elementary forces by the methods of adjustment, so in the realm of mind we can operate on the same principle, by setting one motive to counteract another: and by combination among many motives we can influence in a degree, and to an extent as yet unknown, the conduct and the condition of mankind.—ARGYLL *Reign of Law*, ch. 7, p. 219. (Burt.)

74. ADJUSTMENT OF ORGANISM TO ENVIRONMENT—*Wing-feathers and Auriculars in Birds—Internal vs. External Correlation.*—There are two correlations of growth in respect to feathers which are constant. In all cases (excepting, of course, the wingless birds) the feathers which grow from the forearm and finger-bones, constituting the wings, are comparatively long, strong, tapering, elastic, and with thin lateral filaments, which filaments are closely hooked together by means of minute

teeth fitting into each other, so that the whole shall form one continuous surface or web. This is a correlation of growth between one particular kind of feather and one particular member of the body, which, in all birds capable of flight, is constant, and amounts to a universal law. Now let us contrast this with another correlation of growth which is equally constant. On the side of the head of all birds there is a patch of feathers of peculiar structure, with fine and slender shafts, and with the lateral filaments not hooked together as in the other case, but, on the contrary, always separated from each other—the whole series forming a fine and open network spread over the surface which they cover and protect. These feathers cover the orifice of the ear, and are called the auriculars. They are correlated with the curious passages, the finely hung clapper-bones, and all the elaborate mechanism of that organ. Such are the internal correlations. But they are intelligible only when considered in the light shed by other correlations which are external. The wing-feathers, with close continuous webs, are correlated to the laws by which the passage of air may be prevented; the auricular feathers, with open unconnected webs, are correlated to the laws by which the passage of sound may be rendered easy. The one set of feathers is adapted to the active function of evoking and resisting atmospheric pressure by striking strong, yet light and elastic blows, upon the air; the other set of feathers is adapted to the passive function of allowing the free access of the waves of sound into the passages of the ear. These are but a few examples out of millions. Throughout the whole range of nature the system of internal correlation is entirely subordinate to the system of external correlation.—ARGYLL *Reign of Law*, ch. 5, p. 151. (Burt.)

75. ADJUSTMENT OF ORGANS FOR MUSICAL EFFECT—*A Natural Violin—The Mole-cricket.*—If one walks in the meadows along a little brook on a fine June evening, he will often hear a long-sustained note, even, subdued, and pleasant, which vibrates powerfully without swelling or diminishing, somewhat like that of the nightingale in Haydn's "Toy Symphony." A cautious approach will enable us to see a mole-cricket sitting, apparently motionless, in front of its hole in the ground. More careful examination proves that the short wing-covers are in a state of continual vibration, producing friction as they move; and this it is which causes the sound. The microscope shows that minute and delicate teeth are placed at regular intervals along a vein on one of the wing-covers; when these are struck at a certain rate by a vein on the other wing, they emit a whirring note of a definite pitch. One vein acts as the bow, the other as the string of a violin; the mole-cricket is a violinist, and can therefore hold on its note as long as it will.—WEISSMAN *Heredity*, vol. ii, p. 34. (Cl. P., 1892.)

76. ADJUSTMENT OF SOUL TO THE NON-EXISTENT—*A Breach of Continuity—Would Violate All Analogy of Nature.*—Now if the relation thus established in the morning twilight of man's existence between the human soul and a world invisible and immaterial is a relation of which only the subjective term is real and the objective term is non-existent, then, I say, it is something utterly without precedent in the whole history of creation. All the analogies of evolution, so far as we have yet been able to decipher it, are overwhelmingly against any such supposition. To suppose that during countless ages, from the sea-weed up to man, the progress of life was achieved through adjustments to external realities, but that then the method was all at once changed and throughout a vast province of evolution the end was secured through adjustments to external non-realities, is to do sheer violence to logic and to common sense.—FISKE *Through Nature to God*, pt. iii, ch. 10, p. 189. (H. M. & Co., 1900.)

77. ADJUSTMENT OF VISION TO DISTANCE—*Adaptation Automatic and Unconscious.*—Mark, now, the superiority of the eye. In its normal condition this wonderful organ possesses a power to which no optical instrument of human construction can show the remotest parallelism—that of adjusting itself to differences of focal distance. Thus, if I close one eye, and hold up my finger between my other eye and the clock at the far end of the room, I cannot see both of them distinctly at the same time, because, as they are at different distances from my eye, their pictures on my retina cannot both be distinct. But, without moving either my head or my eye, I can so "focus" my eye on either as to see it distinctly, the other becoming hazy. This we all constantly do without the least knowledge of the mechanism by which it is effected: and all that the most careful and refined investigation has revealed to the physiologist is that the focal adjustment is made by a change in the curvature of the crystalline lens; its curvature being increased when the rays that fall upon it are more divergent, because proceeding from a nearer object; and being diminished when the rays, proceeding from a more distant object, are less divergent—so as in each case to bring them to a focus on the retina. This change of curvature is produced, it is believed, by the action of the ciliary muscle which surrounds the lens; but how that action is called forth we do not know. Indeed, we are quite unconscious that we are putting it into contraction. I simply determine, "I will look at the clock," or, "I will look at my finger," and my eye adjusts itself accordingly. If, on the other hand, I were to look with a telescope, first at a watch-face a few feet off, and then at a

church-clock at a distance, I should have to diminish the distance between the object-glass and the eye-piece; and I cannot conceive of any optical mechanism by which the telescope could be enabled to make this adjustment for itself. That the eye should be provided with such a mechanism has always seemed to me a most wonderful evidence of intelligent design; and the importance of this provision in our daily life is so great (as every one knows in whom it is even partially deficient) as to outweigh beyond all comparison the slight want of optical perfection which . . . is inseparable from it.—CARPENTER *Nature and Man*, lect. 15, p. 425.

78. ADVANCE ALONG ABORIGINAL LINES—*Improvement in Mechanic Arts—Perfected Snow-shoes.*—The Canadian Indians and those of the northern United States, having only soft material and bark to work upon, restrict themselves mostly to the long-bladed curved knife. On the Pacific coast, among Indian tribes from Mount St. Elias and southward, there is a mixture of hard material and soft wood, so that there is a great variety in the form of the whittler's knife. Furthermore, these tribes have been in contact with sailors for more than a century, and use any piece of steel or iron they can secure in trade. The Canadian Indians were stimulated by the fur-trading companies to travel more rapidly and to make longer journeys; hence, in furnishing them with the curved knife, they made it possible for these Indians to work out the frame of the birch-bark canoe, the bows of the snow-shoes, splints for basketry, and a thousand and one objects made of birch-bark, with this simple but most efficient device. It has become the traveling tool of the Canadian Indians and has done more than aught else to improve their mechanical skill. An examination of old patterns of snow-shoes, in comparison with the latest patterns, reveals an astonishing improvement. The versatile curved knife is just as useful in the making of fine babiche or rawhide string for the webbing of the snow-shoe as in whittling down the frame. In the old-fashioned snow-shoes the rawhide footing is nearly one-fourth inch wide, while in the best and latest the strands are as fine as thread.—MASON *The Man's Knife Among the North American Indians, (Report of the U. S. National Museum)*, p. 732.

79. ADVANCE FROM KNOWN TO UNKNOWN—*Acquaintance with Phenomena of Sound-waves Led to Discovery of Waves of Light—Young Demonstrates the Undulatory Theory.*—In the year 1773 was born, at Milverton, in Somersetshire, one of the most remarkable men that England ever produced. He [Thomas Young] was educated for the profession of a physician, but was too strong to be tied down to professional routine. He devoted himself to the study of natural philosophy, and became in all its departments a master. He was also a master of letters. Languages, ancient and modern, were housed within his brain, and, to use the words of his epitaph, "he first penetrated the obscurity which had veiled for ages the hieroglyphics of Egypt." It fell to the lot of this man to discover facts in optics which Newton's theory was incompetent to explain, and his mind roamed in search of a sufficient theory. He had made himself acquainted with all the phenomena of wave-motion; with all the phenomena of sound; working successfully in this domain as an original discoverer. Thus informed and disciplined, he was prepared to detect any resemblance which might reveal itself between the phenomena of light and those of wave-motion. Such resemblances he did detect; and, spurred on by the discovery, he pursued his speculations and his experiments until he finally succeeded in placing on an immovable basis the undulatory theory of light.—TYNDALL *Lectures on Light*, lect. 2, p. 50. (A., 1898.)

80. ADVANCE IN OUR KNOWLEDGE OF LIVING ORGANISMS—*Inadequate Early Estimates.*—The species known to the naturalists of early times were few in number—at least, comparatively—and the old students had no idea of the excessive diversity of form and structure familiar to us. A census of animals and plants was taken by Ray [1670-93] shortly before Linnæus commenced his career, and enumerated less than 4,000 animals, exclusive of insects; and of those it was estimated that there were about "20,000 in the whole world." He evidently believed that the entire number living would not be found greatly to exceed this. But let Ray speak for himself. According to the author's classification, animals were divided into four orders—"beasts, birds, fishes, and insects." The number of beasts, including also serpents, that had been accurately described, he estimated at not above 150, adding that, according to his belief, "not many that are of any considerable bigness, in the known regions of the world, have escaped the cognizance of the curious." (At the present day more than 7,000 species of "beasts," reptiles, and amphibians have been described.) The number of birds "may be near 500; and the number of fishes, excluding shell-fish, as many; but, if the shell-fish be taken in, more than six times the number." As to the species remaining undiscovered, he supposed "the whole sum of beasts and birds to exceed by a third part, and fishes by one-half, those known." The number of insects—that is, of animals not included in the above classes—he estimated at 2,000 in Britain alone, and 20,000 in the whole world. . . . About 375,000 species of animals are now known, and of insects we still know the smaller portion. . . . The late Dr. C. V. Riley even went so far as to say "that there are 10,000,000 species of

insects in the world would be, in [his] judgment, a moderate estimate." The largest previous estimate, by Sharp and Walsingham, 2,000,000, was termed by Riley "extremely low."—GILL *Address before the Am. Assoc. for the Advancement of Science, Smithsonian Report for 1896*, pp. 457-483.

81. ADVANCE IN SCIENCE—*The Joy of Its Study Alike in All Ages.*—Each of these epochs of the contemplation of the external world—the earliest dawn of thought and the advanced stage of civilization—has its own source of enjoyment. In the former, this enjoyment, in accordance with the simplicity of the primitive ages, flowed from an intuitive feeling of the order that was proclaimed by the invariable and successive reappearance of the heavenly bodies, and by the progressive development of organized beings; while in the latter, this sense of enjoyment springs from a definite knowledge of the phenomena of nature. When man began to interrogate nature, and, not content with observing, learned to evoke phenomena under definite conditions; when once he sought to collect and record facts, in order that the fruit of his labors might aid investigation after his own brief existence had passed away, the philosophy of nature cast aside the vague and poetic garb in which she had been enveloped from her origin, and, having assumed a severer aspect, she now weighs the value of observations, and substitutes induction and reasoning for conjecture and assumption.—HUMBOLDT *Cosmos*, vol. i, int., p. 24. (H., 1897.)

82. ADVANCE IN TYPE—*None Since the Mammalia Were Reached—The Mothers Stand Now at the Top.*—What was that pinnacle? There is no more instructive question in science. For the answer brings into relief one of the expression-points of nature—one of these great teleological notes of which the natural order is so full, and of which this is by far the most impressive. Run the eye for a moment up the scale of animal life. At the bottom are the first animals, the Protozoa. The Cœlenterata follow, then in mixed array the Echinoderms, Worms, and Mollusks. Above these come the Pisces, then the Amphibia, then the Reptilia, then the Aves, then—what? The Mammalia, THE MOTHERS. There the series stops. Nature has never made anything since.—DRUMMOND *Ascent of Man*, p. 267. (J. P., 1900.)

83. ADVANCE OF CIVILIZATION—*Epoch-making Ideas.*—Those are happy hours to most of us when we recall the days of childhood. To trace the lives of celebrated men and women to the springs of their moral and intellectual power brings never-fading delight. To study the rise and progress of a nation or any social unit is worthy of exalted minds. But the most profitable inquiry of all is the search for the origin of epoch-making ideas in order to comprehend the history of civilization, to conjure up those race memories in which each people transmits to itself and to posterity its former experiences.—MASON *The Birth of Invention (Address at Centenary of American Patent System, Washington, 1891*, proceedings), p. 403.

84. ADVANCE OF GLACIERS IN RECENT TIMES—*Road Buried under Ice.*—We have ample traditional evidence of the oscillations of glacier-boundaries in recent times. During the religious wars of the sixteenth century, when the Catholics gained the ascendency in the Canton of Valais, the inhabitants of the upper valleys adhered to the Protestant faith. Shut out from ordinary communication with the Protestant churches by the Bernese Oberland, the account states that these peasants braved every obstacle to the exercise of their religion, and used to carry their children over a certain road by the valley of Viesch, across the Alps, to be baptized at Grindelwald, on the farther side of the glaciers of Aletsch and Viesch. I could not understand this statement, for no such road exists, or could be conceived possible at present; nor was there any knowledge of it among the guides, intimate as they are with every feature of the region. Impressed, however, with the idea that there must be some foundation for the statement, I carefully examined the ground, and, penetrating under the glacier of Aletsch, I actually found, a number of feet below the present level of the ice, the paved road along which these hardy people traveled to church with their children, and some traces of which are still visible. It has been almost completely buried, altho here and there it reappears; but at this day it is completely impassable for ordinary travel.—AGASSIZ *Geological Sketches*, ser. ii, p. 10. (H. M. & Co., 1896.)

85. ADVANCE OF INTELLECT PREPARES FOR NEW DISCOVERY—*A Great Period Sustains Great Men.*—All great discoveries are duly prepared for in two ways: first, by other discoveries which form their prelude; and, secondly, by the sharpening of the inquiring intellect. Thus Ptolemy grew out of Hipparchus, Copernicus out of both, Kepler out of all three, and Newton out of all the four. Newton did not rise suddenly from the sea-level of the intellect to his amazing elevation. At the time that he appeared, the table-land of knowledge was already high. He juts, it is true, above the table-land, as a massive peak; still he is supported by it, and a great part of his absolute height is the height of humanity in his time. It is thus with the discoveries of Kirchhoff. Much had been previously accomplished; this he mastered, and then by the force of individual genius went beyond it. He replaced uncertainty by certainty, vagueness by definiteness, confusion by or-

der; and I do not think that Newton has a surer claim to the discoveries that have made his name immortal than Kirchhoff has to the credit of gathering up the fragmentary knowledge of his time, of vastly extending it, and of infusing into it the life of great principles.—TYNDALL *Lectures on Light*, lect. 6, p. 206. (A., 1898.)

86. ADVANCE OF LEARNING IN SEVENTEENTH CENTURY—*A Galaxy of Discoveries.*—A few names will suffice to give an idea of the gigantic strides with which the human mind advanced in the seventeenth century, especially in the development of mathematical induction, under the influence of its own subjective force rather than from the incitement of outward circumstances. The laws which control the fall of bodies and the motions of the planets were now recognized. The pressure of the atmosphere; the propagation of light, and its refraction and polarization, were investigated. Mathematical physics were created, and based on a firm foundation. The invention of the infinitesimal calculus characterizes the close of the century; and, strengthened by its aid, human understanding has been enabled, during the succeeding century and a half, successfully to venture on the solution of the problems presented by the perturbations of the heavenly bodies; by the polarization and interference of the waves of light; by the radiation of heat; by electro-magnetic reentering currents; by vibrating chords and surfaces; by the capillary attraction of narrow tubes; and by many other natural phenomena. Henceforward the work in the world of thought progresses uninterruptedly, each portion continually contributing its aid to the remainder.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 302. (H., 1897.)

87. ADVANCE OF PHOTOGRAPHY—*Stars Revealed That Are Invisible Even through the Telescope.*—Celestial photography is not yet fifty years old; yet its earliest beginnings already seem centuries behind its present performances. . . . The chemical plate has two advantages over the human retina. First, it is sensitive to rays which are utterly powerless to produce any visual effect; next, it can accumulate impressions almost indefinitely, while from the retina they fade after one-tenth part of a second, leaving it a continually renewed *tabula rasa*. It is accordingly quite possible to photograph objects so faint as to be altogether beyond the power of any telescope to reveal; and we may thus eventually learn whether a blank space in the sky truly represents the end of the stellar universe in that direction, or whether farther and farther worlds roll and shine beyond, veiled in the obscurity of immeasurable distance.—CLERKE *History of Astronomy*, pt. ii, ch. 13, p. 524. (Bl., 1893.)

88. ADVANCE OF PRIMITIVE MAN—*From the Stone Age to a Better Stone Age—The Smoothed and Sharpened Tool Slowly Attained—Nature the First Artificer.*—The next step from the stone age, so far as further appeal to ancient implements can guide us, is also exactly what one would expect. It is to a better stone age. Two distinct grades of stone implements are found, the rough and the smooth, or the unground and the ground. For a long period the idea never seems to have dawned that a smooth stone made a better ax than a rough one. Mind was as yet unequal to this small discovery, and there are vast remains representing long intervals of time where all the stone implements and tools are of the unground type. Even when the hour did come, when savage vied with savage in putting the finest polish on his flints, his inspiration probably came from nature. The first lapidary was the sea; the smoothed pebble on the beach, or the rounded stone of the mountain stream, supplied the pattern.—DRUMMOND *Ascent of Man*, p. 140. (J. P., 1900.)

89. ADVANCE OF SOLAR PHOTOGRAPHY—*Incessant Record of the Sun by Its Own Light.*—The first solar light-pictures of real value were taken, and the autographic record of the solar condition recommended by Sir John Herschel was commenced and continued at Kew during fourteen years—1858-72. The work of photographing the sun is now carried on in every quarter of the globe, from the Mauritius to Massachusetts, and the days are few indeed on which the self-betrayal of the camera can be evaded by our chief luminary. In the year 1883 the incorporation of Indian with Greenwich pictures afforded a record of the state of the solar surface on 340 days; and 360 were similarly provided for in 1885.—CLERKE *History of Astronomy*, pt. ii, ch. 2, p. 191. (Bl., 1893.)

90. ADVANCE THROUGH STRUGGLE—*Sentence of Death on All Who Fail.*—We find that this hideous hatred and strife, this wholesale famine and death, furnish the indispensable conditions for the evolution of higher and higher types of life. Nay, more; but for the pitiless destruction of all individuals that fall short of a certain degree of fitness to the circumstances of life into which they are born, the type would inevitably degenerate, the life would become lower and meaner in kind. Increase in richness, variety, complexity of life is gained only by the selection of variations above or beyond a certain mean, and the prompt execution of a death sentence upon all the rest. —FISKE *Through Nature to God*, pt. ii, ch. 2, p. 65. (H. L. & Co., 1900.)

91. ADVANTAGE OF DIMINISHED LIGHT OF STARS—If the entire vault of heaven were covered with innumerable strata of stars, one behind the other, as with a wide-spread starry canopy, and light were undiminished in its passage through space, the sun would be distinguishable only by its

spots, the moon would appear as a dark disk, and amid the general blaze not a single constellation would be visible.—HUMBOLDT *Cosmos*, vol. iii, p. 103. (H., 1897.)

92. ADVANTAGE OF TROPICS FOR NATURE-STUDY—*All Forms Represented—Climates Ranged Stage by Stage on Mountainsides.*—The countries bordering on the equator possess another advantage. . . . This portion of the surface of the globe affords in the smallest space the greatest possible variety of impressions from the contemplation of nature. Among the colossal mountains of Cundinamarca, of Quito, and of Peru, furrowed by deep ravines, man is enabled to contemplate alike all the families of plants, and all the stars of the firmament. There, at a single glance, the eye surveys majestic palms, humid forests of bambusa, and the varied species of musaceæ, while above these forms of tropical vegetation appear oaks, medlars, the sweet-brier, and umbelliferous plants, as in our European homes. There, as the traveler turns his eyes to the vault of heaven, a single glance embraces the constellation of the Southern Cross, the Magellanic clouds, and the guiding stars of the constellation of the Bear, as they circle round the arctic pole. There the depths of the earth and the vaults of heaven display all the richness of their forms and the variety of their phenomena. There the different climates are ranged the one above the other, stage by stage, like the vegetable zones, whose succession they limit; and there the observer may readily trace the laws that regulate the diminution of heat, as they stand indelibly inscribed on the rocky walls and abrupt declivities of the Cordilleras.—HUMBOLDT *Cosmos*, vol. i. int., p. 32. (H., 1897.)

93. ADVANTAGES OF NORTH AMERICA FOR COMMERCE—*Command of Two Oceans—Abundant Harbors.*—North America, and particularly the part of it held by the United States, is more advantageously placed in relation to marine navigation than any other equally extensive portion of the lands of the earth. Owing to the shape and position of this continent, it faces the two great divisions of oceanic waters, the Atlantic and the Pacific, and nearly all parts of its area are readily accessible from the shore by rivers or relatively short railways. At no point on its coast-line do we find a stretch of shore of more than three hundred miles in length which is without a haven suitable for modern shipping or which cannot readily be made into a good harbor.—SHALER *Sea and Land*, p. 159. (S., 1894.)

94. ADVANTAGES OF THE SPECTROSCOPE—*Chromosphere of Sun Studied without Waiting for Eclipse.*—Until recently, the solar atmosphere could be seen only at an eclipse, when the sun itself is hidden by the moon. Now, however, the spectroscope has brought the chromosphere and the prominences within the range of daily observation, so that they can be studied with nearly the same facility as the spots and faculæ, and a fresh field of great interest and importance is thus opened to science. It seems hardly possible that the ancients should have failed to notice, even with the naked eye, in some one of the many eclipses on record, the presence of blazing starlike objects, around the edge of the moon, but we find no mention of anything of the kind, altho the corona is described as we see it now.—YOUNG *The Sun*, ch. 6, p. 193. (A., 1898.)

95. ADVANTAGES TRANSMITTED BY HEREDITY—*Improvement by Breeding from Best Specimens.*—If we grow plants from seed or breed any kind of animals year after year, consuming or giving away all the increase we do not wish to keep just as they come to hand, our plants or animals will continue much the same; but if every year we carefully save the best seed to sow and the finest or brightest colored animals to breed from, we shall soon find that an improvement will take place, and that the average quality of our stock will be raised. This is the way in which all our fine garden fruits and vegetables and flowers have been produced, as well as all our splendid breeds of domestic animals; and they have thus become in many cases so different from the wild races from which they originally sprang as to be hardly recognizable as the same. It is therefore proved that if any particular kind of variation is preserved and bred from, the variation itself goes on increasing in amount to an enormous extent; and the bearing of this on the question of the origin of species is most important.—WALLACE *Darwinism*, ch. 1, p. 8. (Hum., 1889.)

96. AERONAUT, SPIDER AS—*Ascending Current in Still Air.*—One day, at Santa Fé, a spider which was about three-tenths of an inch in length, and which in its general appearance resembled a citigrade (therefore quite different from the gossamer), while standing on the summit of a post, darted forth four or five threads from its spinners. These, glittering in the sunshine, might be compared to diverging rays of light; they were not, however, straight, but in undulations like films of silk blown by the wind. They were more than a yard in length, and diverged in an ascending direction from the orifices. The spider then suddenly let go its hold of the post, and was quickly borne out of sight. The day was hot and apparently quite calm; yet under such circumstances the atmosphere can never be so tranquil as not to affect a vane so delicate as the thread of a spider's web. If during a warm day we look either at the shadow of any object cast on a bank, or over a level plain at a distant landmark, the effect of an ascending current of heated air

is almost always evident: such upward currents, it has been remarked, are also shown by the ascent of soap-bubbles, which will not rise in an indoors room. Hence I think there is not much difficulty in understanding the ascent of the fine lines projected from a spider's spinners, and afterwards of the spider itself.—DARWIN *Naturalist's Voyage Around the World*, ch. 8, p. 161. (A., 1898.)

97. AFFECTION AMONG PRIMITIVE PEOPLES—*Caribs, Papuans, Kurubars—Conflicting Reports of Observers.*—Under favorable circumstances, where food is not too scarce nor war too wasting, the life of low barbaric races may be in its rude way good and happy. In the West Indian islands, where Columbus first landed, lived tribes who have been called the most gentle and benevolent of the human race. Schomburgk, the traveler, who knew the warlike Caribs well in their home life, draws a paradise-like picture of their ways, where they have not been corrupted by the vices of the white men; he saw among them peace and cheerfulness and simple family affection, unvarnished friendship, and gratitude. . . . At the other side of the world, in New Guinea, Kops, the Dutch explorer, gives much the same account of the Papuans of Dory, who live in houses built on piles in the water, like the old lake-men of Switzerland; he speaks of their mild disposition, their inclination to right and justice, their strong moral principles, their respect for the aged and love for their children, their living without fastenings to their houses—for theft is considered by them a grave offense, and rarely occurs. Among the rude non-Hindu tribes of India, English officials have often recorded with wonder the kindliness and cheerfulness of the rude men of the mountains and the jungle, and their utter honesty in word and deed. Thus Sir Walter Elliot mentions a low poor tribe of South India, whom the farmers employ to guard their fields, well knowing that they would starve rather than steal the grain in their charge. [Their veracity is proverbial.] Of course, these accounts of Caribs and Papuans show them on the friendly side, while those who have fought with them call them monsters of ferocity and treachery. But cruelty and cunning in war seem to them right and praiseworthy; and what we are here looking at is their home peace-life. It is clear that low barbarians may live among themselves under a fairly high moral standard, and this is the more instructive because it shows what may be called natural morality. —TYLOR *Anthropology*, ch. 16, p. 406. (A., 1899.)

98. AFFECTION, CONJUGAL, WANTING AMONG SAVAGES—*Of Slow Growth in Civilization—Australian — Brahman.*—We have another and a more serious count against early fatherhood. If the love of father for child was in this backward state, infinitely more grave was the condition of things between him and the mother. Probably we have all taken it for granted that husbands and wives have always loved one another. . . . There have been and still are tribes and nations where love between husband and wife is non-existent. Among the Hovas, we are assured by authorities, the idea of love between husband and wife is "hardly thought of"; that at Winnebah "not even the appearance of affection" exists between them; that among the Beni-Amer it is "considered even disgraceful for a wife to show any affection for her husband"; that the Chittagong Hill tribes have "no idea of tenderness nor of chivalrous devotion"; and that the Eskimo treat their wives "with great coldness and neglect." The savage cruelty with which wives are treated by the Australian aborigines is indicated even in their weapons. The very names, "servant, slave," by which the Brahman address their wives, and the wife's reply, "master, lord," symbolize the gulf between the two. There are exceptions, it is true, and often touching exceptions. Travelers cite instances of constancy among savage peoples which reach the region of romance. Probably there never was a time, indeed, nor a race, when some measure of sympathy did not stir between husband and wife. But when we consider all the facts, it is impossible to doubt that in the region of all the higher affections the savage wife and the savage husband were all but strangers to each other.—DRUMMOND *Ascent of Man*, p. 300. (J. P., 1900.)

99. AFFECTIONS, ORGANIC, ACT UPON THE MIND—*Hopefulness of Consumptives Due to Accelerated Breathing.*—It is natural to suppose that the passion which a particular organ produces in the mind will be that which, when otherwise excited, discharges itself specially upon that organ. . . . When we consider the effects which a joyful anticipation, or the elation of a present excitement, has upon the lungs—the accelerated breathing and the general bodily exhilaration which it occasions—we cannot help thinking of the strange hopefulness and the sanguine expectations of the consumptive patient, who, on the edge of the grave, projects, without a shadow of distrust, what he will do long after he will have been "green in death and festering in his shroud." Observe how fear strikes the heart, and what anxious fear and apprehension accompany some affections of the heart. Anger, disappointment, and envy notably touch the liver; which, in its turn, when deranged, engenders a gloomy tone of mind through which all things have a malignant look, and from which, when philosophy avails not to free us, the restoration of its functions will yield instant relief. The internal organs are plainly not the agents of their special functions only, but, by reason of the intimate consent or sympathy of

functions, they are essential constituents of our mental life.—MAUDSLEY *Body and Mind,* lect. 1, p. 37. (A., 1898.)

100. AFFINITY, CHEMICAL, AND ELECTRICITY—Any chemical reaction which occurs between conducting substances may be utilized to generate electric currents. The chemical affinity both supplies and measures exactly the electro-motive force—BENJAMIN *Age of Electricity,* ch. 4, p. 41. (S., 1897.)

101. AFFLICTION MAY STRENGTHEN—*People of Iceland—Many Perils and High Achievement.*—Care must be taken not to make too much account of the effect exercised by the great convulsions of nature on the moral condition of a people. The need of this precaution is well shown by the social history of Iceland. This country has for the thousand years of its history been subjected to imminent peril from the instability of the earth as well as from the inhospitable nature of its climate. In almost every century of the world's history famine caused by the accidents of the earth and air has menaced the life of the population. Many successive volcanic outbreaks, attended by serious earthquakes, have convulsed this island, and yet amid these mishaps the people have maintained the highest measure of social order in any state of which we have a history. The Icelanders have had the moral strength to rise superior to such afflictions. In this state, as in certain individuals, chastisement which would have destroyed weaker natures served to affirm the vigor of the strong people.—SHALER *Aspects of the Earth,* p. 20. (S., 1900.)

102. AGENCY, HUMAN, RECOGNIZED IN ARROW-HEAD—*Instant Conviction of Its Human Origin.*—Many years ago, as I was walking in a garden in the neighborhood of Edinburgh, my eye wandered over the materials which had been freshly scattered on the path. Suddenly, and very unexpectedly, it lighted on a fragment unlike the rest, and unlike them in a way which instantly carried its own explanation on its face. All the other fragments were works of nature. This one fragment was certainly a work of human art. It was a very small, but a very perfect arrow-head, made of yellow flint. What was it that made its artificial origin so obvious at a glance? The physical forces of nature, it is true, had made it; but they had made it under special direction and control. The physical forces of nature, working by themselves, under no special direction or control, could never have made that arrow-head. No mere splitting by frost, no mere chipping by accidental collision with other fragments, still less any wearing by rivers or by the sea, could possibly have molded that perfect symmetry of form, with its sharpened point, with its two lateral barbs, and with the little shank between them. But all this reasoning was an afterthought. In coming to my conclusion, I was not conscious of any reasoning. The recognition was instantaneous. It was the recognition in that fragment, alone of all the fragments round it, of two things which of all others are the most familiar to us. The first of these was the adaptation of material and of form to a known end, and the second of these was that particular mechanical method by which the particular animal man makes the adaptations he intends.—ARGYLL *Unity of Nature,* ch. 5, p. 106. (Burt.)

103. AGENCY MANIFEST—*The Wrong Agent Suspected—The Scattering of Its Seeds by Wistaria.*—In December, while absent from home, I collected for future study some pods of the Chinese wistaria, and left them on my desk in the library for the night. The house was heated by a hot-air furnace. In the morning the pods were in great confusion; most of them had split and curled up, and the seeds were scattered all about the room. As usual the little daughter, an only child, was accused of spoiling my specimens, but she showed her innocence. A little investigation and a few experiments with some pods not yet opened explained the whole matter satisfactorily. The stout pods grow and ripen in a highly strained condition, with a strong tendency to burst spirally, the two half-pods being ready to coil and spring in opposite directions; when the valves can no longer hold together, they snap with a sharp noise and sling the heavy seeds, giving them a good send-off into the world. As a pair of birds built a nest, hatch eggs, rear their young, and then send them forth to seek their fortunes, so for months the mother plant had labored, had produced and matured seeds, which at last it scattered broadcast.—BEAL *Seed Dispersal,* ch. 6, p. 58. (G. & Co., 1898.)

104. AGENCY OF CONTRASTED FORCES IN UNITED WORK—*Fire and Water Jointly Build the Crust of the Earth.*—Water is a very active agent of destruction, but it works over again the materials it pulls down or wears away, and builds them up anew in other forms. As soon as an ocean washed over the consolidated crust of the globe, it would begin to abrade the surfaces upon which it moved, gradually loosening and detaching materials, to deposit them again as sand or mud or pebbles at its bottom in successive layers, one above another. Thus, in analyzing the crust of the globe, we find at once two kinds of rocks, the respective work of fire and water: the first poured out from the furnaces within, and cooling, as one may see any mass of metal cool that is poured out from a smelting-furnace to-day, in solid crystalline masses, without any division into separate layers or leaves; and the latter in successive beds, one over another, the heavier materials below, the lighter above, or

7,703

sometimes in alternate layers, as special causes may have determined successive deposits of lighter or heavier materials at some given spot.—AGASSIZ *Geological Sketches*, ser. i, ch. 1, p. 5. (H. M. & Co., 1896.)

105. AGENCY, UNCONSCIOUS — *Insects Allured by Nectar Carry Away Adhering Pollen—Narrow Self-seeking Fulfils Wide Design.*—Small insects alight on the labellum of the *Listera ovata* for the sake of the nectar copiously secreted by it; as they lick this they slowly crawl up its narrowed surface until their heads stand directly beneath the overarching crest of the rostellum; when they raise their heads they touch the crest; this then explodes, and the pollinia are instantly and firmly cemented to their heads. As soon as the insect flies away, it withdraws the pollinia, carries them to another flower, and there leaves masses of the friable pollen on the adhesive stigma.—DARWIN *Fertilization of Orchids*, ch. 4. p. 119. (A., 1898.)

106. AGENT LOST IN RESULT—*Heat Disappears in Work.*—We can raise a weight by heat; and in this agent we possess an enormous store of mechanical power. A pound of coal produces by its combination with oxygen an amount of heat which, if mechanically applied, would suffice to raise a weight of 100 pounds to a height of twenty miles above the earth's surface. Conversely, 100 pounds falling from a height of twenty miles, and striking against the earth, would generate an amount of heat equal to that developed by the combustion of a pound of coal. Wherever work is done by heat, heat disappears. A gun which fires a ball is less heated than one which fires blank cartridge. The quantity of heat communicated to the boiler of a working steam-engine is greater than that which could be obtained from the recondensation of the steam, after it had done its work; and the amount of work performed is the exact equivalent of the amount of heat lost.—TYNDALL *Fragments of Science*, vol. i, ch. 16, p. 373. (A., 1897.)

107. AGENT OF DESTRUCTION VANISHES, RUIN REMAINS—*Explosion of Volcano Likened to Bursting of a Boiler.*—We may compare the explosion of a volcano to the action of a bursting boiler, when in a moment the rupturing agent disappears in the air, leaving only the fragments of the vessel which contained it and which it has torn to pieces.—SHALER *Aspects of the Earth*, p. 65. (S., 1900.)

108. AGE OF DEEP-SEA ORGANISMS—*Oldest Genera at Greatest Depths.*—Agassiz points out that all those genera that have the greatest bathymetrical range, extending from the littoral to the abysmal region, are at the same time genera which date back to the cretaceous period, while those having a somewhat more limited range go back to the tertiaries, and those that extend only slightly beyond the littoral area go back only to the later tertiaries.

This interesting generalization brings home to our minds the enormous length of time that it must have taken these animals to migrate from the shallow to the deep sea. In the struggles for existence between marine animals it must always have been the last resort of those unable to compete with the younger generations in shallow water to migrate into the deeps.

The scarcity of food, the darkness, and the pressure of these regions can never be so favorable for the support of animals as the conditions of the shores. We can well imagine that a species would take every opportunity that is afforded to return from such inhospitable habitats, and that only when, as it were, every door is closed, when no island, continent, or cape can afford it a free scope for life in shallow water, does it become a true deep-sea species.—HICKSON *Fauna of the Deep Sea*, ch. 5, p. 103. (A., 1894.)

109. AGE OF SEQUOIAS—*Brevity of Human Life and Fame.*—So far as we can judge from the actual counting of the layers of several trees, no sequoia now alive sensibly antedates the Christian era. . . . That the more remarkable of these trees should bear distinguishing appellations seems proper enough; but the tablets of personal names which are affixed to many of them in the most visited groves—as if the memory of more or less notable people of our day might be made enduring by the juxtaposition—do suggest some incongruity. When we consider that a hand's breadth at the circumference of any one of the venerable trunks so placarded has recorded in annual lines the lifetime of the individual thus associated with it, one may question whether the next hand's breadth may not measure the fame of some of the names thus ticketed for adventitious immortality. Whether it be the man or the tree that is honored in the connection, probably either would live as long, in fact and in memory, without it.—ASA GRAY *Darwiniana*, art. 5, p. 207. (A., 1889.)

110. AGE OF TREES—*Yew, Linden, and Eucalyptus—Relative Brevity of Human Life.*—Decandolle finds that of all European species of trees the yew attains the greatest age; and according to his calculations thirty centuries must be assigned as the age of the *Taxus baccata* of Braburn in Kent, from twenty-five to twenty-six to the Scotch yew of Fortingal, and fourteen and one-half and twelve respectively to those of Crowhurst in Surrey and Ripon (Fountains Abbey) in Yorkshire. Endlicher remarks that "another yew-tree in the churchyard of Grasford, North Wales, which measures more than fifty feet in girth below the branches, is more than 1,400 years old, whilst one in Derbyshire is estimated at

2,096 years. In Lithuania linden trees have been felled which measured eighty-seven feet round, and in which 815 annular rings have been counted." In the temperate zone of the southern hemisphere some species of the eucalyptus attain an enormous girth, and as they at the same time attain a height of nearly 250 feet, they afford a singular contrast to our yew-trees, which are colossal only in thickness. Mr. Backhouse found in Emu Bay, on the shore of Van Diemen's Land, eucalyptus trunks which, with a circumference of seventy feet at the base, measured as much as fifty feet at a little more than five feet from the ground.—HUMBOLDT *Views of Nature*, p. 274. (Bell, 1896.)

111. AGES OF GEOLOGY—*Early Geologists Grasped Essentials.*—Altho subsequent investigations have multiplied extensively the number of geological periods, . . . yet the first general division into three great eras [primary, secondary, and tertiary] was nevertheless founded upon a broad and true generalization. In the first stratified rocks in which any organic remains are found, the highest animals are fishes, and the highest plants are cryptogams; in the middle periods reptiles come in, accompanied by fern and moss forests; in later times quadrupeds are introduced, with a dicotyledonous vegetation. So closely does the march of animal and vegetable life keep pace with the material progress of the world, that we may well consider these three divisions, included under the first general classification of its physical history, as the three ages of nature; the more important epochs which subdivide them may be compared to so many great dynasties, while the lesser periods are the separate reigns contained therein.—AGASSIZ *Geological Sketches*, ser. i, ch. 1, p. 15. (H. M. & Co., 1896.)

112. AGES PRECEDING HUMAN HISTORY—*Momentary Life of Man.*—How these grand contemplations enlarge the ideas which we habitually form of nature! We imagine that we go very far back in the past in contemplating the old pyramids still standing on the plains of Egypt, the obelisks engraved with mysterious hieroglyphics, the silent temples of Assyria, the ancient pagodas of India, the idols of Mexico and Peru, the time-honored traditions of Asia and of the Aryans, our ancestors, the instruments of the stone age, the flint weapons, the arrows, the lances, the knives, the sling-stones of our primitive barbarism—we scarcely dare to speak of ten thousand, of twenty thousand years. But even if we admit a hundred thousand years for the age of our species, so slowly progressive, what is even this compared with the fabulous succession of ages which have preceded us in the history of the planet!—FLAMMARION *Popular Astronomy*, bk. i, ch. 7, p. 77. (A.)

113. AGNOSTIC AGREES WITH SCRIPTURE—*"Neither Can He Know Them" (1 Cor. ii, 14)—No Prohibition, but a Statement of Fact.*—It is no spell of ignorance arbitrarily laid upon certain members of the organic kingdom that prevents them reading the secrets of the spiritual world. It is a scientific necessity. No exposition of the case could be more truly scientific than this: "The natural man receiveth not the things of the spirit of God; for they are foolishness unto him; neither can he know them, because they are spiritually discerned." The verb here, it will be again observed, is potential. This is not a dogma of theology, but a necessity of science. And science, for the most part, has consistently accepted the situation. It has always proclaimed its ignorance of the spiritual world. When Mr. Herbert Spencer affirms, "Regarding science as a gradually increasing sphere we may say that every addition to its surface does not but bring it into wider contact with surrounding nescience," from his standpoint he is quite correct. The endeavors of well-meaning persons to show that the agnostic's position, when he asserts his ignorance of the spiritual world, is only a pretense; the attempts to prove that he really knows a great deal about it, if he would only admit it, are quite misplaced. He really does not know. The verdict that the natural man receiveth not the things of the spirit of God, that they are foolishness unto him, that neither can he know them, is final as a statement of scientific truth—a statement on which the entire agnostic literature is simply one long commentary.—DRUMMOND *Natural Law in the Spiritual World*, int., p. 69. (H. Al.)

114. AGNOSTICISM—*A Witness for Christian Truth.*—The Pauline anthropology has been challenged as an insult to human nature. Culture has opposed the doctrine that "The natural man receiveth not the things of the spirit of God, for they are foolishness unto him: neither can he know them, because they are spiritually discerned" (I Cor. ii, 14). . . . The history of thought during the present century proves that the world has come round spontaneously to the position of the first. One of the ablest philosophical schools of the day erects a whole anti-christian system on this very doctrine. Seeking by means of it to sap the foundation of spiritual religion, it stands unconsciously as the most significant witness for its truth. What is the creed of the agnostic but the confession of the spiritual numbness of humanity? The negative doctrine which it reiterates with such sad persistency, what is it but the echo of the oldest of scientific and religious truths? And what are all these gloomy and rebellious infidelities, these touching and too sincere confessions of universal nescience, but a protest against this ancient law of

death?—DRUMMOND *Natural Law in the Spiritual World*, p. 143. (H. Al.)

115. ——— ——— *Hopelessness of.*—The agnostic evolution thus leaves us as orphans in the midst of a cold and insensate nature. We are no longer dwellers in our Father's house, beautiful and fitted for us, but are thrown into the midst of a hideous conflict of dead forces, in which we must finally perish and be annihilated. In a struggle so hopeless it is a mere mockery to tell us that in millions of years something better may come out of it; for we know that this will be of no avail to us, and we feel that it is impossible. Thus the agnostic philosophy, if it be once accepted as true, seriously raises the question whether life is worth living.—DAWSON *Facts and Fancies in Modern Science*, lect. 1, p. 99. (A. B. P. S.)

116. ——— ——— *Its Hypotheses Need a God.*—An excellent judge, a gifted adept in physical science and exact reasoning, the late Clerk-Maxwell, is reported to have said, not long before he left the world that he had scrutinized all the agnostic hypotheses he knew of, and found that they one and all needed a God to make them workable.—ASA GRAY *Natural Science and Religion*, lect. 2, p. 91. (S., 1891.)

117. AGREEMENT OF INDEPENDENT THINKERS—*Wallace and Darwin Reach the Same Conclusion.*—Such being the general ferment in the minds of naturalists, it is no wonder that they mustered strong in the rooms of the Linnæan Society, on the 1st of July of the year 1858, to hear two papers by authors living on opposite sides of the globe, working out their results independently, and yet professing to have discovered one and the same solution of all the problems connected with species. The one of these authors was an able naturalist, Mr. Wallace, who had been employed for some years in studying the productions of the islands of the Indian Archipelago, and who had forwarded a memoir embodying his views to Mr. Darwin, for communication to the Linnæan Society. On perusing the essay Mr. Darwin was not a little surprised to find that it embodied some of the leading ideas of a great work which he had been preparing for twenty years, and parts of which containing a development of the very same views, had been perused by his private friends fifteen or sixteen years before. Perplexed in what manner to do full justice both to his friend and to himself, Mr. Darwin placed the matter in the hands of Dr. Hooker and Sir Charles Lyell, by whose advice he communicated a brief abstract of his own views to the Linnæan Society, at the same time that Mr. Wallace's paper was read. Of that abstract the work on the "Origin of Species" is an enlargement.—HUXLEY *Lay Sermons*, serm. 12, p. 291. (G. P. P., 1899.)

118. AGREEMENT OF PLANT AND ANIMAL—*Each an Aggregate of Units.*—The substance of our recent knowledge is that a plant is an aggregate of organic units, mostly of very small size; that these are to the herb or tree what the bricks and stones are to the edifice. Only they "are living stones, fitly framed together" in organic growth, and their walls answer to the cement. Animals do not differ materially, except that the mortar is mostly of the same nature as the bricks, and there is a greater or at length complete fusion or confluence of the cells. The component material, the protoplasm, is essentially the same.—ASA GRAY *Natural Science and Religion*, lect. 1, p. 30. (S., 1891.)

119. AGREEMENT OF SUN AND MOON IN APPARENT SIZE—*Dependence of Astronomy on Seeming Accident.*—If the moon had a disk much smaller than the sun's there would never be a total eclipse of the sun, and all those wonderful objects which make their appearance when the sun is totally eclipsed—the colored prominences and the sierra, the glowing inner corona, and the radiated fainter glory which lies outside the corona—would have been altogether unknown to us. But we should scarcely have learned more if the moon had had a disk much larger than the sun's. For in that case, when a total eclipse began all the region round the sun, except that close to the part of the sun's face concealed last, would be hidden by the moon's much larger disk. . . . We now see during totality the complete ring of prominences for two or three minutes, and the whole of the corona is shown. Even as thus shown it has been sufficiently difficult to ascertain the nature of these objects. But with a moon much larger than ours we could have learned scarcely anything respecting them, and with a moon much smaller we should have known absolutely nothing of the solar appendages. —PROCTOR *Expanse of Heaven*, p. 38. (L. G. & Co., 1897.)

120. AGRICULTURE AIDED BY CHEMISTRY—*The Fertilization of Soils.*—Chemical analysis taught the farmer that, to a certain depth, his field contains only a very limited amount of what is required to grow plants, and in what form a fertilizing substance is able to afford nourishment. It showed him also that stable manure, excellent as it is, is not adequate for sustaining the farm's products; that to farm with nothing but stable manure produced upon the farm could not increase the amount of nourishing substances in the soil, but would only set these in motion and displace them; that he could not contribute to the surface of an exhausted grain field what he had just withdrawn from the field beneath by means of the plants for fodder; that he was not giving to any field more than he was taking from it, or otherwise, only at the expense of some other field; that the revenue from a

farm tilled wholly by means of stable manure was like a life-annuity—it was using up his capital.—LIEBIG *Addresse vor der öffentlichen Sitzung der königlichen Akademie der Wissenschaften, Munich, 1861.* (Translated for *Scientific Side-Lights.*)

121. AGRICULTURE AND COMMERCE, PRIMITIVE—*Lake-dwellers of Switzerland.*—The lake-inhabitants of Switzerland cultivated several kinds of wheat and barley, the pea, the poppy for oil and flax; and they possessed several domesticated animals. They also carried on commerce with other nations.—DARWIN *Origin of Species*, ch. 1, p. 16. (Burt.)

122. AGRICULTURE AN EARLY INVENTION—*Beginnings of, among Savages—Purpose, Industry, and Settled Life Required.*—Man, even while he feeds himself as the lower animals do, by gathering wild fruit and catching game and fish, is led by his higher intelligence to more artificial means of getting these. Rising to the next stage, he begins to grow supplies of food for himself. Agriculture is not to be looked on as a difficult or out-of-the-way invention, for the rudest savage, skilled as he is in the habits of the food-plants he gathers, must know well enough that if seeds or roots are put in a proper place in the ground they will grow. Thus it is hardly through ignorance, but rather from roving life, bad climate, or sheer idleness, that so many tribes gather what nature gives, but plant nothing. Even very rude people, when they live on one spot all the year round, and the climate and soil are favorable, mostly plant a little, like the Indians of Brazil, who clear a patch of forest round their huts to grow a supply of maize, cassava, bananas, and cotton.—TYLOR *Anthropology*, ch. 9, p. 214. (A., 1899.)

123. AGRICULTURE, PRIMITIVE, OF NORTH AMERICA—*An Original Product—Maize.*—But American agriculture was not imported from abroad; it resulted from, and in return rendered possible, the gradual development of American semi-civilization. This is proved by the fact that the grains of the Old World were entirely absent, and that American agriculture was founded on the maize, an American plant.—AVEBURY *Prehistoric Times*, ch. 8, p. 264. (A., 1900.)

124. AGRICULTURE, PRIMITIVE, WOMAN'S WORK IN—A company of Cocopa or Mohave or Pima women set forth to a rich and favored spot on the side of a cañon or rocky steep. They are guarded by a sufficient number of men from capture or molestation. Each woman has a little bag of gourd-seed, and when the company reach their destination she proceeds to plant the seeds one by one in a rich cranny or crevice where the roots may have opportunity to hold, the sun may shine in, and the vines with their fruit may swing down as from a trellis. The planters then go home and take no further notice of their vines until they return in the autumn to gather the gourds. This is the testimony of E. Palmer, who spent many years as a collector among the American aborigines. Seed-time and harvest: no preparation of the soil, no tending of the young plants; ingathering, that is all.—MASON *Origins of Invention*, ch. 6, p. 192. (S., 1899.)

125. AGRICULTURE, THE FIRST OF ALL IMPLEMENTS IN—After all has been said about other devices, the digging-stick is the beginning of agricultural implements, the progenitor of the hoe, the spade, the plow. It would be difficult to find a tribe so low down as not to know its use.—MASON *Origins of Invention*, ch. 6, p. 190. (S., 1899.)

126. AGRICULTURE THE FOUNDATION OF CIVILIZATION—All civilization is the outgrowth of strivings which go beyond momentary physical needs; and therefore until agriculture affords a firm foundation for subsistence, until life is by the soil made something more than a struggle for momentary support, the foundations of culture cannot be obtained.—SHALER *Nature and Man in America*, ch. 5, p. 170. (S., 1899.)

127. AIR, EXCLUSION OF, QUENCHES FIRE—*Danger of Flight with Burning Garments—Invisible Food of Combustion.*—The flame of an ordinary lantern or lamp, where a chimney is employed, would not burn more than a few minutes if holes were not provided at the base for the ingress of air. But for the occasional application of the poker, the combustion of a common fire would be maintained with difficulty, or prematurely put an end to, for the oxygen of the air must find free access to the interior of the burning mass, or the chemical decompositions we are about to describe cannot take place. On the same principle the best way of extinguishing fire is to smother it; that is, to cover it closely with something that will effectually cut off the source of its existence. If the clothes of some unfortunate friend should happen to catch fire, the best course to follow is to throw him down and envelop him in a rug, blanket, or anything of a similar kind within reach, when the flames will be immediately extinguished. To run about in search of water or assistance in these cases is simply to give time to the flames to reach a vital part of the body.—LOWE *Nature-Studies*, p. 2. (Hum., 1888.)

128. AIR MADE LIQUID—*A Perfect Refrigerant.*—In many of its chapters the history of invention displays an advance from the roundabout to the direct, as we have seen in the substitution of the steam-turbine for the compound engine. Recent modes of refrigeration offer a like illustration. For some years the plan was to employ a series of chemical compounds, each

with a lower boiling-point than its predecessor in the process, and all troublesome and hazardous in manipulation. A better method has been developed by keeping to simple air from first to last. In the Tripler machine air is first compressed to 65 pounds pressure to the square inch; through a second pump this pressure is exalted to 400 pounds, and with a third pump the pressure is carried to 2,500 pounds. After each compression the air flows through jacketed pipes, where it is cooled by a stream of water. At the third condensation a valve, the secret of whose construction Mr. Tripler keeps to himself, permits part of the compressed air to flow into a pipe surrounding the tube through which the remainder is flowing. This act of expansion severely chills the imprisoned air, which at last discharges itself in liquid form—much as water does from an ordinary city faucet.—ILES *Flame, Electricity, and the Camera,* ch. 6. p. 72. (D. & McC.. 1900.)

129. AIR, MAN'S DEPENDENCE UPON —*Bad Air Cannot Always Be Rejected.*—Solicitude with regard to the hostile influences contained within our mixture of air is gradually becoming greater. We are conscious of the 9,000 liters of air we are daily consuming; we might almost grow disheartened before the avowal that this consumption is something compulsory, uninterrupted; that we cannot refuse spoiled air as we can any doubtful, disgusting article of food; that it is not in our power to wait for hours, or even several minutes, until better air can be furnished. Breathe or die, there can be no haggling.—WERNICH *Ueber gute und schlechte Luft,* lect. A lecture. (Translated for *Scientific Side-Lights.)*

130. AIR, PURIFIED, PUTREFACTION IMPOSSIBLE IN—*Tyndall's Glycerin-coated Cabinet.*—A few years after Pasteur's first work on this subject Tyndall (1868) conceived a precise method of determining the absence or presence of dust particles in the air by passing a beam of sunlight through a glass box before and after its walls had been coated with glycerin. Into the floor of the box were fixed the mouths of flasks of infusion. These were boiled, after which they were allowed to cool, and might then be kept for weeks or months without putrefying or revealing the presence of germ life. Here all the conditions of the infusions were natural, except that in the air above them there was no dust. The sum-total of result arising from all these investigations was to the effect that no spontaneous generation was possible, that the atmosphere contained unseen germs of life, that the smallest of organisms responded to the law of gravitation and adhered to moist surfaces, and that micro-organisms were in some way or other the cause of putrefaction.—NEWMAN *Bacteria,* ch. 1, p. 4. (G. P. P., 1899.)

131. ALCOHOL A POISON—*Destroys the Life That Produced It—Necessary Limit to Strength of Fermented Liquors.*—We shall have to consider a remarkable faculty which some bacteria possess of producing products inimical to their own growth. In some degrée this is true of the yeasts, for when they have set up fermentation in a saccharine fluid there comes a time when the presence of the resulting alcohol is injurious to further action on their part. It has become indeed a poison, and, as we have already mentioned, a necessary condition for the action of a ferment is the absence of poisonous substances. This limit of fermentation is reached when the fermenting fluid contains 13 or 14 per cent. of alcohol. —NEWMAN *Bacteria,* ch. 4, p. 119. (G. P. P., 1899.)

132. ALCOHOL DESTROYS VOLITION —*Confirmed Alcoholism—Power and Responsibility in Early Stages.*—It may be confidently stated as a result of universal experience that our "capacity of willing," that is, of giving a preponderance to the motive on which we elect to act, depends, first, upon our conviction that we really have such a self-determining power, and, secondly, upon our habitual exercise of it. The case, which is unfortunately but too common, of a man who habitually gives way to the desire for alcoholic excitement, and is ruining himself and his family by his self-abandonment, will bring into distinct view the practical bearing of the antagonistic doctrines.

The automatism of his nature (purely physical so far as the bodily craving for alcohol is concerned, but including, in most cases, some play of social instincts) furnishes an aggregate of powerful attractions to the present gratification. On the other side is an aggregate of moral deterrents, which, when the attention is fixed upon them in the absence of the attractive object, have a decided preponderance, so far as the desires are concerned. The slave of intemperance is often ready to cry out, "O wretched man that I am, who shall deliver me from the body of this death?"—and he proves his sincerity by his readiness to take every indirect precaution that does not interfere with his personal liberty. But when the temptation recurs, the force of the attraction is intensified by its actual presence; the direct sensory presentation makes a more vivid impression than the ideal representation of the deterrent motives; and the balance, which previously turned against the indulgence, now preponderates in favor of it. What, then, is it within the power of the ego to do? On the automatist theory, nothing. For not only is he unable to call to his aid any motive which does not spontaneously arise, but he cannot make any alteration in the relative strength of

the motives which are actually present to his consciousness. He says, to himself and to others, "I could not help yielding"; and automatism sanctions the plea. Society may be justified in imposing on him either restraint or punishment, alike for its own security and for his welfare; but no consistent automatist can regard him as an object of the moral reprobation which we instinctively feel for the self-degraded sot; and experience shows that the system of external repression almost invariably loses its potency as a deterrent as soon as the restraining influence is withdrawn.

Now, although I hold it beyond question that a state may be induced by habitual alcoholic indulgence in which the unhappy subject of it loses all power of resistance, I affirm it to be "the normal experience of healthy men" that the ordinary toper has such a power in the earlier stages of his decadence, and that he is justly held culpable for not exerting it.—CARPENTER *Mental Physiology*, pref., p. xxxix. (A., 1900.)

133. ALCOHOL, EFFECT OF—*Cumulative—How Small Doses of Poison Operate.*—Small quantities of poisonous substances, such as alcohol, for instance, may be indulged in for years without apparent injury. But finally the total effect of all these small quantities of poison will suddenly appear, not, perhaps, because of any accumulation of those small doses of the poison in the system, but because of an accumulation of their effects.—STRÜMPELL *in an address before the Naturforscher Versammlung, Nuremberg, 1893.* (Translated for *Scientific Side-Lights.*)

134. ——— ——— *Intoxication Allied to Mania—Results May Be Mental Derangement.*—Alcohol yields us, in its direct effects, the abstract and brief chronicle of the course of mania. At first there is an agreeable excitement, a lively flow of ideas, a revival of old ideas and feelings which seemed to have passed from the mind, a general increase of mental activity—a condition very like that which often precedes an attack of acute mania, when the patient is witty, lively, satirical, makes jokes or rimes, and certainly exhibits a brilliancy of fancy which he is capable of at no other time. Then there follows, in the next stage of its increasing action, as there does in mania, the automatic excitation of ideas which start up and follow one another without order, so that thought and speech are more or less incoherent, while passion is easily excited. After this stage has lasted for a time, in some longer, in others shorter, it passes into one of depression and maudlin melancholy, just as mania sometimes passes into melancholia, or convulsion into paralysis. And the last stage of all is one of stupor and dementia. If the abuse of alcohol be continued for years, it may cause different forms of mental derangement, in each of which the muscular are curiously like the mental symptoms: delirium tremens in one, an acute noisy and destructive mania in another, chronic alcoholism in a third, and a condition of mental weakness with loss of memory and loss of energy in a fourth.—MAUDSLEY *Body and Mind*, lect. 3, p. 91. (A., 1898.)

135. ALCOHOL, EFFECT OF—*Upon Children—Alcoholic Imbecility.*—But the greatest ravage is wrought upon the nervous system of the child by means of alcohol. We now are aware that there is no more certain method of breeding idiots than by the continuous administering of alcohol. Thousands of mothers are systematically poisoning their darlings by means of a substance which renders them stupid, languid, and without energy; and, according to circumstances, makes of them physical and mental cripples. Therefore away with this pernicious faith in the "strengthening" effect of alcohol, away with the "strengthening" wines for chronic conditions of weakness, anemia, and chlorosis; above all let us do away with alcoholic poisons in the nursery, that we may not lead the generation that is now growing up into sickness and degeneration with our own hands.—KRÄPELIN *A Lecture.* (Translated for *Scientific Side-Lights.*)

136. ALCOHOL IN BREAD INCONSIDERABLE—*A Disastrous Experiment.*—Not many years ago £20,000 was lost in the prosecution of a scheme for collecting the alcohol that distils from bread in baking, all which would have been saved to the subscribers had they known that less than a hundredth part by weight of the flour is changed in fermentation.—HERBERT SPENCER *Education*, chap. 1, p. 38. (A., 1900.)

137. ALCOHOL, IS IT A FOOD OR A POISON?—We are thus freed from the dilemma in which we were placed by admitting on the one hand that alcohol has no albumen-saving properties, as has been proven by many experiments, and by claiming for it on the other hand the power to save fat. For the two facts from which these contradictory assumptions have been deduced, namely, the absence of a diminution in the breaking up of albumen and the actually noted diminution in the breaking up of fat, far from being contradictory, are simply the necessary result of the toxic and deleterious action which alcohol exerts upon the protoplasm.

In this statement our final sentence against alcohol is pronounced. For the animal and human organism alcohol is not both a food and a poison, but only a poison, which, like all other poisons, is excitant when taken in small doses, while in larger ones it produces paralysis and death.—KASSOWITZ *Alkohol nährend oder toxisch? A Lecture: Werke*, p. 16. (Translated for *Scientific Side-Lights.*)

138. ALCOHOLISM IN THE FRONT RANK OF DISEASES—*Prevention of Disease Now the Watchword of Physicians—The Etiological Epoch in Medicine.*—The present epoch is rightly termed the etiological in medicine. We physicians now acknowledge that recognition of the causes of disease is one of the highest problems of our investigation, because we have become aware that by this means we pave the way not merely for the cure of disease, but also for the far more important—prevention of disease. But how many causes of disease can be found that for extent and importance are at all comparable to chronic alcohol intoxication? At the most there are two infectious diseases, tuberculosis and syphilis, that can be ranked with alcoholism in these respects. But how much more comprehensible, more manifest, more accessible to research and to medical influence are the effects of this chemical substance exactly known, as compared with the complicated biological influences of the parasite micro-organisms!—STRÜMPELL *Ueber die Alkoholfrage vom ärztlichen Standpunkt.* (Translated for *Scientific Side-Lights.)*

139. ALCOHOL PRODUCES CRIMINAL HEREDITY—*The Ancestry of Paris Prisoners.*—I have stated that the prisons are inhabited by degenerates. I might just as well have said, and with as much right, that they are inhabited by the sons of alcoholics. If, in the case of a criminal, we cannot refer to insanity, or hysteria, or epilepsy in the ancestry, we make inquiries regarding alcohol, and in nine cases out of ten we find that to be the root of the evil.—LAURENT *Les Habitués des Prisons de Paris,* p. 21. (Translated for *Scientific Side-Lights.)*

140. ALCOHOL VS. NUTRITION—*Privation a Cause of Intemperance—The Morality of Cookery.*—An instructive experience of my own will illustrate this. When wandering alone through Norway in 1856, I lost the track in crossing the Kjolen fjeld, struggled on for twenty-three hours without food or rest, and arrived in sorry plight at Lom, a very wild region. After a few hours' rest I pushed on to a still wilder region and still rougher quarters, and continued thus to the great Jostedal table-land, an unbroken glacier of 500 square miles; then descended the Jostedal itself to its opening on the Sogne fjord—five days of extreme hardship with no other food than flatbrod (very coarse oatcake) and bilberries gathered on the way, varied on one occasion with the luxury of two raw turnips. Then I reached a comparatively luxurious station (Ronnei), where ham and eggs and claret were obtainable. The first glass of claret produced an effect that alarmed me—a craving for more and for stronger drink, that was almost irresistible. I finished a bottle of St. Julien, and nothing but a violent effort of will prevented me from then ordering brandy.

I attribute this to the exhaustion consequent upon the excessive work and insufficient, unsavory food of the previous five days; have made many subsequent observations on the victims of alcohol, and have no doubt that overwork and scanty, tasteless food is the primary source of the craving for strong drink that so largely prevails with such deplorable results among the class that is the most exposed to such privation. I do not say that this is the only source of such depraved appetite. It may also be engendered by the opposite extreme of excessive luxurious pandering to general sensuality.

The practical inference suggested by this experience and these observations is, that speech-making, pledge-signing, and blue-ribbon missions can only effect temporary results unless supplemented by satisfying the natural appetite of hungry people by supplies of food that are not only nutritious, but savory and varied. Such food need be no more expensive than that which is commonly eaten by the poorest of Englishmen, but it must be far better cooked.—WILLIAMS *Chemistry of Cookery,* ch. 5, p. 60. (A., 1900.)

141. ALCOHOL WEAKENS VOLITION—*Morbid Physical Craving—Physical Remedies for Drunkenness—Seclusion—Absolute Abstinence.*—It is the physical craving produced by the continued action of the stimulant upon the nutrition of the nervous system which renders the condition of the habitual drunkard one with which it is peculiarly difficult to deal by purely moral means. Vain is it to recall the motives for a better course of conduct to one who is already familiar with them all, but is destitute of the will to act upon them; the seclusion of such persons from the reach of alcoholic liquors, for a sufficient length of time to free the blood from its contamination, to restore the healthful nutrition of the brain, and to enable the recovered mental vigor to be wisely directed, seems to afford the only prospect of reformation; and this cannot be expected to be permanent unless the patient determinately adopts and steadily acts on the resolution to abstain entirely from that which, if again indulged in, will be poison alike to his body and to his mind, and will transmit its pernicious influence to his offspring.—CARPENTER *Mental Physiology,* bk. ii, ch. 17, p. 653. (A., 1900.)

142. ALCOHOL, WHAT IS A HARMLESS DOSE OF?—That for alcohol, as for all other medicinal agents of the same order, there may be a dose the effects of which may pass unperceived—which may not diminish the elasticity of our organs—there can be no doubt. But what is this dose? The determination of it is very difficult; it varies with the individual, with the disposition at

the moment, and with a multitude of indefinable circumstances. It is on the average less than 7½ grams; less, therefore, than the amount of alcohol in half a glass of port, in one-tenth of a liter of *bière d'ale;* very much less, therefore, than the quantity in which alcohol is habitually consumed. As soon as the dose is increased there is abuse, and the occasions for abuse are not wanting. Action appears heavy immediately, and the alcohol leaves traces of its passage in the nervous centers.—BOECK *The Influence of Alcoholic Liquors on Mental Work.* (Translation, *Journal of Inebriety,* Jan., 1901.)

143. ALLEVIATION OF HUMAN MISERY—*Practical Result of Science.*—And thus mankind will have one more admonition that "the people perish for lack of knowledge"; and that the alleviation of the miseries, and the promotion of the welfare of men, must be sought, by those who will not lose their pains, in that diligent, patient, loving study of all the multitudinous aspects of nature, the results of which constitute exact knowledge, or science.—HUXLEY *Lay Sermons,* serm. 15, p. 378. (A., 1895.)

144. ALLIANCE OF SCIENCES—*Astronomy No Longer Isolated—Sciences Merging in Unity of Nature.*—The establishment of the new method of spectrum analysis drew far closer this alliance between celestial and terrestrial science. Indeed, they have come to merge so intimately one into the other that it is no easier to trace their respective boundaries than it is to draw a clear dividing-line between the animal and vegetable kingdoms. Yet up to the middle of the present century astronomy, while maintaining her strict union with mathematics, looked with indifference on the rest of the sciences; it was enough that she possessed the telescope and the calculus. Now the materials for her inductions are supplied by the chemist, the electrician, the inquirer into the most recondite mysteries of light and the molecular constitution of matter. She is concerned with what the geologist, the meteorologist, even the biologist, has to say; she can afford to close her ears to no new truth of the physical order. Her position of lofty isolation has been exchanged for one of community and mutual aid. The astronomer has become, in the highest sense of the term, a physicist, while the physicist is bound to be something of an astronomer.—CLERKE *History of Astronomy,* pt. ii, ch. 1, p. 176. (Bl., 1893.)

145. ALLUREMENT BY IMITATION—*Wingless Mantis Resembles Orchis.*—But the most curious and beautiful case of alluring protection is that of a wingless mantis in India, which is so formed and colored as to resemble a pink orchis or some other fantastic flower. The whole insect is of a bright pink color, the large and oval abdomen looking like the labellum of an orchid. On each side the two posterior legs have immensely dilated and flattened thighs which represent the petals of a flower, while the neck and forelegs imitate the upper sepal and column of an orchid. The insect rests motionless, in this symmetrical attitude, among bright green foliage, being, of course, very conspicuous, but so exactly resembling a flower that butterflies and other insects settle upon it and are instantly captured. It is a living trap, baited in the most alluring manner to catch the unwary flower-haunting insects.—WALLACE *Darwinism,* ch. 8, p. 144. (Hum., 1889.)

146. ALMIGHTY, THE, SUN AN EMBLEM OF—*The Source of All Life on the Earth—Destruction if Sun's Light Withheld—Fiery Death if Sun's Light Intensified.*—The sun is an emblem of the Almighty in being the source whence all that lives upon the earth derives support. Our very existence depends on the beneficent supply of light and heat poured out continually upon the earth by the great central orb of the planetary scheme. Let the sun forget to shine for a single day, and it would be with us even as tho God had forgotten our existence. . . . Myriads of creatures now living on the earth would perish, uncounted millions would suffer fearfully. But let the sun's rays cease to be poured out for four or five days, and every living creature on the earth would be destroyed. Or, on the other hand, even a worse (or at least more sudden and terrible) fate would befall us if an angel of wrath "poured out his vial upon the sun, and power were given unto it to scorch men with fire."—PROCTOR *Expanse of Heaven,* ch. 2, p. 11. (L. G. & Co., 1897.)

147. ALMSHOUSE OF OCEAN—*Ancient Geologic Forms Have Representatives in Deep Sea.*—One of the most striking features connected with the animals of the deep sea is the frequency with which we find there living species which remind us of kinds which in former geologic periods dwelt in the coastal districts of the oceans. It seems that many of these ancient creatures, when they no longer could hold their own against the more highly organized and developed animals which inhabited the favored stations next the shores, shrunk away into the deep water, and in that undesired part of the world found an asylum, where, amid the changeless environment, they have dwelt for ages, unaltered. Thus the vast profounds of the deep have become a sort of almshouse, whereunto antiquated species have retired before the overwhelming pressure which the newer and higher life ever imposes.—SHALER *Sea and Land,* p. 102. (S., 1894.)

148. ALPHABET OF GEOLOGY—*Evidences of the Work of an Ancient Stream.*—On entering it (the gorge of the Via Mala), the first conclusion is that it must be a fissure. This conclusion in my case was

modified as I advanced. Some distance up the gorge I found upon the slopes to my right quantities of rolled stones, evidently rounded by water-action. Still further up, and just before reaching the first bridge which spans the chasm, I found more rolled stones, associated with sand and gravel. Through this mass of detritus, fortunately, a vertical cutting had been made, which exhibited a section showing perfect stratification. There was no agency in the place to roll these stones, and to deposit these alternating layers of sand and pebbles, but the river which now rushes some hundreds of feet below them. At one period of the Via Mala's history the river must have run at this high level. Other evidences of water-action soon revealed themselves.—TYNDALL *Hours of Exercise in the Alps*, ch. 20, p. 220. (A., 1898.) 7,703

149. ALTAR OF STONEHENGE—*A Nameless Ancient Astronomer and His Enduring Memorial—Evidence of Ancient Sun-worship in England.*—The visitor to Salisbury Plain sees around him a lonely waste, utterly barren except for a few recently planted trees, and otherwise as desolate as it could have been when Hengist and Horsa landed in Britain; for its monotony is still unbroken except by the funeral mounds of ancient chiefs, which dot it to its horizon, and contrast strangely with the crowded life and fertile soil which everywhere surround its borders. In the midst of this loneliness rise the rude, enormous monoliths of Stonehenge—circles of gray stones which seem as old as time, and were there, as we now are told, the temple of a people which had already passed away, and whose worship was forgotten when our Saxon forefathers first saw the place.

In the center of the inner circle is a stone which is believed once to have been the altar; while beyond the outmost ring, quite away to the northeast upon the open plain, still stands a solitary stone, set up there evidently with some special object by the same unknown builders. Seen under ordinary circumstances, it is difficult to divine its connection with the others; but we are told that once in each year, upon the morning of the longest day, the level shadow of this distant, isolated stone is projected at sunrise to the very center of the ancient sanctuary, and falls just upon the altar. The primitive man who devised this was both astronomer and priest, for he not only adored the risen god whose first beams brought him light and warmth, but he could mark his place, and tho utterly ignorant of its nature, had evidently learned enough of its motions to embody his simple astronomical knowledge in a record so exact and so enduring that, tho his very memory has gone, common men are still interested in it; for, as I learned when viewing the scene, people are accustomed to come from all the surrounding country and pass in this desolate spot the short night preceding the longest day of the year, to see the shadow touch the altar at the moment of sunrise.—LANGLEY *The New Astronomy*, ch. 1, p. 1. (H. M. & Co., 1896.)

150. ALTRUISM A NECESSITY OF REPRODUCTION—*Only by Maternal Care and Solicitude Do Races Survive—The Vicarious Principle in Nature.*—Sympathy, tenderness, unselfishness, and the long list of virtues which make up altruism, are the direct outcome and essential accompaniment of the reproductive process. Without some rudimentary maternal solicitude for the egg in the humblest forms of life, or for the young among higher forms, the living world would not only suffer, but would cease. For a time in the life-history of every higher animal the direct, personal, gratuitous, unrewarded help of another creature is a condition of existence. Even in the lowliest world of plants the labors of maternity begin, and the animal kingdom closes with the creation of a class in which this function is perfected to its last conceivable expression. The vicarious principle is shot through and through the whole vast web of nature; and if one actor has played a mightier part than another in the drama of the past, it has been self-sacrifice. What more has come into humanity along the line of the struggle for the life of others will be shown later. But it is quite certain that, of all the things that minister to the welfare and good of man, of all that make the world varied and fruitful, of all that make society solid and interesting, of all that make life beautiful and glad and worthy, by far the larger part has reached us through the activities of the struggle for the life of others.—DRUMMOND *Ascent of Man*, p. 18. (J. P., 1900.)

151. AMAZEMENT AT POWER OF MAGNET—*Augustine's Description.*—"When I first saw it," says St. Augustine, speaking of the attraction of the magnet, "I was thunderstruck (*"vehementer inhorrui"*), for I saw an iron ring attracted and suspended by the stone; and then, as if it had communicated its own property to the iron it attracted, and had made it a substance like itself, this ring was put near another and lifted it up, and as the first ring clung to the magnet, so did the second ring to the first. A third and fourth were similarly added, so that there hung from the stone a kind of chain of rings with their hoops connected, not interlinking, but attached together by their outer surface. Who would not be amazed at this virtue of the stone, subsisting, as it does, not only in itself, but transmitted through so many suspended rings and binding them together by invisible links?

"Yet far more astonishing is what I heard about the stone from my brother in the episcopate, Severus, Bishop of Milevis. He told me that Bathanarius, once Count of

Africa, when the bishop was dining with him, produced a magnet, and held it under a silver plate on which he placed a bit of iron; then as he moved his hand, with the magnet underneath the plate, the iron upon the plate moved about accordingly. The intervening silver was not affected at all, but precisely as the magnet was moved backward and forward below it, no matter how quickly, so was the iron attracted above. I have related what I myself have witnessed. I have related what I was told by one whom I trust as I trust my own eyes."—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 4, p. 87. (J. W., 1898.)

152. AMBIGUITY OF THE WORD "LIGHT"—*Natural Agency vs. Human Impression—The Luminiferous Ether.*—The word "light" may be used in two different senses; it may mean the impression made upon consciousness, or it may mean the physical agent which makes the impression. . . . That agent is a substance which fills all space, and surrounds the atoms and molecules of bodies. To this interstellar and interatomic medium definite mechanical properties are ascribed, and we deal with it in our reasonings and calculations as a body possessed of these properties. In mechanics we have the composition and resolution of forces and of motions, extending to the composition and resolution of vibrations. We treat the luminiferous ether on mechanical principles, and, from the composition, resolution, and interference of its vibrations we deduce all the phenomena displayed by crystals in polarized light.—TYNDALL *Lectures on Light*, lect. 4, p. 128. (A., 1898.)

153. AMBITION OF GREAT ASTRONOMER—*Investigation of All Stars in the Heavens.*—"I resolved," he [Herschel] writes, "to examine every star in the heavens with the utmost attention and a very high power, that I might collect such materials for this research as would enable me to fix my observations upon those that would best answer my end. The subject has already proved so extensive, and still promises so rich a harvest to those who are inclined to be diligent in the pursuit, that I cannot help inviting every lover of astronomy to join with me in observations that must inevitably lead to new discoveries."—CLERKE *History of Astronomy*, ch. 1, p. 15. (Bl., 1893.)

154. AMERICA AN UNSTABLE CONTINENT—*Peril of High Buildings—Northern Europe Stable by Comparison.*—It is clear that we cannot, in this country, reckon on an earth as stable as that of the northern region of Europe, where our race was bred and our building system developed. It is equally clear that the mode of construction should be adapted to the new needs which the less firm ground of this country imposes on us. As long as the building material most commonly in use was timber, and the masonry structures of a low and substantial nature, they were fairly fitted to afford the resistance required to withstand the shocks which could be expected to come upon them. But the combination of ambition and economy which is filling the land with lofty and flimsy structures invites calamity on the least disturbance of the earth. The shock of 1755, which did little more than stir the fears, shake down the chimney-tops of the old town of Boston, and afford a text for many interesting sermons, would be extremely disastrous to the higher and weaker structures of to-day.—SHALER *Aspects of the Earth*, p. 39. (S., 1900.)

155. AMERICA THE OLD WORLD—*First to Rise from the Waste of Waters.*—First-born among the continents, tho so much later in culture and civilization than some of more recent birth, America, so far as her physical history is concerned, has been falsely denominated the New World. Hers was the first dry land lifted out of the waters, hers the first shore washed by the ocean that enveloped all the earth beside; and while Europe was represented only by islands rising here and there above the sea, America already stretched an unbroken line of land from Nova Scotia to the Far West. —AGASSIZ *Geological Sketches*, ser. i. ch. 1, p. 1. (H. M. & Co., 1896.)

156. AMUSEMENTS OF ANIMALS—*Wild Vaulting of Ibis in the Air.*—The black-faced ibis of Patagonia, a bird nearly as large as a turkey, indulges in a curious mad performance, usually in the evening, when feeding-time is over. The birds of a flock, while winging their way to the roosting-place, all at once seem possessed with frenzy, simultaneously dashing downwards with amazing violence, doubling about in the most eccentric manner; and when close to the surface rising again to repeat the action, all the while making the air palpitate for miles around with their hard, metallic cries. Other ibises, also birds of other genera, have similar aerial performances.—HUDSON *Naturalist in La Plata*, ch. 19, p. 265. (C. & H., 1895.)

157. ANALOGY OF NATURAL AND SPIRITUAL—*Poetry a Form of Science.*—How profoundly Hebrew poetry is saturated with this high thought will appear when we try to conceive of it with this left out. True poetry is only science in another form. And long before it was possible for religion to give scientific expression to its greatest truths, men of insight uttered themselves in psalms which could not have been truer to nature had the most modern light controlled the inspiration. "As the hart panteth after the water-brooks, so panteth my soul after Thee, O God!" What fine sense of the analogy of the natural and the spiritual does not underlie these words! As the hart after its environment, so man after his; as the

water-brooks are fitly designed to meet the natural wants, so fitly does God implement the spiritual need of man. It will be noticed that in the Hebrew poets the longing for God never strikes one as morbid, or unnatural to the men who uttered it. It is as natural to them to long for God as for the swallow to seek her nest. Throughout all their images no suspicion rises within us that they are exaggerating. We feel how truly they are reading themselves, their deepest selves. No false note occurs in all their aspiration.—DRUMMOND *Natural Law in the Spiritual World*, p. 245. (H. Al.)

158. ANALOGY OF VEGETATION OF OLD AND NEW WORLDS—*Unity of Nature.*—Amid the colossal and majestic forms of an exotic flora we feel how wonderfully the flexibility of our nature fits us to receive new impressions, linked together by a certain secret analogy. We so readily perceive the affinity existing among all the forms of organic life that, altho the sight of a vegetation similar to that of our native country might at first be most welcome to the eye, as the sweet familiar sounds of our mother tongue are to the ear, we nevertheless, by degrees, and almost imperceptibly, became familiarized with a new home and a new climate. As a true citizen of the world, man everywhere habituates himself to that which surrounds him; yet fearful, as it were, of breaking the links of association that bind him to the home of his childhood, the colonist applies to some few plants in a far-distant clime the names he had been familiar with in his native land; and by the mysterious relations existing among all types of organization, the forms of exotic vegetation present themselves to his mind as nobler and more perfect developments of those he had loved in earlier days. Thus do the spontaneous impressions of the untutored mind lead, like the laborious deductions of cultivated intellect, to the same intimate persuasion that one sole and indissoluble chain binds together all nature.—HUMBOLDT *Cosmos*, vol. i, int., p. 27. (H., 1897.)

159. ANALYSIS A COMPLEX PROBLEM—*An Expert Alone Can Secure Needed Data—Must Know "Gathering-ground" of Water.*—Accompanying the sample [of water] should be a more or less full statement of its source. There can be no doubt that, in addition to a chemical and bacteriological report of a water, there should also be made a careful examination of its source. This may appear to take the bacteriologist far afield, and in point of fact, as regards distance, this may be so. But until he has seen for himself what "the gathering-ground" is like, and from what sources come the feeding streams, he cannot judge the water as fairly as he should be able to do. The configuration of the gathering-ground, its subsoil, its geology, its rainfall, its relation to the slopes which it drains, the nature of its surface, the course of its feeders, and the absence or presence of cultivated areas, of roads, of houses, of farms, of human traffic, of cattle and sheep—all these points must be noted, and their influence, direct or indirect, upon the water carefully borne in mind.—NEWMAN *Bacteria*, ch. 2, p. 38. (G. P. P., 1899.)

160. ANATOMY AMONG SAVAGES—*Comparative Study of the Toes of the Ostrich.*—The science of homologies, as developed by Cuvier and Hunter and Owen and Huxley, is indeed an intricate, almost a transcendental, science. Yet Dr. Livingstone found the natives of Africa debating a question which belongs essentially to that science and involves the whole principle of the mental process by which it is pursued. The debate was on the question "whether the two toes of the ostrich represent the thumb and forefinger in man, or the little and ring-finger." This is purely a question of comparative anatomy. It is founded on the instinctive perception that even between two frames so widely separated as those of an ostrich and a man there is a common plan of structure, with reference to which plan parts wholly dissimilar in appearance and in use can nevertheless be identified as "representative" of each other—that is, as holding the same relative place in one ideal order of arrangement.—ARGYLL *Reign of Law*, ch. 4, p. 118. (Burt.)

161. ———— ———— *Practical Knowledge of.*—A moment's reflection will show that all savages had a practical knowledge of anatomy. They knew where to strike with the club to paralyze the brain, to slash with the cutlass for the shallow arteries, to pierce with the spear to reach the fountain of life.—MASON *Origins of Invention*, ch. 8, p. 267. (S., 1899.)

162. ANATOMY, COMPARATIVE GIVES FULLER KNOWLEDGE OF MAN—*Likeness and Unlikeness of Lower Animals to Man.*—Comparative anatomy and physiology, by treating the human species as one member of a long series of related organisms, have gained a higher and more perfect understanding of man himself and his place in the universe than could have been gained by the narrower investigation of his species by and for itself. . . . No doubt the phenomena of intellect appear in vastly higher and more complete organization in man than in beings below him in the scale of nature, that beasts and birds only attain to language in its lower rudiments, and that only the germs of moral tendency and social law are discernible among the lower animals. Yet tho the mental and moral interval between man and the nearest animals may be vast, the break is not absolute, and the investigation of the laws of reason and instinct throughout the zoological system, which is already casting some scattered rays of light on the study of man's highest

organization, may be destined henceforth to throw brighter illumination into its very recesses.—DANIEL WILSON *Anthropology*, ch. 1, p. 1. (Hum., 1885.)

163. ANIMALS, ARCTIC—*Commonly White—The Tree-frequenting Sable Is Brown—Raven Needs No Protective Color.*—Whenever we find arctic animals which, from whatever cause, do not require protection by the white color, then neither the cold nor the snow-glare has any effect upon their coloration. The sable retains its rich brown fur throughout the Siberian winter; but it frequents trees at that season and not only feeds partially on fruits or seeds, but is able to catch birds among the branches of the fir-trees, with the bark of which its color assimilates. Then we have that thoroughly arctic animal, the musk-sheep, which is brown and conspicuous; but this animal is gregarious, and its safety depends upon its association in small herds. It is therefore of more importance for it to be able to recognize its kind at a distance than to be concealed from its enemies. . . . The common raven, a true arctic bird, . . . always retains its black coat. . . . The raven is a powerful bird and fears no enemy, while, being a carrion-feeder, it has no need for concealment in order to approach its prey.—WALLACE *Darwinism*, ch. 8, p. 130. (Hum.)

164. — ——— *Once Dwelt in Southern Europe—A Colder Climate in Geologic Times—Reindeer at Foot of Pyrenees.*—The northernmost part of Norway and Sweden is at this day the southern limit of the reindeer in Europe, but their fossil remains are found in large quantities in the drift about the neighborhood of Paris, and quite recently they have been traced even to the foot of the Pyrenees, where their presence would, of course, indicate a climate similar to the one now prevailing in northern Scandinavia. Side by side with the remains of the reindeer are found those of the European marmot, whose present home is in the mountains, about six thousand feet above the level of the sea. The occurrence of these animals in the superficial deposits of the plains of central Europe, one of which is now confined to the high north, and the other to mountain-heights, certainly indicates an entire change of climatic conditions since the time of their existence.—AGASSIZ *Geological Sketches*, ser. i, ch. 8, p. 210. (H. M. & Co., 1896.)

165. ANIMALS AS DISTRIBUTERS OF SEEDS—*Hooks and Spines for Seed-dispersal.*—An idea of the important part played by these various hooks and spines in the dissemination of seeds may be gained by reading the following paragraph written by the German botanist Kerner:

"About ten per cent. of all the flowering plants possess fruits and seeds which are dispersed by means of clawed or barbed processes. The part of the plant which is provided with these structures hooks on to the hairs, bristles, or feathers of any bird or other animal that happens to come into contact with it. The consequence is that it is torn away and carried off by the animal. This act of depredation is, of course, not intentional on the part of the creature that performs it; on the contrary, such appendages are a source of discomfort, and are got rid of as soon as possible. But in many cases this is not accomplished until a considerable distance has been traversed.—WEED *Seed-travelers*, pt. iii, p. 51. (G. & Co., 1899.)

166. ANIMALS, EXISTENCE OF, DEPENDENT ON PLANTS—*The Plant the Mediator between Animal and Mineral.*—The very existence of animal life, to take another case of broad economy, is possible only through the mediation of the plant. No animal has the power to satisfy one single impulse of hunger without the cooperation of the vegetable world. It is one of the mysteries of organic chemistry that the chlorophyll contained in the green parts of plants, alone among substances, has the power to break up the mineral kingdom and utilize the products as food. Tho detected recently in the tissues of two of the very lowest animals, chlorophyll is the peculiar possession of the vegetable kingdom, and forms the solitary point of contact between man and all higher animals and their supply of food. Every grain of matter, therefore, eaten by man, every movement of the body, every stroke of work done by muscle or brain, depends upon the contribution of a plant, or of an animal which has eaten a plant.—DRUMMOND *Ascent of Man*, p. 240. (J. P., 1900.)

167. ANIMALS FIXED TO THE EARTH LIKE PLANTS—*Sponges Rooted to the Sea-floor.*—[There is one division that consists of] animals that remain perfectly fixed to the bottom or are capable only of creeping or crawling over the rocks and sand, such as the sponges, hydroids, sedentary tunicates, gasteropods, most lamellibranchs, and many crustacea. This portion of the fauna [of the sea] has been called the benthos.—HICKSON *Fauna of the Deep Sea*, ch. 3, p. 53. (A., 1894.)

168. ANIMALS GIVE WARNING OF EARTHQUAKE—*Alarm of Dogs, Cats, and Horses—Sea-birds Flying Inland.*—A study of the warnings furnished by animals is also interesting. It is said that several of the natives in Caracas possess oracular quadrupeds, such as dogs, cats, and jerboas, which anticipate coming dangers by their restlessness. Before the catastrophe of 1812, at Caracas, a Spanish stallion broke out from its stable and escaped to the highlands, which was regarded as the result of the prescience of a coming calamity. Before the disturbances of 1822 and 1835, which

shook Chile, immense flocks of sea-birds flew inland, as if they had been alarmed by the commencement of some suboceanic disturbance. Before this last shock it is also related that all the dogs escaped from the city of Talcahuano.—MILNE *Earthquakes*, ch. 18, p. 307. (A., 1899.)

169. ANIMALS, LIMITED INTELLIGENCE OF—*Inability To Learn by Experience—Mingled Folly and Wisdom of Serpent.*—Fabre states (*Souvenirs Entomologiques*, pp. 168-177) that a sphex—an insect belonging to the same highly endowed order with ants—stocks its nest with paralyzed grasshoppers, which are invariably dragged into the burrow by their antennæ. When these were cut off close to the head, the sphex seized the palpi; but when these were likewise cut off, the attempt to drag its prey into the burrow was given up in despair. The sphex had not intelligence enough to seize one of the six legs or the ovipositor of the grasshopper, which, as M. Fabre remarks, would have served equally well. So again, if the paralyzed prey with an egg attached to it be taken out of the cell, the sphex, after entering and finding the cell empty, nevertheless closes it up in the usual elaborate manner. Bees will try to escape and go on buzzing for hours on a window, one-half of which has been left open. Even a pike continued during three months to dash and bruise itself against the glass sides of an aquarium, in the vain attempt to seize minnows on the opposite side. A cobra-snake was seen by Mr. Larard to act much more wisely than either the pike or the sphex; it had swallowed a toad lying within a hole, and could not withdraw its head; the toad was disgorged, and began to crawl away; it was again swallowed and again disgorged; and now the snake had learned by experience, for it seized the toad by one of its legs and drew it out of the hole. The instincts of even the higher animals are often followed in a senseless or purposeless manner: the weaver-bird will perseveringly wind threads through the bars of its cage, as if building a nest; a squirrel will pat nuts on a wooden floor, as if he had just buried them in the ground; a beaver will cut up logs of wood and drag them about, tho there is no water to dam up; and so in many other cases.—DARWIN *Formation of Vegetable Mold*, ch. 2, p. 26. (Hum., 1887.)

170. ANIMALS MAKE CLEARING AROUND THEIR HOMES—*A Resource for Pastime and Protection.*—He [the viscacha] lives in a small community of twenty or thirty members, in a village of deep-chambered burrows, all with their pit-like entrances closely grouped together; and as the village endures forever, or for an indefinite time, the earth constantly being brought up forms a mound thirty or forty feet in diameter; and this protects the habitation from floods on low or level ground. Again, he is not swift of foot, and all rapacious beasts are his enemies; he also loves to feed on tender succulent herbs and grasses, to seek for which he would have to go far afield among the giant grass, where his watchful foes are lying in wait to seize him; he saves himself from this danger by making a clearing all round his abode, on which a smooth turf is formed; and here the animals feed and have their evening pastimes in comparative security: for when an enemy approaches, he is easily seen; the note of alarm is sounded, and the whole company scuttles away to their refuge.—HUDSON *Naturalist in La Plata*, ch. 1, p. 10. (C. & H., 1895.)

171. ——— ——— *Enemies Cannot Approach Unseen—Open Space for Playground.*—The strongest instinct of this animal [the viscacha] is to clear the ground thoroughly about its burrows; and it is this destructive habit that makes it necessary for cultivators of the soil to destroy all the viscachas in or near their fields. On the uninhabited pampas, where the long grasses grow, I have often admired the viscachera; for it is there the center of a clean space, often of half an acre in extent, on which there is an even, close-shaven turf; this clearing is surrounded by the usual rough growth of herbs and giant grasses. In such situations this habit of clearing the ground is eminently advantageous to them, as it affords them a comparatively safe spot to feed and disport themselves on, and over which they can fly to their burrows without meeting any obstruction on the slightest alarm.—HUDSON *Naturalist in La Plata*, ch. 20, p. 303. (C. & H., 1895.)

172. ANIMALS, MARINE, THEIR MODES OF LIFE—Now, amongst marine animals we can recognize three principal modes of life. Some animals simply float or drift about with the currents of the sea and are unable to determine for themselves, excepting, perhaps, within very small limits, the direction in which they travel. Such are the countless forms of protozoa, the jellyfishes and medusæ, numerous pelagic worms and crustacea, . . . and many other forms well known to those who are in the habit of using the tow-net.—HICKSON *Fauna of the Deep Sea*, ch. 3, p. 52. (A., 1894.)

173. ANIMALS NOT AUTOMATA—*Protozoa Show Voluntary Movement.*—There is not the slightest confirmation to be found for the assertion that the lower animals, and children in the early days of life, are merely reflex machines, which make certain movements with mechanical certainty as soon as we press the spring. Even such of the protozoa as undoubtedly belong to the animal kingdom give plain evidence of voluntary movement. The chick just out of the shell executes movements which are in great part at least of the nature of vol-

untary actions. No one will, of course, deny that reflex movements may also be observed from the first, especially among the more complexly organized animals. It must not, however, be forgotten that these purposive reflexes have become possible through an organization acquired in the course of countless generations.—WUNDT *Psychology*, lect. 15, p. 226. (Son. & Co., 1896.)

174. ANIMALS NOT UNDERSTOOD WITHOUT STUDY OF ENVIRONMENT— The fact is, no animal can be correctly appreciated by us if we do not well understand the circumstances of its being, its surrounding conditions. Each creature's structure is an expression and manifestation of that interplay of influences and activities between its own being and its environment, which constitutes its life.—MIVART *Types of Animal Life*, ch. 9, p. 248. (L. B. & Co., 1893.)

175. ANIMALS OF ANCIENT EGYPT SAME AS MODERN—*Five Thousand Years Have Made No Change.*—Our domestic animals have always followed man in the progress of civilization. Wherever the traces of civilization are found, there are found also traces of the presence of animals not only domesticated, but also wild. No civilization has left us more interesting traces in this respect than that of Egypt; on the Egyptian monuments are represented in sculptures and drawings, and in the catacombs are preserved in the shape of mummies, animals which lived many thousand years ago. Some of those relics, which have come down to us, are unquestionably nearly five thousand years old. They form a very interesting basis by which to ascertain to what extent animals may change under the different circumstances in which they live. The most careful comparison which has been made between the skeletons of the animals preserved in mummies, and those recently killed in the valley of the Nile, has not shown the slightest difference between them.—AGASSIZ *Structure of Animal Life*, lect. 3, p. 48. (S., 1886.)

176. ANIMALS, PERFECTION OF— *Enforced by the Death Penalty—Nothing That Lives Can Be Wholly a Failure—All in the Long Run Advancing—Natural Selection.*—By placing the death penalty upon the slightest shortcoming, natural selection so discourages imperfection as practically to eliminate it from the world. The fact that any given animal is alive at all is almost a token of its perfectness. Nothing living can be wholly a failure; for the moment that it fails, it ceases to live. Something more fit, were it even by a hairbreadth, secures its place; so that all existing lives must, with reference to their environment, be the best possible lives. Natural selection is the means employed in nature to bring about perfect health, perfect wholeness, perfect adaptation, and in the long run the ascent of all living things.—DRUMMOND *Ascent of Man*, p. 208. (J. P., 1900.)

177. ANIMALS, PRIMEVAL, DID NOT NEED MOTHERS—*Not Children, but Mere Offspring—The Early World Bleak and Loveless.*—The truth is, Nature so made animals in the early days that they did not need mothers. The moment they were born they looked after themselves, and were perfectly able to look after themselves. Mothers in these days would have been a superfluity. All that Nature worked at at that dawning date was maternity in a physical sense—motherhood came as a later and a rarer growth. The children of those days were not really children at all; they were only offspring, springers off, deserters from home. At one bound they were out into life on their own account, and she who begat them knew them no more. That early world, therefore, for millions and millions of years was a bleak and loveless world. It was a world without children and a world without mothers. It is good to realize how heartless Nature was till these arrived.—DRUMMOND *Ascent of Man*, p. 270. (J. P., 1900.)

178. ANIMALS, PROTECTION OF, BY NON-CONDUCTING CLOTHING—*Utility of Woolen Garments.*—It is the imperfect conductivity of woolen textures which renders them so eminently fit for clothing. They preserve the body from sudden accessions and from sudden losses of heat. The same quality of non-conductivity manifests itself when we wrap flannel round a block of ice. The ice thus preserved is not easily melted. In the case of the human body, on a cold day, the woolen clothing prevents the transmission of motion from within outwards. In the case of the ice, on a warm day, the selfsame fabric prevents the transmission of motion from without inwards. Animals which inhabit cold climates are furnished by nature with their necessary clothing. Birds especially need this protection, for they are still more warm-blooded than the mammalia. They are furnished with feathers, and between the feathers the interstices are filled with down, the molecular constitution and mechanical texture of which render it, perhaps, the worst of all conductors. Here we have another example of that harmonious relation of life to the conditions of life which is incessantly presented to the student of natural science. —TYNDALL *Heat a Mode of Motion*, lect. 9, p. 256. (A., 1900.)

179. ANIMALS, SURRENDER OF, TO MAN—*Submission of Dog, Sheep, and Goat, Llama, Camel, Horse, Ass, Elephant, and Cow.*—By and by they turned the artillery of nature on herself. The dog raised a flag of truce and came in to join the hosts of man against the rest. The mountain-sheep and the wild goat descended from their rocky fortresses, gave up the contest, and surrendered skins and fleece and flesh and milk

to clothe and feed the inventor of the fatal arrow.

Tired of deadly weapons and decoys and snares and pitfalls set by the most cunning of enemies too long ago for any historian, the llama, the camel, the horse, the ass, the elephant, the cow entered into a solemn and everlasting treaty to lend their agile feet, their patient backs and necks and shoulders, their milk, their flesh, their hides, their hair, their very bones, to minister to men's wants. How well this treaty has been observed on both sides let all domestic creatures bear witness. Those that refused to enter in any way into these stipulations are doomed sooner or later to extinction, and many species have already disappeared or withdrawn to the waste places of the earth in despair.—Mason *Origins of Invention*, ch. 8, p. 259. (S., 1899.)

180. ANIMALS TRANSPORTING SEEDS—*The Bur-marigold—The "Sticktights"—Man Limits the Processes of Nature.*—Look at one of these seeds [of the bur-marigold] through a simple lens, and study its structure. See the four ribs extending up and down along the sides, and notice particularly the sharp-pointed hooks curving backward toward the base. See how these ribs project up beyond the seed, as spines provided with recurved barbs.

In pulling the seed-head to pieces, some of these seeds are likely to adhere to the fingers by means of these barbs, while if you touch them to a piece of cloth they *will "stick tight"*—a fact which has given them this term for a common name. It is easy to see how this sort of an adaptation would be useful to the plant in getting its seed dispersed. Instead of calling upon the wind to waft its seeds far and wide, it makes the beasts of the field its burden-bearers. These "stick-tights" will take firm hold upon the hair or fur of almost any of the larger animals, many of which under the conditions existing in previous ages of the world, when our plants were developing, roamed about in just the situations where the bur-marigold is most at home. So, also, they do to-day, tho mankind has interfered in the older settled regions to render communication by such animals between regions far apart more difficult than formerly.—Weed *Seed-travelers*, pt. iii, p. 45. (G. & Co., 1899.)

181. ANIMALS WITHOUT INFANCY—*Parent and Child Never Know Each Other.*—This abnormal form [the *talegallus*—the best known brush-turkey] buries its eggs in the huge mound made by the male, and troubles herself no more about them. When the young is fully developed it simply kicks the coffin to pieces in which its mother interred it, and, burrowing its way up to the sunshine, enters on the pleasures and pains of an independent existence from earliest infancy—that is, if a species born into the world in full possession of all the wisdom of the ancients can be said ever to know infancy.—Hudson *Naturalist in La Plata*, ch. 5, p. 87. (C. & H., 1895.)

182. ANOMALIES OF SCIENCE—*Explanation of Discrepancies Will Reveal New Laws.*—The man of science, like the man of law, has brought before him many an anomaly; but, unlike the judge or the advocate, he knows that the contradictions he studies are only such in seeming; he feels confident that nature at the core is in agreement with herself. Any day, he believes, these apparent contradictions may be resolved into cases of detected law, not simple enough to disclose itself to aught but the most rigorous analysis. In the realm of heat it seems that certain rules of radiation, conduction, boiling-points, and the like, are general, not universal. In most cases they act as if alone; in a few cases their effect is masked by causes as yet not understood. Let a few cases as perplexing as that of the alloys under refrigeration be recounted: Common solder has a lower melting-point than any of its ingredients. Sulfur fuses at 120° C., and thickens again at 220° C. When steel is heated and dipped into cold water it is hardened; the same treatment softens copper. While almost every substance expands with heat, rubber shrinks. In most cases electrical conductivity is impaired by increase of temperature, yet a carbon pencil rises to an almost threefold augmentation of conductivity when brought to incandescence in an electric lamp. We may be well assured that when these anomalies are resolved the explanations will bear in their train other difficulties for research yet more subtile. Science never does worthier work than where, as here, she points to her own unfinished walls, and bids the student as a privilege and a duty to supply their gaps as best he may.—Iles *Flame, Electricity, and the Camera*, ch. 6, p. 76. (D. & McC., 1900.)

183. ANTAGONISMS OF BACTERIA—*Environment That Is Favorable to Some, Destructive of Others.*—Study of the life-history of many of the water bacteria will reveal the fact that they can live and multiply under conditions which would at once prove fatal to other species. Some of these water organisms can indeed increase and multiply in distilled water, whereas it is known that other species cannot even live in distilled water, owing to the lack of pabulum. Thus we see that what is favorable for one species may be the reverse for another.—Newman *Bacteria*, ch. 1, p. 33. (G. P. P., 1899.)

184. ANTHROPOMORPHISM A MISNOMER—*Likeness of Soul, Not of Form.*—The word [anthropomorphism] is in itself a misrepresentation of the fundamental idea which it is employed to designate, and against which it is intended to raise a prejudice. Anthropomorphism means literally

man-formism, conveying the idea that it is, in some sense or other, the human "form" that is ascribed to the agencies which are at work in nature. But this suggestion is altogether at variance with the truth. It is not the form of man that is in question. It is the mind and spirit of man—his reason, his intelligence, and his will. Nor is it even these under all the conditions, or under any of the limitations, with which they are associated in us. But the question is of a real and fundamental analogy, despite all differences of form or of limiting conditions, between the mind which is in us and the mind which is in nature. The true etymological expression for this idea, if we are to have any word constructed on the same model out of Greek, would be. not anthropomorphism, but anthropopsychism, which means not man-formism, but man-soulism. The use of the word in this construction would raise much more truly the real issue.—ARGYLL *Unity of Nature*, ch. 5, p. 99. (Burt.)

185. ANTHROPOMORPHISM AN IDLE BUGBEAR—*All Knowledge Is Anthropomorphic—Man Can Think Only as Man.*—There is indeed one objection to this [teleological] method of conception, which would be a fatal objection if it could be consistently maintained. But all the strength of this objection lies in the obscure terrors which a very long word is sometimes capable of inspiring. This word is "anthropomorphism." Purpose and design, it is said, is a human conception. Unquestionably it is, and so is all knowledge in every form. We can never stand outside ourselves. We can never get behind or above our own methods of conception. The human mind can know nothing and can think of nothing except in terms of its own capacities of thought.—ARGYLL *Reign of Law*, ch. 2, p. 63. (Burt.)

186. ANTHROPOMORPHISM INVERTED—Just as the theologians tell us—and logically enough—that if there is a divine mind, the best, and indeed only, conception we can form of it is that which is formed on the analogy, however imperfect, supplied by the human mind; so with "inverted anthropomorphism" we must apply a similar consideration with a similar conclusion to the animal mind. The mental states of an insect may be widely different from those of a man, and yet most probably the nearest conception that we can form of their true nature is that which we form by assimilating them to the pattern of the only mental states with which we are actually acquainted.—ROMANES *Animal Intelligence*, int., p. 10. (A., 1899.)

187. ANTICIPATIONS OF MODERN METHODS—*Granaries, Original, of Primitive Peoples.*—The thousand and one manipulations at the hands of women formerly practised on vegetal substances preparatory to consumption were all anticipatory of methods now in operation on a grander scale. They were the predecessors of harvesters, wagons and freight trains, granaries and elevators, mills and bakeries. The little wicker basket, holding about a barrel, set up in some northern California hut to preserve acorns, the larger granaries in the Mojave country, the pretty structures conspicuous in the pictures of African villages, are all familiar now on the farm and in the great grain elevators.—MASON *Woman's Share in Primitive Culture*, ch. 2, p. 17. (A., 1894.)

188. ANTICS OF THE SCISSORS-TAIL—*Fun-loving Birds.*—The performance of the scissors-tail, a tyrant-bird, is remarkable. This species is gray and white, with black head and tail and a crocus-yellow crest. On the wing it looks like a large swallow, but with the two outer tail-feathers a foot long. The scissors-tails always live in pairs, but at sunset several pairs assemble, the birds calling excitedly to each other; they then mount upwards, like rockets, to a great height in the air, and, after wheeling about for a few moments, precipitate themselves downwards with amazing violence in a wild zigzag, opening and shutting the long tail-feathers like a pair of shears, and producing loud whirring sounds, as of clocks being wound rapidly up, with a slight pause after each turn of the key. This aerial dance over, they alight in separate couples on the tree-tops, each couple joining in a kind of duet of rapidly repeated, castanet-like sounds.—HUDSON *Naturalist in La Plata*, ch. 19, p. 271. (C. & H., 1895.)

189. ANTIQUITY NOT BARBARISM—The remarkable phase of archaic culture known as Mycenæan [since its remains were first recognized at the ancient Greek city of Mycenæ]—when arms of bronze were beautifully inlaid with gold, when gems were cut, and the potter's art had attained a high degree of perfection—appears to have attained its zenith about 1500 B. C. It must therefore have commenced much earlier.—AVEBURY *Prehistoric Times*, ch. 1, p. 8. (A., 1900.)

190. ANTIQUITY OF ANIMAL ARCHITECTURE—*Beaver-dam a Thousand Years Old—A Geological Survival.*—In one case Prof. Agassiz obtained what may be termed geological evidence of the truth of an opinion advanced by Mr. Morgan, that beaver-works may be hundreds if not thousands of years in course of continuous formation. For the purpose of obtaining a secure foundation for a mill-dam erected above a beaver-dam, it was necessary to clear away the soil from the bottom of the beaver-pond. This soil was found to be a peat-bog. A trench was dug into the peat 12 feet wide by 1,200 feet long, and 9 feet deep: all the way along this trench old stumps of trees were found at various depths, some still

bearing marks of having been gnawed by beavers' teeth. Agassiz calculated the growth of the bog as about a foot per century, so that here we have tolerably accurate evidence of an existing beaver-dam being somewhere about a thousand years old. —ROMANES *Animal Intelligence*, ch. 12, p. 384. (A., 1899.)

191. ANTIQUITY OF ASTRONOMY—*The Most Ancient of the Sciences—Primitive Observations—Egyptian Calendar—Chinese Calendar—The Week Instituted 4,000 Years Ago—Ancient Record of Solar Eclipse.*—Astronomy is the most ancient of the sciences. Even before the invention of writing and the beginning of history men examined the sky and laid the foundations of a primeval almanac. The primitive observations have been lost in the revolutions of nations; we possess, however, some fairly good records, considering their antiquity, among others those of the Egyptians and Chinese made in the thirtieth century before our era, stating that at the vernal equinox the sun was situated in the constellation Taurus, then the first sign of the Zodiac; that of an eclipse of the sun made in Egypt in the year 2720 B. C.; that of a conjunction of the planets in Capricorn, made by the Chinese astronomers in the year 2449 B. C.; that of a star in the constellation Hydra made in the year 2306 B. C. The Egyptian calendar was instituted about the year 2782 B. C., and the Chinese calendar about the year 2637 B. C. At least four thousand years have elapsed since our week of seven days was formed in the plains of Babylon, and for several thousand years also each day has taken the name of one of the moving stars known to the ancients: the Sun, the Moon, Mars, Mercury, Jupiter, Venus, and Saturn.—FLAMMARION *Popular Astronomy*, bk. i, ch. 1, p. 5. (A.)

192. ANTIQUITY OF CHINESE HISTORY IN DOUBT—*Chinese Invention of Compass a Question.*—While the beginning of Chinese history is placed by De Lacouperie at the twenty-third century B. C., other Chinese annalists regard it as impossible to rely upon any records dating back more than 800 years before our era. Legge fixes the beginning of trustworthy chronology at 826 B. C., and Plath at 841 B. C. It is apparent, therefore, that in dealing with the legends and traditions which form the basis for the assertion of knowledge of the magnet by the Chinese at very ancient epochs, the doubt whether they properly belong to mythology or to history is unavoidable.—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 3, p. 66. (J. W., 1898.)

193. ANTIQUITY OF LIFE ON EARTH—*Not Eternal—Geology Proves a Definite Beginning (Gen. i, 1).*—The unstratified rocks are the oldest. They contain no traces of the remains of either animals or plants, and therefore furnish evidence that there was a time when the earth was not inhabited; for there are hardly any animals so soft that none of their parts could be preserved. The solid parts of animals, when once deposited in sand or mud and covered, are there preserved and treasured up for all future time in the solid rock that is formed out of the deposit. In exploring the strata of our earth and examining their contents, geologists have become acquainted with the various animals and plants that have inhabited our globe in the early periods; and their number is so great that the conclusion is inevitable that at all times, since the stratified rocks have been forming, the earth has teemed with inhabitants as various and diversified as they are now. Within the limits of this State there are beds of rock so full of remains of animals and plants that the mass of strata consists of almost nothing else. Indeed, along our seashores we do not find such quantities of dead shells as we find in some of the limestone rocks in the western part of the State of New York. And yet these rocks are among the oldest of the stratified beds on the surface of the earth. But below these are found masses of rock in which no trace of organic remains are found.—AGASSIZ *Structure of Animal Life*, lect. 4, p. 79. (S., 1883.)

194. ANTIQUITY OF MACHINES—*Bow-drill Used by Egyptians—Indians Obtain Fire by Same Means.*—The Dakotas used a drill-bow for the purpose of obtaining fire. This instrument is a small stiff bow, the string of which forms a loop round the upright stick, and thus, when the bow is moved backwards and forwards, gives it a rotatory movement. . . . The use of the bow-drill is very ancient. Ulysses used one to put out the eye of the unfortunate Cyclops. I myself, he says, twirled it round, while my companions pulled the "thong," and it requires no great stretch of the imagination to see the strap drill working until "the very roots of the eye hissed in the fire." The bow-drill was used still earlier by the Egyptians—even in the fourth dynasty.—AVEBURY *Prehistoric Times*, ch. 14, p. 500. (A., 1900.)

195. ANTIQUITY OF MAN—*Change in Estimate of—Archeology, Geology, and Culture Attest Remote Origin of the Human Race.*—It was until of late years commonly held among the educated classes that man's first appearance on earth might be treated on a historical basis as matter of record. It is true that the schemes drawn up by chronologists differed widely, as was naturally the case, considering the variety and inconsistency of their documentary data. On the whole, the scheme of Archbishop Usher, who computed that the earth and man were created in 4004 B. C., was the most popular. It is no longer neces-

sary, however, to discuss these chronologies. inasmuch as new evidence has so changed the aspect of the subject that the quasi-historical schemes of the last century would now hardly be maintained by any competent authority of any school. Geology, notwithstanding the imperfection of its results, has made it manifest that our earth must have been the seat of vegetable and animal life for an immense period of time; while the first appearance of man, tho comparatively recent, is positively so remote that an estimate between twenty and a hundred thousand years may fairly be taken as a minimum. This geological claim for a vast antiquity of the human race is supported by the similar claims of prehistoric archeology and the science of culture, the evidence of all three departments of inquiry being intimately connected and in perfect harmony.—Daniel Wilson *Anthropology*, ch. 5, p. 17. (Hum., 1885.)

196. ANTIQUITY OF POTTERY—*Homer's Mention*.—In the very earliest graves and camp-sites no fragments of pottery occur. If our first parents were makers thereof, we should know it, because this most brittle of human works is also among the most enduring. Fire-making devices were invented before pottery, because all of it was effected by means of fire, if we except sun-dried bricks and lamp-stoves. The bow and the arrow, the spear and the fish-hook, are older. They are found in older graves. Can it be that this art came in with the grinding of food? At any rate, it long antedated Homer, for the potter's wheel is mentioned by him (Il. xviii. 600). The simpler hand epoch antedates all books and writings, and there are many, many tribes of uncivilized peoples on the earth making beautiful ware who do not read at all. The lake-dwellers had pottery, and so had the mound-builders, and the people of very ancient Troy. In Peru beautiful specimens come from the oldest graves, and over the cañons of Colorado, and especially of its tributaries, hundreds of complete vessels, and millions of fragments, are scattered similar to that made near-by to-day.—Mason *Origins of Invention*, ch. 5, p. 154. (S., 1899.)

197. ANTIQUITY OF SEVEN-DAY WEEK—*Not Used by Greeks and Romans*.—Whichever of the three processes may have been used, the interesting point for us to know is that the division of time by periods of seven days is of the highest antiquity and due to the phases of the moon, but that it has not been in use among all nations, for the Greeks and Romans did not make use of it, the first having weeks of ten days (decades), and the second counting by kalends, ides, and nones. But it came into almost general use about the first century of our era.—Flammarion *Popular Astronomy*, bk. ii. ch. 2, p. 103. (A.)

198. ANTIQUITY OF SUN-WORSHIP—Every scholar knows, tho *littérateurs* and men of the world do not, that in the full vigor of the Greek religion the Sun and Moon, not a god and goddess thereof, were sacrificed to as deities—older deities than Zeus and his descendants, belonging to the earlier dynasty of the Titans (which was the mythical version of the fact that their worship was older)—and these deities had a distinct set of fables or legends connected with them.—Mill *Positive Philosophy of Auguste Comte*, p. 20. (H. H. & Co., 1887.)

199. ANTIQUITY OF THE ARCH—*Found in Tombs of Egypt—Neglect of, by Greeks—Skilful Use of, by Romans*.—In the tombs of ancient Egypt real arches are to be seen, constructed in mud-bricks, or later in stone, by architects who quite understood the principle. Yet tho the arch was known in what we call ancient times, it was not at once accepted by the world. It is remarkable that the Greek architects of the classic period never took to it. It was left to the Romans, who applied it with admirable skill, and from whose vaulted roofs, bridges, and domes those of the medieval and modern world are derived.—Tylor *Anthropology*, ch. 10, p. 235. (A., 1899.)

200. ANTIQUITY OF WEAVING—The textile art is older than the human species. For not only spiders and many caterpillars drew out extremely fine threads, but birds wove nests long before man's advent on earth. And, most significant of all, in tropical lands especially, trees and plants fabricated cloth, which men have worn from time immemorial, and on it they have also preserved their thoughts. There is no reason to doubt that the very first women were weavers of a crude kind, and that the textile art has been with us always in one form or another.—Mason *Origins of Invention*, ch. 7, p. 224. (S., 1899.)

201. ANTIQUITY, REMOTE, OF MOUND-BUILDERS—Where it [an ancient mound] is most distinct, it is from fifteen to twenty feet wide, by three or four in height. The area thus enclosed is about one hundred and forty acres, and the wall is two miles and a quarter in length. The stones themselves vary much in size, and Messrs. Squier and Davis suggest that the wall may originally have been about eight feet high, with an equal base. At present trees of the largest size are growing upon it. On a similar work known as "Fort Hill," Highland County, Ohio, Messrs. Squier and Davis found a splendid chestnut tree, which they suppose to be six hundred years old. "If," they say, "to this we add the probable period intervening from the time of the building of this work to its abandonment, and the subsequent period up to its invasion by the forest, we are led

irresistibly to the conclusion that it has an antiquity of at least one thousand years. But when we notice, all around us, the crumbling trunks of trees, half hidden in the accumulating soil, we are induced to fix on an antiquity still more remote."—AVEBURY *Prehistoric Times*, ch. 8, p. 244. (A., 1900.)

202. ANTITOXINS, THEORY OF—*Immunity of Patients after Recovery from Some Diseases—Bacteria Generate Their Own Destroyers.*—Whenever bacteria, introduced into the blood and tissues, fail to multiply or produce infection, this inability to perform their rôle is brought about by some property in the living and normal blood-serum which opposes their life and action. . . . Where the blood and tissues do not possess this power, the animal is susceptible. Now, as we have already seen from the experiments of Ogata, Kitasato, and others, the blood of an animal dead of anthrax is protective against anthrax, from which and the foregoing it appears that microbes produce by their growth in the tissues poisonous substances we term toxins, which have the power of producing in the blood and body cells substances inimical to themselves, named antitoxins, and so long as these latter substances remain in the tissues the body remains insusceptible to further attacks of the same disease.—NEWMAN *Bacteria*, ch. 7, p. 249. (G. P. P., 1899.)

203. ANTS, AMAZONS AMONG—*Preparation for Success in Warfare.*—This year I have constantly seen amazons from my ant-hill depart individually and go to a great distance (as far as fifty paces from their nests), marching by jerks. I have watched them inspecting four or five nests of the Fusca ants situated more than thirty paces distant, searching for their openings and examining their surroundings with care. These facts more and more convince me that each amazon studies on her own account the situation of the nests of the slaves in the neighborhood, and that that is what enables the army to direct itself with uniformity and to make a decision at any given moment.—FOREL *Les Fourmis de la Suisse*, p. 321. (Translated for *Scientific Side-Lights.)*

204. ANTS AS KEEPERS OF LIVE STOCK—*Property in Aphids.*—I have seen the ants of two neighboring nests in dispute over their plant-lice. If those from the one strayed into that of the other, these latter would rob them from the real owners, and often these in turn would rob the robbers. For ants are aware of the value of these tiny animals that seem to have been made for them. They form their wealth; an ant-hill is rich according to its number of plant-lice; they are their live stock, their cows and goats. We had never imagined that ants were a pastoral people.—HUBER *Recherches sur les Mœurs des Fourmis Indigènes*, p. 194. (Translated for *Scientific Side-Lights.)*

205. ANTS DOMESTICATE OTHER INSECTS—*Aphides "The Cows of the Ants."*—It has long been known that ants derive a very important part of their sustenance from the sweet juice excreted by aphides. These insects, in fact, as has been over and over again observed, are the cows of the ants; in the words of Linnæus, "Aphis formicarum vacca." A good account of the relations existing between ants and aphides was given more than a hundred years ago by the Abbé Boisier de Sauvages.—AVEBURY *Ants, Bees, and Wasps*, ch. 4, p. 67. (A., 1900.)

206. ANTS, MANIFESTATIONS OF FRIENDSHIP AMONG—When ants are friendly, they have a multitude of manifestations. Sometimes they conduct themselves as if not aware of each other's presence, only they show no fear, do not take flight; or rather they stop. Then again we see both of them patting their bodies with very lively concussion before and behind, or rapidly striking the forehead or any other part of the body and then separating. At other times only one of the two will perform this maneuver facing the other, which will feel about it for a time with her antennæ. On other occasions both remain motionless in body, only striking each other with their antennæ. This last act is a less sure sign of friendship, and we often witness it between ants in doubt whether they are dealing with an enemy or a friend. One almost never sees two friends menace one another by a jesting bite or curving their abdomens around at each other. Two particular manifestations are very characteristic between two friendly ants, disgorging, and carrying one another by mutual consent. If one of the two ants is hungry or thirsty, and especially if she perceives that the crop of the other is full, which she recognizes by feeling the abdomen with her antennæ, she asks for a drink. . . . The ant (granting the request) has the appearance of enjoying it and sometimes causes two or three drops to appear, one after the other. This act of disgorging plays a very important rôle in the economy of an ant-hill; it is a perfect sign that the two ants are friends.—FOREL *Les Fourmis de la Suisse*, p. 244. (Translated for *Scientific Side-Lights.)*

207. ANTS STORING GRAIN—*Solomon's Statement Verified—Objection Refuted by Fuller Knowledge.*—None of our northern ants store up grain, and hence there has been much discussion as to the well-known passage of Solomon. . . . It is, however, now a well-established fact that more than one species of southern ants do collect seeds of various kinds. The fact, of course, has long been known in those

regions. Indeed, the quantity of grain thus stored up is sometimes so considerable that in the "Mishna" rules are laid down with reference to it; and various commentators, including the celebrated Maimonides, have discussed at length the question whether such grain belonged to the owner of the land, or might be taken by gleaners—giving the latter the benefit of the doubt. They do not appear to have considered the rights of the ants.—AVEBURY *Ants, Bees, and Wasps*, ch. 3, p. 59. (A., 1900.)

208. ANTS, THE LEAF-CUTTING SPECIES OF—*Systematic Industry among—Insects Building Thatched Roofs of Cut Leaves.*—It is a most interesting sight to see the vast host of busy diminutive laborers [the Saüba ants] occupied on this work [of leaf-cutting]. Unfortunately they choose cultivated trees for their purpose. This ant is quite peculiar to tropical America, as is the entire genus to which it belongs; it sometimes despoils the young trees of species growing wild in its native forests, but seems to prefer, when within reach, plants imported from other countries, such as the coffee and orange trees. It has not hitherto been shown satisfactorily to what use it applies the leaves. I discovered this only after much time spent in investigation. The leaves are used to thatch the domes which cover the entrances to their subterranean dwellings, thereby protecting from the deluging rains the young broods in the nests beneath. The larger mounds, already described, are so extensive that few persons would attempt to remove them for the purpose of examining their interior; but smaller hillocks, covering other entrances to the same system of tunnels and chambers, may be found in sheltered places, and these are always thatched with leaves, mingled with granules of earth. The heavily laden workers, each carrying its segment of leaf vertically, the lower edge secured in its mandibles, troop up and cast their burdens on the hillock; another relay of laborers place the leaves in position, covering them with a layer of earthy granules, which are brought one by one from the soil beneath.—BATES *Naturalist on the River Amazon*, ch. 1, p. 627. (Hum., 1880.)

209. ANTS TRACKING ONE ANOTHER BY SCENT—*Huber's Experiment.*—That ants track one another by scent was long ago mentioned by Huber, and also that they depend on this sense for their power of finding supplies which have been previously found by other ants. Huber proved their power of tracking a path previously pursued by their friends, by drawing his finger across the trail, so obliterating the scent at that point, and observing that when the ants arrived at that point they became confused and ran about in various directions till they again came upon the trail on the other side of the interrupted space, when they proceeded on their way as before. The more numerous and systematic experiments of Sir John Lubbock have fully corroborated Huber's observations.—ROMANES *Animal Intelligence*, ch. 3, p. 33. (A., 1899.)

210. ANTS USELESS OR INJURIOUS TO FLOWERS—*Nature Shuts Them Off in Favor of Bees.*—If larger flowers were visited by ants, not only would they deprive the flowers of their honey without fulfilling any useful function in return, but they would probably prevent the really useful visits of bees. If you touch an ant with a needle or a bristle, she is almost sure to seize it in her jaws; and if bees, when visiting any particular plant, were liable to have the delicate tip of their proboscis seized on by the horny jaws of an ant, we may be sure that such a species of plant would soon cease to be visited. On the other hand, we know how fond ants are of honey, and how zealously and unremittingly they search for food. How is it then that they do not anticipate the bees, and secure the honey for themselves? This is guarded against in several ways [as by hairy or slippery surfaces, cups of water around the stem, etc.].—AVEBURY *Ants, Bees, and Wasps*, ch. 3, p. 51. (A., 1900.)

211. APES, ANTHROPOID, NOT FOUND IN AMERICA—*Spider-monkey the Limit of Development in the New World—Prehensile Tails Mark American Monkeys.*—The forest at Obydos seemed to abound in monkeys, for I rarely passed a day without seeing several. I noticed four species: the Coaitá *(Ateles paniscus)*, the *Chrysothrix sciureus*, the *Callithrix torquatus*, and our old Pará friend, *Midas ursulus*. The Coaitá is a large black monkey, covered with coarse hair, and having the prominent parts of the face of a tawny flesh-colored hue. It is the largest of the Amazonian monkeys in stature, but is excelled in bulk by the "Barrigudo" *(Lagothrix humboldtii)* of the Upper Amazons. It occurs throughout the lowlands of the Lower and Upper Amazons; but does not range to the south beyond the limits of the river plains. At that point an allied species, the white-whiskered Coaitá *(Ateles marginatus)*, takes its place. The Coaitás are called by zoologists spider-monkeys, on account of the length and slenderness of their body and limbs. In these apes the tail, as a prehensile organ, reaches its highest degree of perfection; and on this account it would, perhaps, be correct to consider the Coaitás as the extreme development of the American type of apes. As far as we know, from living and fossil species, the New World has progressed no farther than the Coaitá toward the production of a higher form of the Quadrumanous order. The tendency of nature here has been, to all appearance, simply to perfect those organs which adapt the species more and more

completely to a purely arboreal life; and no nearer approach has been made toward the more advanced forms of anthropoid apes, which are the products of the Old World solely.—BATES *Naturalist on the River Amazon*, ch. 6, p. 671. (Hum., 1880.)

212. APES, CIVILIZATION MEANS EXTINCTION OF — It is pretty certain, however, that were apes as like us mentally as they are bodily, that very similarity would result in a notable difference. Some men are radicals and some conservatives, but apes would give a solid vote for the most conservative ticket, since that progress and advance of civilization which pleases most of us means, ultimately, death to them.—MIVART *Types of Animal Life*, ch. 1, p. 2. (L. B. & Co., 1893.)

213. APPEAL FROM ILLUSIVE PRESENT TO CERTAINTIES OF THE PAST—*One Sense Called to Verify Another.*—It is plain that the illusoriness of a perception is in these cases determined in relation to the sense-impressions of other moments and situations, or to what are presumably better percepts than the present one. Sometimes this involves an appeal from one sense to another. Thus, there is the process of verification of sight by touch, for example, in the case of optical images, a mode of perception which . . . gives a more direct cognition of external quality. Conversely, there may occasionally be a reference from touch to sight, when it is a question of discriminating two points lying very close to one another. Finally, the same sense may correct itself, as when the illusion of the stereoscope is corrected by afterwards looking at the two separate pictures.—SULLY *Illusions*, ch. 3, p. 38. (A., 1897.)

214. APPEARANCE OF DESIGN ACKNOWLEDGED BY DARWIN—*The Testimony of Language—Contrivance and Purpose Recognized.*—It is curious to observe the language which this most advanced disciple of pure naturalism [Darwin] instinctively uses when he has to describe the complicated structure of this curious order of plants [the orchids]. "Caution in ascribing intentions to nature," does not seem to occur to him as possible. Intention is the one thing which he does see, and which, when he does not see, he seeks for diligently until he finds it. He exhausts every form of words and of illustration by which intention or mental purpose can be described. "Contrivance"—"curious contrivance"—"beautiful contrivance"—these are expressions which recur over and over again. Here is one sentence describing the parts of a particular species: "The Labellum is developed into a long nectary, in order to attract Lepidoptera, and we shall presently give reasons for suspecting that the nectar is purposely so lodged that it can be sucked only slowly, in order to give time for the curious chemical quality of the viscid matter setting hard and dry." ["Fertilization of Orchids," p. 29.] Nor are these words used in any sense different from that in which they are applicable to the works of man's contrivance—to the instruments we use or invent for carrying into effect our own preconceived designs. On the contrary, human instruments are often selected as the aptest illustrations, both of the object in view and of the means taken to effect it. Of one particular structure, Mr. Darwin says: "This contrivance of the guiding ridges may be compared to the little instrument sometimes used for guiding a thread into the eye of a needle." Again, referring to the precautions taken to compel the insects to come to the proper spot, in order to have the "pollinia" attached to their bodies, Mr. Darwin says: "Thus we have the rostellum partially closing the mouth of the nectary, like a trap placed in a run for game—and the trap so complex and perfect"! [ibid., p. 30].—ARGYLL *Reign of Law*, ch. 1, p. 23. (Burt.)

215. APPENDAGES, USELESS, VOLUNTARILY REMOVED—*Nature's Provision for Extended Life—Ants Winged for Mating in Distant Colonies.*—I noticed that the winged termites, or white ants, which came by hundreds to the lamps at night, when alighting on the table often jerked off their wings by a voluntary movement. On examination I found that the wings were not shed by the roots, for a small portion of the stumps remained attached to the thorax. The edge of the fracture was in all cases straight, not ruptured; there is, in fact, a natural seam crossing the member toward its root, and at this point the long wing naturally drops or is jerked off when the insect has no further use for it. The white ant is endowed with wings simply for the purpose of flying away from the colony peopled by its wingless companions, to pair with individuals of the same or other colonies, and thus propagate and disseminate its kind. The winged individuals are males and females, while the great bulk of their wingless fraternity are of no sex, but are of two castes, soldiers and workers, which are restricted to the functions of building the nests, nursing, and defending the young brood.—BATES *Naturalist on the River Amazon*, ch. 5, p. 664. (Hum., 1880.)

216. APPLIANCES, DEFECTIVE, MAY GIVE GREAT RESULTS—*Earnest Workers Win Astonishing Success.*—For a long time investigators were compelled to employ plates of tourmaline for this purpose [of studying polarized light], and the progress they made with so defective a means of inquiry is astonishing. But these men had their hearts in their work, and were on this account enabled to extract great results from small instrumental appliances. But for our present purpose we need far larger apparatus; and, happily, in these later times this need has been to a great

extent satisfied.—TYNDALL *Lectures on Light,* lect. 4, p. 124. (A., 1898.)

217. APPLICATION OF KNOWLEDGE FOLLOWS ACQUISITION—*Sense of Ignorance—Desire to Know.*—Without a sense of ignorance there could be no desire of knowledge, and without his desire of knowledge man would not be man. His whole place in nature depends upon it. His curiosity, and his wonder, and his admiration, and his awe—these are all but the adjuncts and subsidiary allies of that supreme affection which incites him to inquire and know. Nor is this desire capable of being resolved into his tendency to seek for an increased command over the comforts and conveniences of life. It is wholly independent of that kind of value which consists in the physical utility of things. The application of knowledge comes after the acquisition of it, and is not the only, or even the most powerful, inducement to its pursuit. The real incitement is an innate appetite of the mind—conscious in various degrees of the mystery, and of the beauty, and of the majesty of the system in which it lives and moves; conscious, too, that its own relations to that system are but dimly seen and very imperfectly understood.—ARGYLL *Unity of Nature,* ch. 9, p. 188. (Burt.)

218. APPROXIMATIONS, GRADUAL, TO SCIENTIFIC TRUTH—*Ancient Errors.*—The history of the contemplation of the universe, as I interpret its limits, designates not so much the frequently recurring oscillations between truth and error as the principal epochs of the gradual approximation to more accurate views regarding terrestrial forces and the planetary system. It shows us that the Pythagoreans . . . taught the progressive movement of the non-rotating earth, its revolution round the focus of the world (the central fire, *hestia*), while Plato and Aristotle imagined that the earth neither rotated nor advanced in space, but that, fixed to one central point, it merely oscillated from side to side. Aristarchus of Samos, and more particularly Seleucus of Babylon, who lived one hundred and fifty years after Alexander, first arrived at the knowledge that the earth not only rotated on its own axis, but also moved round the sun as the center of the whole planetary system. And if, in the dark period of the middle ages, Christian fanaticism, and the lingering influence of the Ptolemaic school, revived a belief in the immobility of the earth, . . . it must not be forgotten that a German cardinal, Nicholas de Cusa, was the first who had the courage and the independence of mind again to ascribe to our planet, almost a hundred years before Copernicus, both rotation on its axis and translation in space. After Copernicus, the doctrines of Tycho Brahe gave a retrograde movement to science, altho this was only of short duration; and when once a large mass of accurate observations had been collected, to which Tycho Brahe himself contributed largely, a correct view of the structure of the universe could not fail to be speedily established. A period of fluctuations between truth and error is especially one of presentiments and fanciful hypotheses regarding natural philosophy.—HUMBOLDT *Cosmos,* vol. ii, pt. ii, p. 109. (H., 1897.)

219. ARABS PRESERVED GREEK LEARNING—*Value of Their Translations.*—The repugnance entertained by all the adherents of Islamism toward anatomical investigations impeded their advance in zoology. They remained contented with that which they were able to appropriate to themselves from translations of the works of Aristotle and Galen. . . . The Arabs have served as a uniting link between ancient and modern science. If it had not been for them and their love of translation, a great portion of that which the Greeks had either formed themselves, or derived from other nations, would have been lost to succeeding ages.—HUMBOLDT *Cosmos,* vol. ii, pt. ii, p. 214, 216. (H., 1897.)

220. ARCHITECTS, MICROSCOPIC—*Chalk Cliffs Built by Minute Organisms.*—The great chalk cliffs that are found on the coasts of the English Channel are the work of a sea-animal microscopic in size. At one time it was a question among scientists how these chalk cliffs were formed, but when the microscope was invented this mystery, as well as many others, was solved. The chemical components of chalk are precisely the same as those of limestone. The microscope shows that chalk is almost wholly a product of very small organized shells. The animals who are the architects of the chalk cliffs are called "foraminifera"—bearing shells perforated with little holes. The chief difference between chalk and limestone seems to be in the size of the shells of which they are respectively made up and in the manner of the bonding of these shells together. The shells in a lump of chalk are held much more loosely than those in a lump of limestone. These intrepid workers are still actively changing the structure of the bottoms of seas and oceans, and forming new islands, which in turn become the substructure that supports new life, animal and vegetable. And when we consider the great part performed by these microscopic architects and builders it is not a misnomer to speak of the building of a world.—ELISHA GRAY *Nature's Miracles,* vol. i, ch. 2, p. 20. (F. H. & H., 1900.)

221. ARCHITECTURE AMONG INSECTS—*Ants Adapt Their Homes to Convenience and Comfort.*—The chief feature of ant architecture, in contradistinction to that of bees and wasps, is the irregularity, the want of uniformity, that is to say, its adaptability, or the capacity of making all

the surroundings and incidents subserve the purpose of attaining the greatest possible economy of space and time, and the most comfort. For instance, the same species will, in the Alps, live under stones that absorb the rays of the sun; in a forest it will live in warm, decayed trunks of trees; in a rich meadow it will live in high conical mounds of earth.—AUGUSTE FOREL *Fourmis de la Suisse*, p. 181. (Translated for *Scientific Side-Lights.)*

222. ARCHITECTURE, ANCIENT AND MODERN — *Sun-dried Bricks—Straw Mixed with Clay—Modern Adobe a Survival in Fact and Name from Ancient Egypt.*—Such hut-walls of clay or mud are very usual in dry climates, such as Egypt, where they are cheaper and better than timber. This being so, there is no difficulty in understanding how sun-dried bricks came into use, these being simply convenient blocks of the same mud or loam mixed with straw which was used to build the cottage walls. These sun-dried bricks were used in the East from high antiquity. Some of the Egyptian pyramids still standing are built of them, and the pictures show how the clay was tempered and the large bricks formed in wooden molds, much as in modern brick-fields. With these the architects of Nineveh built the palace walls ten or fifteen feet thick, which were paneled with the slabs of sculptured alabaster. For such sun-dried bricks, clay and water form a sufficient cement. Building with mud-bricks, which indeed suits the climate well, goes on in these countries as of old. They were used also in America, and to this day the traveler in such districts as Mexico will often find himself lodged in a house built of them. The sun-dried brick is there called *adobe*, a word which is actually their ancient Egyptian name *tob*, which when adopted into Arabic became with the article, *at-tob*, and thence was adopted into Spanish as *adobe*. Baked bricks seem to have been a later invention, easy enough to nations who baked earthen pots, but only wanted in more rainy climates. Thus the Romans, whom mere mud-bricks would not have suited, carried to great perfection the making of kiln-burnt bricks and tiles.—TYLOR *Anthropology*, ch. 10, p. 234. (A., 1899.)

223. ARCHITECTURE, DEVICES OF, ANTICIPATED—*Buttresses Built around Tropical Trees—Roots Spring Up to Sustain Massive Crown.*—A very remarkable feature in these trees is the growth of buttress-shaped projections around the lower part of their stems. The spaces between these buttresses, which are generally thin walls of wood, form spacious chambers, and may be compared to stalls in a stable; some of them are large enough to hold half a dozen persons. The purpose of these structures is as obvious, at the first glance, as that of the similar props of brickwork which support a high wall. They are not peculiar to one species, but are common to most of the larger forest-trees. Their nature and manner of growth are explained when a series of young trees of different ages is examined. It is then seen that they are the roots which have raised themselves ridge-like out of the earth; growing gradually upward as the increasing height of the tree required augmented support. Thus they are plainly intended to sustain the massive crown and trunk in these crowded forests, where lateral growth of the roots in the earth is rendered difficult by the multitude of competitors.—BATES *Naturalist on the Amazon*, ch. 2, p. 635. (Hum., 1880.)

224. ARCHITECTURE OF THE EARTH —*Basaltic Columns the Silent Memorials of Past Convulsions—Fingal's Cave—The Giant's Causeway.*—The remarkable grotto known as Fingal's Cave, in the Island of Staffa, has been formed in the midst of a lava-stream; the thick vertical columns, which rise from beneath the level of the sea, are divided by joints and have been broken away by the action of the sea; in this way a great cavern has been produced, the sides of which are formed by vertical columns, while the roof is made up of smaller and interlacing ones. The whole structure bears some resemblance to a Gothic cathedral; the sea finding access to its floor of broken columns, and permitting the entrance of a boat during fine weather. Similar, tho perhaps less striking, structures are found in many other parts of the globe wherever basaltic and other lava-streams exhibit the remarkable columnar structure as the result of their slow cooling. . . . This kind of structure is admirably displayed at the Giant's Causeway, County Antrim, in the north of Ireland.—JUDD *Volcanoes*, ch. 4, p. 107. (A., 1899.)

225. AREA, TRIFLING, OF CORAL ISLANDS—*Archipelago Less than a City.*—To show how small the total area of the annular reef and the land is in islands of this class [coral atolls], I may quote a remark from the voyage of Lutké, namely, that if the forty-three rings, or atolls, in the Caroline Archipelago were put one within another, and over a steeple in the center of St. Petersburg, the whole would not cover that city and its suburbs.—DARWIN *Coral Reefs*, ch. 1, p. 29. (A., 1900.)

226. ARGUMENT A PRIORI CANNOT DETERMINE FACT—*Popular Belief in Meteorites Scouted by Early Scientists.*—Among the many superstitions of the early world and credulous fancies of the middle ages was the belief that great stones sometimes fell down out of heaven onto the earth.

Pliny has a story of such a black stone, big enough to load a chariot; the Mussulman still adores one at Mecca; and a medieval emperor of Germany had a sword which was said to have been forged from

one of these bolts shot out of the blue. But with the revival of learning, people came to know better! That stones should fall down from the sky was clearly, they thought, an absurdity; indeed, according to the learned opinion of that time, one would hardly ask a better instance of the difference between the realities which science recognized and the absurdities which it condemned than the fancy that such a thing could be.—LANGLEY *New Astronomy*, ch. 6, p. 175. (H. M. & Co., 1896.)

227. ARGUMENT FROM DESIGN—*Plan Not Less Divine for Lapse of Time—Unity Perfect—Interpositions Not Needed.*—Accepting provisionally, then, the doctrine of evolution in this widest sense, as implying the common origin of the whole organized creation—past and present—from a single stock, we shall find that no further modification will be required in the form in which I have put the argument, from design, than such as gives it yet further range and greater comprehensiveness. For we must then regard our one ancestral germ-particle as endowed with a "potentiality" of progressive development that has been equal to the peopling of our globe with all that vast variety of living creatures, by some or other of which it has been inhabited through all save the remotest periods of its ever-changing history to the present time. That this progressive development has taken place according to an orderly succession, the study of which will ultimately enable us to frame "laws" that shall express the conditions of the "perturbations" as well as of the "uniformities" of genetic descent, is the belief of every philosophic biologist. But when biological science shall have reached this elevated point, it will have revealed to us only the order of the evolutionary process, leaving us still to seek for its cause. But how much grander a conception of that order do we obtain when we are thus led to regard it as embodied in one original design continuously working itself out through the ages, in constant harmony with the changes contemporaneously taking place in the condition of the terrestrial surface, than when we suppose it to have needed successive interpositions for readaptation to those changes as they successively occurred!—CARPENTER *Nature and Man*, lect. 15, p. 434. (A., 1889.)

228. ARITHMETIC OF PRIMITIVE MAN—*Standards of Computation Limited.*—The standards of compound arithmetic were very low among the Andamanese. About forty pounds was a man's load, and anything above that would simply be more than a man's load. Size was rated by well-known natural objects, seeds, fruits, nuts, etc. Capacity was counted by handfuls, basketfuls, bucketfuls, canoefuls. There is no prescribed form or dimensions for any object. No tallies were kept nor counters, and this is very low down, because all American tribes knew the use of tallies. Distance was spoken of as a bowshot, or as from there to there, indicating the limits Fifteen miles, about, was a day's journey, and over that was said to "exceed a day's journey."—MASON *Origins of Invention*, ch. 2, p. 69. (S., 1899.)

229. ARMOR DERIVED FROM ANIMALS—*The Cuirass Originally of Leather—Later Imitation of the Scales of Fish or Reptile.*—How the warrior's armor comes from the natural armor of animals is plainly to be seen. The beast's own hide may be used, as where one sees in museums the armor of bearskins from Borneo, or breastplates of crocodile's skin from Egypt. The name of the cuirass shows that it was at first of leather, like the buff jerkin. The Bugis of Sumatra would make a breastplate by sewing upon bark the cast-off scales of the ant-eater, overlapping as the animal wore them; and so the natural armor of animals was imitated by the Sarmatians, with their slices of horses' hoofs sewed together in overlapping scales like a fir-cone. Such devices, when metal came in, would lead to the scale armor of the Greeks, imitated from fish-scales and serpent-scales, while their chain-mail is a sort of netted garment made in metal. The armor of the middle ages continued the ancient kinds, now protecting the whole body with a suit from head to foot (cap-à-pie) of iron scales, or mail (that is, meshes), or of jointed plates of iron copied from the crab and lobster, such as the later suits of armor which decorate our manorial halls.—TYLOR *Anthropology*, ch. 9, p. 222. (A., 1899.)

230. ARREST OF THE BODY—*Man Walking Erect and Making Tools Thenceforth Developed Mind.*—From the time when the ancestral man first walked erect, with hands freed from any active part in locomotion, and when his brain-power became sufficient to cause him to use his hands in making weapons and tools, houses and clothing, to use fire for cooking, and to plant seeds or roots to supply himself with stores of food, the power of natural selection would cease to act in producing modifications of his body, but would continuously advance his mind through the development of its organ, the brain. Hence man may have become truly man—the species, *Homo sapiens*—even in the Miocene period; and while all other mammals were becoming modified from age to age under the influence of ever-changing physical, and biological conditions, he would be advancing mainly in intelligence, but perhaps also in stature, and by that advance alone would be able to maintain himself as the master of all other animals and as the most wide-spread occupier of the earth.—WALLACE *Darwinism*, ch. 15, p. 308. (Hum.)

231. ——— ——— *Man Will Develop No Further as an Animal.*—"On the earth there will never be a higher creature than man" (Fiske, "Destiny of Man," p. 26). It is a daring prophecy, but every probability of science attests the likelihood of its fulfilment.

This is not a conceit of science, nor a reminiscence of the pre-Copernican idea that the center of the universe is the world, and the center of the world man. It is the sober scientific probability that with the body of man the final fruit of the tree of organic evolution has appeared; that the highest possibilities open to flesh and bone and nerve and muscle have now been realized; that in whatever direction, and with whatever materials, evolution still may work, it will never produce any material thing more perfect in design or workmanship; that in man, in short, about this time in history, we are confronted with a stupendous crisis in Nature—the arrest of the animal.—DRUMMOND *Ascent of Man,* ch. 3, p. 99. (J. P., 1900.)

232. ARREST OF THE HAND—*Tools Are External Hands.*—As the hand was given more and more to do, it became more and more adapted to its work. Up to a point, it responded directly to each new duty that was laid upon it; but only up to a point. There came a time when the necessities became too numerous and too varied for adaptation to keep pace with them. And the fatal day came, the fatal day for the hand, when he who bore it made a new discovery. It was the discovery of tools. Henceforth what the hand used to do, and was slowly becoming adapted to do better, was to be done by external appliances; so that if anything new arose to be done, or to be better done, it was not a better hand that was now made, but a better tool. Tools are external hands. Levers are the extensions of the bones of the arm. Hammers are callous substitutes for the fist. Knives do the work of nails. The vise and the pincers replace the fingers. The day that caveman first split the marrow-bone of a bear by thrusting a stick into it, and striking it home with a stone—that day the doom of the hand was sealed.—DRUMMOND *Ascent of Man,* ch. 3, p. 102. (J. P., 1900.)

233. ART AMONG ANCIENT CAVE-MEN—*Forgeries Detected by Lack of Antique Skill—Pictures Made by Australian and South African Savages.*—The sketches and carvings of animals done by the old cave-men of Europe have so artistic a touch that some have supposed them modern forgeries. But they are admitted to be genuine and found over a wide district, while forgeries which have been really done to palm off on collectors are just wanting in the peculiar skill with which the savages who lived among the reindeer and mammoths knew how to catch their forms and attitudes. . . . The art of coloring would naturally arise, for savages who paint their own bodies with charcoal, pipe-clay, and red and yellow ocher, would daub their carved figures and fill in their outline drawings with the same colors. Travelers in Australia, sheltering from the storm in caves, wonder at the cleverness of the rude frescos on the cavern-walls of kangaroos and emus and natives dancing, while in South Africa the bushmen's caves show paintings of themselves with bows and arrows, and the bullock-wagons of the white men, and the dreaded figure of the Dutch Boer with his broad-brimmed hat and pipe.—TYLOR *Anthropology,* ch. 12, p. 301. (A., 1899.)

234. ARTIFICIALITY DESTROYS MENTAL FREEDOM—*True Love of Nature Wanting in Persian Poetry.*—Both Iran and Turan are wanting in woodland scenery, and also, therefore, in the hermit life of the forest, which exercised so powerful an influence on the imagination of the Indian poets. Gardens refreshed by cool springs, and filled with roses and fruit-trees, can form no substitute for the wild and grand natural scenery of Hindustan. It is no wonder, then, that the descriptive poetry of Persia was less fresh and animated, and that it was often heavy and overcharged with artificial adornment. . . . Sadi, in his *Bostan and Gulistan* (Fruit and Rose Gardens), may be regarded as indicating an age of ethical teaching, while Hafiz, whose joyous views of life have caused him to be compared to Horace, may be considered by his love-songs as the type of a high development of lyrical art; but in both bombastic affectation too frequently mars the descriptions of nature. The darling subject of Persian poetry, the "loves of the nightingale and the rose," recurs with wearying frequency, and a genuine love of nature is lost in the East amid the artificial conventionalities of the language of flowers.—HUMBOLDT *Cosmos,* vol. ii. pt. i. p. 54. (H., 1897.)

235. ARTISAN MAY BECOME A SCHOLAR—*Opportunities of Stone-mason in Geology.*—I advise the stone-mason, for instance, to acquaint himself with geology. Much of his time must be spent amid the rocks and quarries of widely separated localities. . . . In some respects his advantages are superior to those of the amateur himself. The latter must often pronounce a formation unfossiliferous when, after the examination of at most a few days, he discovers in it nothing organic; and it will be found that half the mistakes of geologists have arisen from conclusions thus hastily formed. But the working man, whose employments have to be carried on in the same formation for months, perhaps years, together, enjoys better opportunities for arriving at just decisions. There are, besides, a thousand varieties of accident which lead to discovery—floods, storms, landslips, tides of unusual height, ebbs of

extraordinary fall: and the man who plies his labor at all seasons in the open air has by much the best chance of profiting by these. There are formations which yield their organisms slowly to the discoverer, and the proofs which establish their place in the geological scale more tardily still. I was acquainted with the old red sandstone of Ross and Cromarty for nearly ten years ere I had ascertained that it is richly fossiliferous—a discovery which, in exploring this formation in those localities, some of our first geologists had failed to anticipate. I was acquainted with it for nearly ten years more ere I could assign to its fossils their exact place in the scale.—MILLER *The Old Red Sandstone*, ch. 1, p. 13. (G. & L., 1851.)

236. ARTIST FEARING BLINDNESS—*Scientist Explains Difficulty—Prediction of Recovery Fulfilled.*—One of the most interesting cases of diffraction by small particles that ever came before me was that of an artist whose vision was disturbed by vividly colored circles. He was in great dread of losing his sight; assigning as a cause of his increased fear that the circles were becoming larger and the colors more vivid. I ascribed the colors to minute particles in the humors of the eye, and ventured to encourage him by the assurance that the increase of size and vividness on the part of the circles indicated that the diffracting particles were becoming smaller, and that they might finally be altogether absorbed. The prediction was verified.—TYNDALL *Lectures on Light*, lect. 2, p. 92. (A., 1898.)

237. ARTIST, SCIENTIFIC BLUNDER OF—*Asiatic Monkey Given Prehensile Tail.*—An amusing illustration of the wide-spread ignorance which exists as to such matters, and also of the use of the imagination in a way not strictly scientific, occurred with reference to the Prince of Wales's visit to India some years ago. Among other places of interest the Prince visited was the Temple of Monkeys at Benares. His visit was duly depicted in one of the illustrated journals, and no doubt with scrupulous fidelity in all these points to which the artist directed his attention. Nevertheless these monkeys are represented as having prehensile tails; which is about as accurate as would be a picture of a fox-hunt by a supposed eye-witness wherein the hounds should be represented each with a fox's brush for tail [none but American monkeys having prehensile tails].—MIVART *Types of Animal Life*, ch. 1, p. 5. (L. B. & Co., 1893.)

238. ARTIST, SELECTION THE SECRET OF HIS POWER—*Beauty of Works of Art Due to Elimination.*—The artist selects his items, rejecting all tones, colors, shapes, which do not harmonize with each other and with the main purpose of his work. That unity, harmony, "convergence of characters," as M. Taine calls it, which gives to works of art their superiority over works of nature, is wholly due to elimination. Any natural subject will do, if the artist has wit enough to pounce upon some one feature of it as characteristic, and suppress all merely accidental items which do not harmonize with this.—JAMES *Psychology*, vol. i, ch. 9, p. 287. (H. H. & Co., 1899.)

239. ARTS AND SCIENCES, GROWTH OF—*From Bow through Crossbow to Musket.*—Arts and sciences never spring forth perfect, like Athene out of the split head of Zeus. They come on by successive steps, and where other information fails the observer may often trust himself to judge from the mere look of an invention how it probably arose. Thus no one can look at a crossbow and a common longbow without being convinced that the longbow was the earlier, and that the crossbow was made afterwards by fitting a common bow on a stock, and arranging a trigger to let go the string after taking aim. Tho history fails to tell us who did this and when, we feel almost as sure of it as of the known historical facts that the crossbow led up to the matchlock, and that again to the flint-lock musket, and that again to the percussion musket, and that again to the breech-loading rifle.—TYLOR *Anthropology*, ch. 1, p. 18. (A., 1899.)

240. ASCENT FROM BRUTE TO MAN—*Alpine Heights of Intellect—Marvelous Endowment of Speech—Spiritual Exaltation.*—Nay, more; thoughtful men, once escaped from the blinding influences of traditional prejudice, will find in the lowly stock whence man has sprung the best evidence of the splendor of his capacities, and will discern in his long progress through the past a reasonable ground of faith in his attainment of a nobler future.

They will remember that in comparing civilized man with the animal world one is as the Alpine traveler, who sees the mountains soaring into the sky, and can hardly discern where the deep-shadowed crags and roseate peaks end and where the clouds of heaven begin. Surely the awe-struck voyager may be excused if at first he refuses to believe the geologist, who tells him that these glorious masses are, after all, the hardened mud of primeval seas, or the cooled slag of subterranean furnaces—of one substance with the dullest clay, but raised by inward forces to that place of proud and seemingly inaccessible glory.

But the geologist is right: and due reflection on his teachings, instead of diminishing our reverence and our wonder, adds all the force of intellectual sublimity to the more esthetic intuition of the uninstructed beholder.

And after passion and prejudice have died away the same result will attend the teachings of the naturalist respecting that great Alps and Andes of the living world—

man. Our reverence for the nobility of manhood will not be lessened by the knowledge that man is, in substance and in structure, one with the brutes: for he alone possesses the marvelous endowment of intelligible and rational speech whereby, in the secular period of his existence, he has slowly accumulated and organized the experience which is almost wholly lost with the cessation of every individual life in other animals; so that now he stands raised upon it as on a mountain-top, far above the level of his humble fellows, and transfigured from his grosser nature by reflecting, here and there, a ray from the infinite source of truth.—HUXLEY *Man's Place in Nature*, p. 234. (Hum.)

241. ASPIRATION OF SCIENCE LIMITLESS — The idea of limitation to thought or achievement no longer enters the imagination. The depth of the sea, the distances of the stars, the concealment of the earth's treasures, the minuteness of the springs of life and sense, the multiplicity and complicity of phenomena are only so many incitements to greater achievements. The daring souls of this decade are determined at any risk to answer the inquiry of Pontius Pilate, What is truth? With sympathetic enthusiasm we wave them on, bidding them Godspeed.—MASON *The Birth of Invention.* An Address. [Washington, D. C., 1891.]

242. ASSIMILATION OF COLOR TO ENVIRONMENT—*Transparency of Pelagic Animals.*—An . . . illustration of general assimilation of color to the surroundings of animals is furnished by the inhabitants of the deep oceans. Professor Moseley, of the Challenger Expedition, in his British Association lecture on this subject, says: "Most characteristic of pelagic animals is the almost crystalline transparency of their bodies. So perfect is this transparency that very many of them are rendered almost entirely invisible when floating in the water, while some, even when caught and held up in a glass globe, are hardly to be seen. The skin, nerves, muscles, and other organs are absolutely hyaline and transparent, but the liver and digestive tract often remain opaque and of a yellow or brown color, and exactly resemble when seen in the water small pieces of floating seaweed." Such marine organisms, however, as are of larger size, and either occasionally or habitually float on the surface, are beautifully tinged with blue above, thus harmonizing with the color of the sea as seen by hovering birds; while they are white below, and are thus invisible against the wave-foam and clouds as seen by enemies beneath the surface. Such are the tints of the beautiful nudibranchiate mollusk, *Glaucus atlanticus*, and many others.—WALLACE *Darwinism*, ch. 5, p. 132. (Hum., 1889.)

243. ASSOCIATION A SOURCE OF POWER—*Gregarious Animals, However Defenseless, Survive—Each Has the Foresight and Perception of the Herd.*—One of these advantages [of gregariousness], obviously, is the mere physical strength of numbers. But there is another and a much more important one—the mental strength of a combination. Here is a herd of deer, scattered, as they love to be, in a string, a quarter of a mile long. Every animal in the herd not only shares the physical strength of all the rest, but their powers of observation. Its foresight in presence of possible danger is the foresight of the herd. It has as many eyes as the herd, as many ears, as many organs of smell; its nervous system extends throughout the whole space covered by the line; its environment, in short, is not only what it hears, sees, smells, touches, tastes, but what every single member hears, sees, smells, touches, tastes. This means an enormous advantage in the struggle for life. What deer have to arm themselves most against is surprise. When it comes to an actual fight, comrades are of little use. At that crisis the others run away and leave the victims to their fate. But in helping one another to avert that crisis, the value of this mutual aid is so great that gregarious animals, for the most part timid and defenseless as individuals, have survived to occupy in untold multitudes the highest places in nature.—DRUMMOND *Ascent of Man*, p. 155. (J. P., 1900.)

244. ASSOCIATION IN THOUGHT—*Interdependence of the Various Parts of the Brain.*—Every namable thing, act, or relation has numerous properties, qualities, or aspects. In our minds the properties of each thing, together with its name, form an associated group. If different parts of the brain are severally concerned with the several properties, and a farther part with the hearing, and still another with the uttering, of the name, there must inevitably be brought about (through the law of association) such a dynamic connection amongst all these brain-parts that the activity of any one of them will be likely to awaken the activity of all the rest. When we are talking as we think, the ultimate process is that of utterance. If the brain-part for that be injured, speech is impossible or disorderly, even tho all the other brain-parts be intact.—JAMES *Psychology*, vol. i, ch. 2, p. 57. (H. H. & Co., 1899.)

245. ASSOCIATION OF THE IMPRESSIONS OF DIFFERENT SENSES—*Touch Awakens Memories of Sight and Sound.*—Association occurs as amply between impressions of different senses as between homogeneous sensations. Seen things and heard things cohere with each other, and with odors and tastes, in representation, in the same order in which they cohered as impressions of the outer world. Feelings of contact reproduce similarly the sights,

sounds, and tastes with which experience has associated them. In fact, the "objects" of our perception, as trees, men, houses, microscopes, of which the real world seems composed, are nothing but clusters of qualities which through simultaneous stimulation have so coalesced that the moment one is excited actually it serves as a sign or cue for the idea of the others to rise. Let a person enter his room in the dark and grope among the objects there. The touch of the matches will instantaneously recall their appearance. If his hand comes in contact with an orange on the table, the golden yellow of the fruit, its savor and perfume will forthwith shoot through his mind. In passing the hand over the sideboard or in jogging the coal-scuttle with the foot, the large, glossy, dark shape of the one and the irregular blackness of the other awaken like a flash and constitute what we call the recognition of the objects. The voice of the violin faintly echoes through the mind as the hand is laid upon it in the dark, and the feeling of the garments or draperies which may hang about the room is not understood till the look correlative to the feeling has in each case been resuscitated. . . . We cannot hear the din of a railroad train or the yell of its whistle without thinking of its long, jointed appearance and its headlong speed, nor catch a familiar voice in a crowd without recalling, with the name of the speaker, also his face.—JAMES *Psychology*, vol. i, ch. 14, p. 555. (H. H. & Co., 1899.)

246. ASSOCIATION, THE SPIRIT OF —*Power of Voluntary Societies—Church—Country.*—New motives can be evoked and put in action by the adopting of appropriate means. The mere founding, for example, of a voluntary society for any given purpose evolves out of the primary elements of human character a latent force of the most powerful kind, namely, the motive—the sentiment—the feeling—the passion, as it often is, of the spirit of association. This is a passion which defies analysis. The cynic may reduce it to a form of selfishness—and undoubtedly the identification of the interests, and the desires of self with the society for which this passion is conceived, lies at its very root and is of its very essence. It is true, also, that it is a passion so powerful as to need strong control—without which control it generates some of the very meanest emotions of the heart. Out of it there has come, and there comes again and again from age to age, a spirit of hatred even against good itself, when that good is the work of any one who "followeth not us." It is a force, nevertheless, rooted in the nature of man, implanted there as part of its constitution, and, like all others of this character, given him for a purpose, and having its own legitimate field of operation. Nor is that field a narrow one. The spirit of association is the fountain of much that is noblest in human character, and of much that is most heroic in human conduct. For all the desires and aspirations of self are not selfish. The interests of self, justly appreciated and rightly understood, may be, nay indeed must be, the interests also of other men—of society —of country—of the church, and of the world.—ARGYLL *Reign of Law*, ch. 7, p. 219. (Burt.)

247. ASSUMPTION NECESSARY TO MAINTAIN A THEORY—*Spontaneous Generation Never Known—Assumed in Order to Dispense with a Creator.*—The origin of the first Monera by spontaneous generation appears to us as a simple and necessary event in the process of the development of the earth. We admit that this process, as long as it is not directly observed or repeated by experiment, remains a pure hypothesis. But I must again say that this hypothesis is indispensable for the consistent completion of the non-miraculous history of creation, that it has absolutely nothing forced or miraculous about it, and that certainly it can never be positively refuted. It must also be taken into consideration that the process of spontaneous generation, even if it still took place daily and hourly, would in any case be exceedingly difficult to observe and establish with absolute certainty as such. This is also the opinion of Naegeli, the ingenious investigator, and he, in his admirable chapter on spontaneous generation, maintains that "to deny spontaneous generation is to proclaim miracles."—HAECKEL *History of Creation*, vol. i, ch. 15, p. 422. (K. P. & Co., 1899.)

248. ASSUMPTIONS OF MONISM—*Spontaneous Generation Never Proved—Mind to Be Evolved from Fire-mist—Faith Demanded in Philosophic Creed.*—It is plain that we might here enter our dissent from Haeckel's method, for he requires us, before we can proceed a single step in the evolution of man, to assume many things which he cannot prove. What evidence is there, for example, of the possibility of the development of the rational and moral nature of man from the intelligence and the instinct of the lower animals, or of the necessary dependence of the phenomena of mind on the structure of brain-cells? The evidence, so far as it goes, seems to tend the other way. What proof is there of the spontaneous evolution of living forms from inorganic matter? Experiment so far negatives the possibility of this. Even if we give Haeckel, to begin with, a single living cell or granule of protoplasm, we know that this protoplasm must have been produced by the agency of a living vegetable cell previously existing: and we have no proof that it can be produced in any other way. Again, what particle of evidence have we that the atoms or the energy of an incandescent fire-mist have in them anything of

the power or potency of life? We must grant the monist all these postulates as pure matters of faith before he can begin his demonstration; and, as none of them are axiomatic truths, it is evident that so far he is simply a believer in the dogmas of a philosophic creed, and in this respect weak as other men whom he affects to despise.—DAWSON *Facts and Fancies in Modern Science*, lect. 1, p. 58. (A. B. P. S.)

249. ASSURANCE OF OUR OWN REALITY — We reach thus the important conclusion that our own reality, that sense of our own life which we at every moment possess, is the ultimate of ultimates for our belief. "As sure as I exist!"—this is our uttermost warrant for the being of all other things.—JAMES *Psychology*, vol. ii, ch. 21, p. 297. (H. H. & Co., 1899.)

250. ASTEROIDS, COUNTLESS HOST OF—*Photography Surpasses the Human Eye in Observing—Study of This Band a Special Department of Science.*—The detection of new members of the solar system has come to be one of the most ordinary of astronomical events. Since 1846 no single year has passed without bringing its tribute of asteroidal discovery. . . . Both [time and diligence] are vastly economized by the photographic method. Tedious comparisons of the sky with charts are no longer needed for the identification of unrecorded, because simulated, stars. Planetary bodies declare themselves by appearing upon properly exposed sensitive plates, not in circular, but in linear form. Their motion converts their images into trails, long or short according to the time of exposure. . . . Far more onerous than the task of their discovery is that of keeping them in view once discovered—of tracking out their paths, fixing their places, and calculating the disturbing effects upon them of the mighty Jovian mass. These complex operations have come to be centralized at Berlin under the superintendence of Professor Tietjen, and their results are given to the public through the medium of the *Berliner Astronomisches Jahrbuch.*—CLERKE *History of Astronomy*, pt. ii, ch. 8, p. 346. (Bl., 1893.)

251. ASTRONOMY A CONTINUOUS SCIENCE—*Each Discoverer Builds on Previous Discoveries.*—The theory of universal gravitation was founded by Newton upon the laws of Kepler, the observations and measurements of his French contemporaries, and the geometry of Apollonius. Kepler used as his material the observations of Tycho Brahe, and built upon the theory of Copernicus. When we seek the origin of the instruments used by Tycho, we soon find ourselves among the medieval Arabs. The discovery of the true system of the world by Copernicus was only possible by a careful study of the laws of apparent motion of the planets as expressed in the epicycles of Ptolemy and Hipparchus. Indeed, the more carefully one studies the great work of Copernicus, the more surprised he will be to find how completely Ptolemy furnished him both ideas and material. If we seek the teachers and predecessors of Hipparchus, we find only the shadowy forms of Egyptian and Babylonian priests, whose names and writings are all entirely lost. In the earliest historic ages, men knew that the earth was round; that the sun appeared to make an annual revolution among the stars; and that eclipses were caused by the moon entering the shadow of the earth, or the earth that of the moon.—NEWCOMB *Popular Astronomy*, pt. i, int., p. 1. (H., 1899.)

252. ASTRONOMY, FASCINATION OF—*Compared with Novel-reading—Astronomy Instructs—The Novel Gives No Advance in Knowledge.*—Such a book [a popular treatise on astronomy], altho of more real interest and more attractive than a novel, should be read with attention, and only on this condition can the ideas it contains impart lasting scientific instruction. But whereas when we reach the last page of a novel we know just as much as when we began the first, we must be either blind or oblivious to all intellectual apprehension if the reading of a scientific work does not greatly extend the sphere of our knowledge, and does not more and more elevate the level of our judgment. We might even say that in our age it should be impossible for any one's mind to be so little cultivated as to remain in ignorance of the absolute truths revealed by the grand conquests of modern astronomy.—FLAMMARION *Popular Astronomy*, p. 2. (A.)

253. ASTRONOMY, GENERALIZATIONS OF—*The Indefinitely Great and the Indefinitely Little Alike Her Province.*—Astronomy generalizes the results of other sciences. She exhibits the laws of Nature working over a wider area, and under more varied conditions, than ordinary experience presents. Ordinary experience, on the other hand, has become indispensable to her progress. She takes in at one view the indefinitely great and the indefinitely little. The mutual revolutions of the stellar multitude during tracts of time which seem to lengthen out to eternity as the mind attempts to traverse them, she does not admit to be beyond her ken; nor is she indifferent to the constitution of the minutest atom of matter that thrills the ether into light.—CLERKE *History of Astronomy*, int., p. 9. (Bl., 1893.)

254. ASTRONOMY IN ANCIENT EGYPT—*Discoveries Recorded in Structure of the Pyramids.*—The Egyptians, who built the great pyramids more than forty centuries ago, constructed the passages which permit us to penetrate into the interior exactly in the direction of the north, and at an inclination of 27 degrees, which is precisely

the altitude which the pole star of that day, α Draconis, attained at its lower transit across the meridian.—FLAMMARION *Popular Astronomy*, p. 39. (A.)

255. ASTRONOMY IN CHINA—*More Fitly Termed Astrology—Calculations Grossly Erroneous.*—Arguments in support of the presumed knowledge of the Chinese regarding navigation are often based on their alleged attainments in astronomy; for they have undoubtedly studied the phenomena dealt with by that science since time immemorial. But their calculations of eclipses have been found erroneous; and the astronomer Cassini, in examining an observation of one winter solstice very celebrated in their annals, discovered therein an error of no less than 487 years. They are rather astrologers than astronomers, and their tribunal of mathematics, existing, as it has, for centuries, has found its chief occupation in indicating to the government fortunate days for national enterprises or ceremonials rather than in gathering the results of observation. In brief, their system of astronomy is rigidity itself, and if its predictions fail they argue that the fault is not in themselves, but in their stars, and settle the matter by deferring further prophecy until after the event.—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 3, p. 79. (J. W., 1898.)

256. ASTRONOMY MADE POSSIBLE BY MATHEMATICS—*Ancient Thinkers Prepared the Way for Modern Discoverers—Reason Directs the Telescope.*—The age of the Ptolemies was a most brilliant epoch in the prosecution of mathematical investigations. In the same century there appeared Euclid, the creator of mathematics as a science; Apollonius of Perga, and Archimedes, who visited Egypt, and was connected through Conon with the school of Alexandria. The long period of time which leads from the so-called geometrical analysis of Plato . . . to the age of Kepler and Tycho Brahe, Euler and Clairaut, D'Alembert and Laplace, is marked by a series of mathematical discoveries without which the laws of the motion of the heavenly bodies and their mutual relations in the regions of space would not have been revealed to mankind. While the telescope serves as a means of penetrating space, and of bringing its remotest regions nearer to us, mathematics, by inductive reasoning, have led us onward to the remotest regions of heaven, and brought a portion of them within the range of our possession; nay, in our own times—so propitious to extension of knowledge—the application of all the elements yielded by the present condition of astronomy has even revealed to the intellectual eye a heavenly body, and assigned to it its place, orbit, and mass, before a single telescope had been directed toward it. —HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 179. (H., 1897.)

257. ASTRONOMY OF ANTIQUITY—*Substitute for the Telescope—Lensless Tubes Excluded Diffused Light.*—We find, without including the epoch of the Chaldeans, Egyptians, and Chinese, that more than nineteen centuries intervened between the age of Timochares and Aristillus and the discoveries of Galileo, during which period the position and course of the stars were observed by the eye alone, unaided by instruments. . . . We are astonished that Hipparchus and Ptolemy should have been so well acquainted with the precession of the equinoxes, the complicated movements of the planets, the two principal inequalities of the moon, and the position of the stars; that Copernicus should have had so great a knowledge of the true system of the universe; and that Tycho Brahe should have been so familiar with the methods of practical astronomy before the discovery of the telescope. Long tubes, which were certainly employed by Arabian astronomers, and very probably also by the Greeks and Romans, may indeed, in some degree, have increased the exactness of the observations by causing the object to be seen through diopters or slits. Abul-Hassan speaks very distinctly of tubes, to the extremities of which ocular and object diopters were attached; and instruments so constructed were used in the observatory founded by Hulagu at Meragha. If stars be more easily discovered during twilight by means of tubes, and if a star be sooner revealed to the naked eye through a tube than without it, the reason lies, as Arago has already observed, in the circumstance that the tube conceals a great portion of the disturbing light diffused in the atmospheric strata between the star and the eye applied to the tube. In like manner, the tube prevents the lateral impression of the faint light which the particles of air receive at night from all the other stars in the firmament. The intensity of the image and the size of the star are apparently augmented. In a frequently emendated and much contested passage of Strabo, in which mention is made of looking through tubes, this "enlarged form of the stars" is expressly mentioned, and is erroneously ascribed to refraction.—HUMBOLDT *Cosmos*, vol. iii, p. 42. (H., 1897.)

258. ASTRONOMY OF THE EARLY WORLD—*A Slow Growth through Protracted Observation.*—Wherever steppes, grassy plains, or sandy wastes present a far-extended horizon, those constellations whose rising or setting corresponds with the busy seasons and requirements of pastoral and agricultural life have become the subject of attentive consideration, and have gradually led to a symbolizing connection of ideas. Men thus became familiarized with the aspect of the heavens before the development of measuring astronomy. They soon perceived that besides the daily movement from east to west, which is common

to all celestial bodies, the sun has a far slower proper motion in an opposite direction. The stars which shine in the evening sky sink lower every day, until at length they are wholly lost amid the rays of the setting sun; while, on the other hand, those stars which were shining in the morning sky, before the rising of the sun, recede further and further from it. In the ever-changing aspect of the starry heavens successive constellations are always coming to view. A slight degree of attention suffices to show that these are the same which had before vanished in the west, and that the stars which are opposite to the sun, setting at its rise and rising at its setting, had about half a year earlier been seen in its vicinity. From the time of Hesiod to Eudoxus, and from the latter to Aratus and Hipparchus, Hellenic literature abounds in metaphoric allusions to the disappearance of the stars amid the sun's rays, and their appearance in the morning twilight—their heliacal setting and rising. An attentive observation of these phenomena yielded the earliest elements of chronology, which were simply expressed in numbers, while mythology, in accordance with the more cheerful or gloomy tone of national character, continued simultaneously to rule the heavens with arbitrary despotism.—HUMBOLDT *Cosmos*, vol. iii, p. 118. (H., 1897.)

259. ASTRONOMY ORIGINATED WITH THE MOON—The light of the moon was the first astronomical illumination. Science commenced with this dawn, and age by age it has conquered the stars and the immense universe. This sweet and calm light releases our thoughts from terrestrial bonds and compels us to think of the sky; then the study of other worlds develops, observations increase, and astronomy is founded. It is not yet the heavens, and it is already more than the earth. The silent star of night is the first halting-place on a voyage towards the infinite.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 1, p. 81. (A.)

260. ASTRONOMY, PRECISION OF—*Eclipses Predicted Centuries in Advance—Traced Back Centuries in the Past—Missing Date of Herodotus Supplied—Uniformity of Nature Proved.*—Now, on the contrary, with the much more precise knowledge we have of the moon's motion, we are in a position to calculate and foretell for a great number of years, and even centuries in advance, not only the general circumstances of eclipses of the moon, but even the detailed course of eclipses of the sun. We can even, by a retrospective examination, give an account of all the circumstances which an ancient eclipse should have presented in such or such a locality, and find the precise date of certain historical events of which the epoch is a subject of discussion. An eclipse of the sun is a veritable rarity for any given place. (Thus, for example, there has not been one at Paris since May 22, 1724; the nineteenth century has not a single one; in the twentieth century, on April 17, 1912, Paris will be just on the limit of totality; but a true total eclipse, of several minutes' duration, will not be seen in the capital of France till August 11, 1999.) Herodotus relates that at the moment of a battle between the Lydians and the Medes a total eclipse of the sun at once stopped the stupefied combatants and put an end to the war. Till recently historians gave various dates for this event, from the year 626 before our era down to the year 583; astronomical calculation, however, proves that this battle took place on May 28 of the year 585 B. C.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 9, p. 182. (A.)

261. ASTRONOMY SUPPOSED EXHAUSTED—*Reenforcement of Physics Has Given It New Youth—The Nature vs. the Movements of the Heavenly Bodies.*—The astronomy so signally promoted by Bessel—the astronomy placed by Comte at the head of the hierarchy of the physical sciences—was the science of the movements of the heavenly bodies. And there were those who began to regard it as a science which, from its very perfection, had ceased to be interesting—whose tale of discoveries was told, and whose further advance must be in the line of minute technical improvements, not of novel and stirring disclosures. But the science of the nature of the heavenly bodies is one only in the beginning of its career. It is full of the audacities, the inconsistencies, the imperfections, the possibilities of youth. It promises everything: it has already performed much; it will doubtless perform much more. The means at its disposal are vast and are being daily augmented.—CLERKE *History of Astronomy*, pt. ii, ch. 1, p. 177. (Bl., 1893.)

262. ASTRONOMY, TRANSFORMATION OF—*A New Epoch—The Manifestation of Universal Life—Peaceful and Glorious Conquests of Science.*—Moreover, astronomy presents us now with one of those radical transformations which form an epoch in the history of the science. It ceases to be a figure and becomes alive. The spectacle of the universe is transfigured before our astonished minds. It is no longer inert bodies rolling in silence in eternal night that the finger of Urania shows us in the depths of the heavens: it is life—life immense, universal, eternal, unfolding itself in waves of harmony out to the inaccessible horizon of an eternal infinite. What marvelous results! What splendors to contemplate! What magnificent fields to traverse! What a series of pictures to admire in these noble and peaceful conquests of the human mind—sublime conquests which cost neither blood nor tears, and where we live in the knowledge of the truth, in the contemplation of the beautiful.—FLAMMARION *Popular Astronomy*, bk. i, ch. 1, p. 3. (A.)

263. ASTRONOMY, UNEXPECTED DEVELOPMENTS IN—*Spectroscope and Camera Supplement Telescope—Man Learns the Nature of Orbs Where He May Never Set Foot.*—The third and last division of celestial science may properly be termed "physical and descriptive astronomy." It seeks to know what the heavenly bodies are in themselves, leaving the How? and the Wherefore? of their movements to be otherwise answered. . . . Inquisitions begun with the telescope have been extended and made effective in unhoped-for directions by the aid of the spectroscope and photographic camera. . . .

The unexpected development of this new physical-celestial science is the leading fact in recent astronomical history. It was out of the regular course of events. In the degree in which it has actually occurred it could certainly not have been foreseen. It was a seizing of the prize by a competitor who had hardly been thought qualified to enter the lists. Orthodox astronomers of the old school looked with a certain contempt upon observers who spent their nights in scrutinizing the faces of the moon and planets rather than in timing their transits; or devoted daylight energies not to reductions and computations, but to counting and measuring spots on the sun. They were regarded as irregular practitioners, to be tolerated perhaps, but certainly not encouraged.—CLERKE *History of Astronomy*, int.. p. 2. (Bl., 1893.)

264. ATHEISM, THE HEART REVOLTS FROM — Our feeling toward atheism goes much deeper than the mere recognition of it as philosophically untrue. The mood in which we condemn it is not at all like the mood in which we reject the corpuscular theory of light. . . . We are wont to look upon atheism with unspeakable horror and loathing. Our moral sense revolts against it no less than our intelligence; and this is because, on its practical side, atheism would remove humanity from its peculiar position in the world, and make it cast in its lot with the grass that withers and the beasts that perish; and thus the rich and varied life of the universe, in all the ages of its wondrous duration, becomes deprived of any such element of purpose as can make it intelligible to us or appeal to our moral sympathies and religious aspirations.—FISKE *Destiny of Man*, ch. 1, p. 13. (H. M. & Co., 1900.)

265. ATHEIST NOT AN IMPOSSIBLE CHARACTER—*Has Become Incapable of Seeing God (Ps. xiv, 1).*—Men tell us sometimes there is no such thing as an atheist. There must be. There are some men to whom it is true that there is no God. They cannot see God because they have no eye. They have only an abortive organ, atrophied by neglect.—DRUMMOND *Natural Law in the Spiritual World*, p. 103. (H. M.)

266. ATMOSPHERE A FATHOMLESS OCEAN—*Perhaps Merging in That of Other Worlds.*—We used to be told that this atmosphere extended forty-five miles above us, but later observation proves its existence at a height of many times this; and a remarkable speculation, which Dr. Hunt strengthens with the great name of Newton, even contemplates it as extending in ever-increasing tenuity until it touches and merges in the atmosphere of other worlds. —LANGLEY *New Astronomy*, ch. 5, p. 136. (H. M. & Co., 1896.)

267. ATMOSPHERE AFFECTED BY VOLCANIC ERUPTION—*Sound-transmission—Waves of Gases Sent Round the World—Air Filled with Rock-dust—Red Sunsets for Two Years.*—The movements which this shock [the eruption of Krakatau in 1883] impressed on the atmosphere were even more remarkable than those which it gave to the sea. The sounds of the explosions were heard for double the distance to which we have any record of their having been audible in previous eruptions. If an eruption of Skaptar in Iceland should be audible at once along our great lakes and upon the Mediterranean, we should have a case of sound-transmission comparable to that in Krakatau in August, 1883. The waves of the air caused by the sudden pressure of the escaping gases rolled around the earth, twice girdling its circumference. Besides the enormous mass of dust which fell upon land and sea within a few hundred miles of the point of explosion, which probably amounted in bulk to as much as twelve cubic miles, an unknown amount of the more finely comminuted rock remained for a long time suspended in the atmosphere and was floated over all parts of the earth's surface, giving to the sky at morning and evening the memorable ruddy glow it presented in the two years following the eruption.—SHALER *Aspects of the Earth*, p. 75. (S., 1900.)

268. ATMOSPHERE A TRAP FOR SUNBEAMS—*Nearness of the Sun Not the Sole Consideration—Saturn and Mercury.*—The cold of outer space can only be estimated, in view of recent observations, as at least four hundred degrees Fahrenheit below zero (mercury freezes at thirty-nine degrees below), and it is the sun which makes up the difference . . . to us, but indirectly, and not in the way that we might naturally think, and have till very lately thought; for our atmosphere has a great deal to do with it beside the direct solar rays, allowing more to come in than to go out, until the temperature rises very much higher than it would were there no air here. Thus, since it is this power in the atmosphere of storing the heat which makes us live, no less than the sun's rays themselves, we see how the temperature of a planet may depend on considerations quite beside its distance from the sun; and when

we discuss the possibility of life in other worlds we shall do well to remember that Saturn may be possibly a warm world, and Mercury conceivably a cold one.—LANGLEY *New Astronomy*, ch. 5, p. 136. (H. M. & Co., 1896.)

269. ATMOSPHERE A VAST HYDRO-ELECTRIC MACHINE—*Friction a General Source of Electricity—Air and Earth Mutually Electrified.*—It has been found that friction is a far more general source of electricity than was at first believed. In fact, electrical phenomena appear to be a constant result of friction, whatever may be the nature of the substances rubbed. Thus it is developed by blowing air over glass. . . . When, now, we consider that the air is always rubbing over the surface of the earth, at times with great rapidity, we shall not be surprised to learn that both bodies are constantly in an electrified condition, the earth being generally charged negatively and the atmosphere positively. Even in fair weather it is always possible to detect the presence of free electricity in the atmosphere; and during a storm, when clouds filled with drops of water are hurried over the surface, grinding against the hills and the trees, or against each other, the atmosphere becomes a vast hydro-electric machine, whose sparks are the lightning and the noise of whose discharges the thunder.—COOKE *Religion and Chemistry*, ch. 2, p. 59. (S., 1891.)

270. ATMOSPHERE, MAGNETIC—*Aura around Electrical Conductor.*—The electrical current is competent to produce effects not merely in its channel or conductor—like water turning a wheel—but to influence bodies entirely outside of that channel. It causes, around its conductor, a peculiar aura or atmosphere like that around the poles of a magnet, but differing from the latter as a whirlwind differs from a steady gale. It converts the conductor into a magnet, which, like other magnets, is capable of influencing magnetic bodies to become magnets. It also converts magnetic bodies, around which the conductor is wound, into magnets; and a bar of iron in this way is given all the properties which it would have were it normally and naturally a magnet, or piece of lodestone.—PARK BENJAMIN *Age of Electricity*, ch. 6, p. 87. (S., 1897.)

271. ——— ——— *Aura or Field of Force around the Poles of a Magnet.*—It appears, therefore, that around the pole of a magnet exists this strange atmosphere—a so-called "field of force," in which exist strains and pulls and pushes as if a host of infinitesimal beings were at work seizing upon the filings, and arranging them to make them accommodate themselves to this new condition of affairs. And the result of it all is, that we recognize seeming lines of force radiating from the pole. It is a wonderful atmosphere, that magnetic field. We have only to move a piece of iron in it, in a peculiar way, to make speech heard miles distant, or to produce the light which is weaker only than the sun in power; and what still stranger things may yet be done no one knows.—PARK BENJAMIN *Age of Electricity*, ch. 6, p. 75. (S., 1897.)

272. ATMOSPHERE OF DEATH—*A Barbarous Experiment—Suffocation of a Dog—Gas Bailed Out Extinguishes Candle.*—Many natural springs of carbonic acid have been discovered, one of which I should like to introduce to your notice. In the neighborhood of the city of Naples there is a cave called the Grotto del Cane, a name given to it for a curious and culpable reason. During one of the eruptions of Vesuvius I paid a visit, in company with two friends, to Naples, and went to see, among the other sights of that wonderful region, the Grotto of the Dog. At a place adjacent we met a guide and some other visitors. At the heels of the guide was a timid little quadruped, which, for the time being, was the victim that gave the cave its name. We could walk into the cave without inconvenience, knowing, at the same time, from the descriptions we had heard and read, that our feet were plunged in a stream of heavy carbonic acid flowing along the bottom of the cave. The poor little dog, much against its will, was brought into the grotto. The stream of carbonic acid was not deep enough to cover the animal; its master, accordingly, pressed its head under the suffocating gas. It struggled for a time, but soon became motionless—apparently lifeless. Taken into the air outside, through a series of convulsions painful to look upon, it returned to life.

The experiment is a barbarous one, and ought not to be tolerated. There are many ways of satisfying the curious without cruelty to the dog. I made the following experiment, which seemed to surprise the bystanders. Placing a burning candle near the bottom of my hat, in the open air outside the cave, I borrowed a cap, and by means of it ladled up the heavy gas. Pouring it from the cap into the hat, the light was quenched as effectually as if water had been poured upon it. Made with glass jars instead of hats, this is a familiar laboratory experiment.—TYNDALL *New Fragments*, p. 338. (A., 1897.)

273. ATMOSPHERE OF THE SUN—*Far Exceeds the Central Mass—Main Body of the Luminary Commonly Unseen.*—What we see of the sun under ordinary circumstances is but a fraction of his total bulk. While by far the greater portion of the solar mass is included within the photosphere—the blazing cloud-layer, which seems to form the sun's true surface, and is the principal source of his light and heat—yet the larger portion of his volume lies without, and constitutes an atmosphere

whose diameter is at least double, and its bulk therefore sevenfold that of the central globe.—YOUNG *The Sun*, ch. 6, p. 191. (A., 1898.)

274. ATMOSPHERE ONCE A SOURCE OF ERROR—*Combustion Not Understood till a Century Ago.*—At first sight chemical processes are frequently very obscure, and one great reason is, that we live in an atmosphere which is a mixture of two invisible aeriform substances, named nitrogen gas and oxygen gas; and these substances, especially the last, are constantly entering as factors into chemical processes without our noticing the circumstance; and, again, the products of such processes, when aeriform, often escape notice by mingling with the great volume of the air. Now, that we are on our guard, we are seldom deceived by the intervention of the atmosphere; but in former times, when the qualities and relations of aeriform bodies were little known, so great was the obscurity thus caused that even the familiar processes of combustion have not been understood until within a century.—COOKE *New Chemistry*, lect. 4, p. 87. (A., 1899.)

275. ATMOSPHERE, POSSIBLE, OF THE MOON—Upon the whole, then, there may (and there should) exist on the moon an atmosphere of feeble density, and probably of a composition very different from ours. Perhaps there may also exist certain liquids, such as water, but in a minimum quantity. If it had no air at all there could not exist a single drop of water, seeing that it is the atmospheric pressure which maintains water in the liquid state, and that without it all water would immediately evaporate. It is possible, after all, that the lunar hemisphere which we never see may be richer in fluids than the visible one. But we see that in any case it would be contrary to the real interpretation of facts to assert, as is too often done, that there is absolutely no atmosphere nor any liquid or fluid on the surface of the moon.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 4, p. 140. (A.)

276. ATMOSPHERE SEPARATED INTO STRATA WOULD DESTROY PITCH OF SOUNDS—*Music Depends on Chemical Law—Diffusion of Gases.*—As the air is now constituted, there is a constancy of pitch, however far sound travels. Any tone once generated remains the same tone until it dies away. Its degree of loudness alters in proportion to the distance of the listener, but the pitch is constant. Were it not, however, for this law of diffusion—were the atmosphere not perfectly homogeneous, and the gases of which it consists even partially separated—there would have been a very different result. The constancy of pitch could no longer have been depended upon. The sound as it traveled would vary its pitch with the ever-varying medium through which it passed, and would arrive at the ear with a tone entirely different from that with which it started. Nor would it require any great difference in the medium to produce a sensible result and to confuse all those delicate differences of pitch on which the whole art of music depends. Whenever, therefore, you may be next enjoying the grand Pastoral Symphony of Beethoven or the Requiem of Mozart, recall the careful adjustment of forces by which alone these magnificent creations of genius were rendered possible, and you cannot fail to recognize in this simple law of Nature the same hand that first strung the lyre and made the soul of man responsive to its seven notes.—COOKE *Religion and Chemistry*, ch. 3, p. 76. (A., 1897.)

277. ATOMS FALL TOGETHER IN COMBUSTION—The burning of charcoal in oxygen is an old experiment, but it has now a significance beyond what it used to have; we now regard the act of combination on the part of the atoms of oxygen and coal as we regard the clashing of a falling weight against the earth. The heat produced in both cases is referable to a common cause. A diamond, which burns in oxygen as a star of white light, glows and burns in consequence of the falling of the atoms of ogygen against it.—TYNDALL *Fragments of Science*, vol. i, ch. 16, p. 372. (A., 1897.)

278. ATOMS, POLARITY OF—*Every Fragment of the Magnet Retains Its Poles.*—What, then, will occur if we break this magnet in two at the center? Shall we obtain two magnets, each with a single pole? No; each half is in itself a perfect magnet, possessing two poles. This may be proved by breaking something of less value than the magnet—the steel of a lady's stays, for example, hardened and magnetized. It acts like the magnet. When broken, each half acts like the whole; and when these parts are again broken we have still the perfect magnet, possessing, as in the first instance, two poles. Push your breaking to its utmost sensible limit, you cannot stop there. The bias derived from observation will infallibly carry you beyond the bourn of the senses, and compel you to regard this thing that we call magnetic polarity as resident in the ultimate particles of the steel. You come to the conclusion that each atom of the magnet is endowed with this polar force. —TYNDALL *Lectures on Light*, lect. 3, p. 97. (A., 1898.)

279. ATOMS, THEIR NUMBER AND WEIGHT—*Heat a Peculiar Form of Atomic Motion.*—Chemistry teaches that heat is directly related to the atoms of matter. Atoms of different substances differ greatly in weight. For instance, the hydrogen atom is the unit of atomic weight, because it is the lightest of all of them. Taking the hydrogen atom as the unit, in round numbers the iron atom weighs as much as 56 atoms

of hydrogen, copper a little over 63, silver 108, gold 197. Heat acts upon matter according to the number of atoms in a given space, and not as its weight. Knowing the relative weights of the atoms of the different metals named, it would be possible to determine by weight the dimensions of different pieces of metal so that they will contain an equal number of atoms. If we take pieces of iron, copper, silver, and gold, each of such weight as that all the pieces will contain the same number of atoms, and subject them to heat till all are raised to the same temperature, it will be found that they have all absorbed practically the same quantity of heat without regard to the different weights of matter. It will be observed that the piece of silver, for instance, will have to weigh nearly twice as much as the iron in order to contain the same number of atoms, but it will absorb the same amount of heat as the piece of iron containing the same number of atoms if both are raised to the same temperature. In view of the above fact it seems that heat acts especially upon the atoms of matter and is a peculiar form of atomic motion. Heat is one kind of motion of the atoms, while electricity may be another form of motion of the same. The two motions may be carried on together.—ELISHA GRAY *Nature's Miracles*, vol. iii, ch. 26, p. 42. (F. H. & H., 1900.)

280. ATOMS THE ULTIMATE ELEMENTS OF CHEMISTRY—*Atomic Evolution.*—If the union of atoms is attended with an ever-increasing evolution of heat as they press together into closer and closer associations, we should naturally expect that the effect of increasing temperature would be to part the atoms; and as we study the phenomena of disassociation we are led to the latest conception of chemical philosophy, that of a condition of disassociated atoms out of which the material universe has been developed. Such isolated atoms are for the present at least the ultimate elements of chemistry, and before reaching this condition all qualities which distinguish substances disappear except only a definite mass whose rhythmic pulsations the spectroscope may reveal. As out of such a primal chaotic condition molecular structures were evolved, the qualities of substances appeared, and the energy of nature was awakened. To discover the laws of this evolution so as to follow its various steps, and be able to predict the results under given conditions, is the future work of chemistry.—COOKE *The New Chemistry*, int., p. 17. (A., 1899.)

281. ATROPHY OF EYES DUE TO DISUSE—*Cave-fishes.*—But there is much in the history of the development of animals that seems to lead to the belief that eventually modifications may be due in part to acts of representatives of the phylum to which they belong. It is difficult to believe that some structural features are simply the result of natural selection operating on chance variations. An application of the doctrine of chances to some such cases appears to be adverse to the conception that they represent the influence of natural selection unaided.

A feature characteristic of most cave animals of widely diverse groups and classes is the atrophy of the eyes, and it seems to be most logical to attribute this to disuse of those organs in remote progenitors, and to assume that the atrophy may have resulted from a failure of nourishment by the nutrient fluid of the organs on account of the loss of functional activity, rather than to selection by nature of forms with successively diminishing eyes. The presence of eyes in most cases certainly would scarcely be an element of disadvantage to animals, and it may be allowable to invoke some other agency than chance selection. We may be justified in postulating that the continuous disuse of the organs would in time react on the nutrition of the parts affected, and finally atrophy or disappearance would result. Like explanation would be applicable to the innumerable cases of atrophy of parts known to the naturalist.—GILL *Proc. Am. Assoc. for the Advancement of Science*, vol. xlvi. (1897.)

282. ATROPHY OF MENTAL POWERS THROUGH DISUSE—*Darwin's Distaste for Poetry.*—There is a passage in Darwin's short autobiography which has been often quoted, and which, for the sake of its bearing on our subject of habit, I must now quote again. Darwin says: "Up to the age of thirty or beyond it, poetry of many kinds gave me great pleasure; and even as a schoolboy I took intense delight in Shakespeare, especially in the historical plays. I have also said that pictures formerly gave me considerable and music very great delight. But now for many years I cannot endure to read a line of poetry. I have tried lately to read Shakespeare, and found it so intolerably dull that it nauseated me. I have also almost lost my taste for pictures or music. . . . My mind seems to have become a kind of machine for grinding general laws out of large collections of facts; but why this should have caused the atrophy of that part of the brain alone, on which the higher tastes depend, I cannot conceive. . . . If I had to live my life again, I would have made a rule to read some poetry and listen to some music at least once every week; for perhaps the parts of my brain now atrophied would thus have been kept alive through use. The loss of these tastes is a loss of happiness, and may possibly be injurious to the intellect, and more probably to the moral character, by enfeebling the emotional part of our nature."—JAMES *Talks to Teachers*, ch. 8, p. 71. (H. H. & Co., 1900.)

283. ATTENTION BRIEF IF VOLUNTARY—*Longer Sustained if Passive—Constant Change of Object—Variety Needed.*—There is no such thing as voluntary attention sustained for more than a few seconds at a time. What is called sustained voluntary attention is a repetition of successive efforts which bring back the topic to the mind. The topic once brought back, if a congenial one, develops; and if its development is interesting it engages the attention passively for a time. . . . This passive interest may be short or long. As soon as it flags, the attention is diverted by some irrelevant thing, and then a voluntary effort may bring it back to the topic again; and so on, under favorable conditions, for hours together. During all this time, however, note that it is not an identical object in the psychological sense, but a succession of mutually related objects, forming an identical topic only, upon which the attention is fixed. No one can possibly attend continuously to an object that does not change.—JAMES *Psychology*, vol. i, ch. 11, p. 420. (H. H. & Co., 1899.)

284. ATTENTION, FIXATION OF—*The Microscopist's Purposed Blindness.*—The practised microscopist, whilst applying one of his eyes to his instrument, and determinedly giving his whole attention to the visual picture he receives through it, can keep his other eye open without being in the least disturbed by the picture of the objects on the table, which must be formed upon its retina, but which he does not see unless their brightness should make him perceive them.—CARPENTER *Mental Physiology*, ch. 3, p. 135. (A., 1900.)

285. ATTENTION IN LISTENING—*Ability to Fix on Particular Part in a Harmony.*—In the act of listening we are not only distinctly conscious of sounds so faint that they would not excite our notice but for the volitional direction of the attention, but we can single out these from the midst of others by a determined and sustained effort, which may even make us quite unconscious of the rest so long as that effort is kept up. Thus a person with a practised "musical ear" (as it is commonly but erroneously termed, it being not the ear, but the brain, which exerts this power), whilst listening to a piece of music played by a large orchestra, can single out any one part in the harmony and follow it through all its mazes; or can distinguish the sound of the weakest instrument in the whole band and follow its strain through the whole performance. And an experienced conductor will not only distinguish when some instrumentalist is playing out of tune, but will at once single out the offender from the midst of a numerous band.—CARPENTER *Mental Physiology*, ch. 3, p. 137. (A., 1900.)

286. ATTENTION, POWER OF, ATTRIBUTED TO EARTHWORMS—*Apparent Evidence of Mental Preoccupation.*—When a worm is suddenly illuminated and dashes like a rabbit into a burrow—to use the expression employed by a friend—we are at first led to look at the action as a reflex one. The irritation of the cerebral ganglia appears to cause certain muscles to contract in an inevitable manner, independently of the will or consciousness of the animal, as if it were an automaton. But the different effect which a light produced on different occasions, and especially the fact that a worm when in any way employed and in the intervals of such employment, whatever set of muscles and ganglia may then have been brought into play, is often regardless of light, are opposed to the view of the sudden withdrawal being a simple reflex action. With the higher animals, when close attention to some object leads to the disregard of the impressions which other objects must be producing on them, we attribute this to their attention being then absorbed; and attention implies the presence of a mind. Every sportsman knows that he can approach animals whilst they are grazing, fighting, or courting, much more easily than at other times. The state, also, of the nervous system of the higher animals differs much at different times; for instance, a horse is much more readily startled at one time than at another. The comparison here implied between the actions of one of the higher animals and of one so low in the scale as an earthworm may appear far-fetched, for we thus attribute to the worm attention and some mental power: nevertheless I can see no reason to doubt the justice of the comparison.—DARWIN *Formation of Vegetable Mould*, ch. 1, p. 7. (Hum., 1887.)

287. ATTENUATION OF VIRULENCE OF BACTERIA—*Pasteur's Method—Protection by Weakening the Enemy.*—It was pointed out by some of the pioneer bacteriologists that the function of bacteria suffered under certain circumstances a marked diminution in power. Later workers found that such a change might be artificially produced. Pasteur introduced the first method, which was the simple one of allowing cultures to grow old before subculturing. Obviously a pure culture cannot last forever. To maintain the species in characteristic condition it is necessary frequently to subculture upon fresh media. If this simple operation be postponed as long as possible consistent with vitality, and then performed, it will be found that the subculture is attenuated, *i. e.*, weakened. Another mode is to raise the pure culture to a temperature approaching its thermal death-point. A third way of securing the same end is to place it under disadvantageous external circumstances, for example a too alkaline or too acid medium. A fourth,

but rarely necessary, method is to pass it through the tissues of an insusceptible animal. Thus we see that, whilst the favorable conditions which we have considered afford full scope for the growth and performance of functions of bacteria, we are able by a partial withdrawal of these, short of that ending fatally, to modify the character and strength of bacteria.—NEWMAN *Bacteria*, ch. 1, p. 36. (G. P. P., 1899.)

288. ATTRACTION CONSTANT, HOWEVER LONG RESTRAINED—The day was fading and the deeper glacier pools were shaded by their icy banks. Through the shadowed water needles of ice were darting; all day long the molecules had been kept asunder by the antagonistic heat; their enemy is now withdrawn, and they lock themselves together in a crystalline embrace.—TYNDALL *Hours of Exercise in the Alps*, ch. 6, p. 74. (A., 1898.)

289. AURORA MAY ENVELOP THE EARTH—*Australis Responds to Borealis.*—It would even seem that this simultaneity of the aurora borealis and australis is the rule and not the exception. Data with regard to the southern hemisphere are often wanting, yet we possess an uninterrupted series of eight years of observations taken at Hobart Town in Tasmania, from 1841 to 1848, during which thirty-four auroras were reckoned. Now, every time that an aurora was seen at Hobart Town an aurora borealis was observed in the northern hemisphere; or, at least, if it were daytime in Europe, there were those important magnetic perturbations which accompany polar auroras.

If it be remembered that the presence of the sun above the horizon prevents a given aurora from being seen over half the surface of the globe, and if we remark that, in the cases cited above, the aurora was seen in the whole of that part of the mean latitudes of the globe where it was night at the time of its appearance, it will not seem unreasonable to admit that at certain moments the lights of the double polar aurora may entirely envelop the earth, with the exception of an equatorial zone of a width of about forty degrees.—ANGOT *Aurora Borealis*, ch. 4, p. 55. (A., 1897.)

290. AUTHORITY A HINDRANCE TO INVESTIGATION—*Werner's Pupils Too Eager to Maintain His Views—Travel Needed for Broad Views of the Universe.*—Werner had a great antipathy to the mechanical labor of writing, and, with the exception of a valuable treatise on metalliferous veins, he could never be persuaded to pen more than a few brief memoirs, and those containing no development of his general views. Altho the natural modesty of his disposition was excessive, approaching even to timidity, he indulged in the most bold and sweeping generalizations, and he inspired all his scholars with a most implicit faith in his doctrines. Their admiration of his genius, and the feelings of gratitude and friendship which they all felt for him, were not undeserved; but the supreme authority usurped by him over the opinions of his contemporaries was eventually prejudicial to the progress of the science; so much so as greatly to counterbalance the advantages which it derived from his exertions. If it be true that delivery be the first, second, and third requisite in a popular orator, it is no less certain that to travel is of first, second, and third importance to those who desire to originate just and comprehensive views concerning the structure of our globe. Now Werner had not traveled to distant countries; he had merely explored a small portion of Germany, and conceived, and persuaded others to believe, that the whole surface of our planet, and all the mountain chains in the world, were made after the model of his own province. It became a ruling object of ambition in the minds of his pupils to confirm the generalizations of their great master, and to discover in the most distant parts of the globe his "universal formations," which he supposed had been each in succession simultaneously precipitated over the whole earth from a common menstruum, or "chaotic fluid." It now appears that the Saxon professor had misinterpreted many of the more important appearances even in the immediate neighborhood of Freiberg.—LYELL *Principles of Geology*, bk. i, ch. 4, p. 47. (A., 1854.)

291. AUTHORITY OF MOTHERHOOD—There is at least one authority the rightfulness of which is not a question, but a fact. All men are born of parents. All men, moreover, are born in a condition of utter helplessness and of absolute dependence. . . . It is a dependence arising out of conditions full to overflowing of all the elements to which the sentiment of moral obligation is necessarily and intuitively attached. It is the least and lowest of these elements that at the breasts of its mother an infant first satisfies its hunger and its thirst. Other elements follow in an ascending order. In the arms of its mother it feels the first sense of rest, and the first ideas of refuge and of protection. In the voice of its mother it hears the first expressions of love, and makes the first responses which that love demands. In the smile of its mother it first finds the great gift of laughter. In the eyes of its mother it has its first look into the mirror of another spirit, and feels the answering tides which are stirring within its own. These are but a part of the great claim, accumulating with the hours and days, upon which the authority of a mother rests. And so it comes to pass that the rightfulness of that authority is by the necessities of nature recognized from the first, and when its voice is issued in command, the duty of obedience is felt and known. As a matter of fact, therefore,

and not at all as a matter of question or of doubt, our first conception of duty, or of moral obligation, is necessarily and universally attached to such acts as are in conformity with the injunctions of this first and most indisputable of all authorities.—ARGYLL *Unity of Nature,* ch. 9, p. 210. (Burt.)

292. AUTHORITY USED TO MAINTAIN ERROR—*Dispute over Nature of Light—Conflict of Theories.*—After philosophers had become aware of the manner in which sound was produced and transmitted, analogy led some of them to suppose that light might be produced and transmitted in a somewhat similar manner. And perhaps, in the whole history of science, there was never a question more hotly contested than this one. Sir Isaac Newton . . . supposed light to consist of minute particles, darted out from luminous bodies. Huygens, the contemporary of Newton, found great difficulty in admitting this cannonade of particles; or in realizing that they could shoot with inconceivable velocity through space, and yet not disturb each other. This celebrated man entertained the view that light was produced by vibrations similar to those of sound. Euler supported Huygens. . . .

The authority of Newton bore these men down, and not until a man of genius within these walls took up the subject had the theory of undulation any chance of coping with the rival theory of emission. To Dr. Thomas Young, formerly Professor of Natural Philosophy in the Royal Institution, belongs the honor of stemming this tide of authority, and of establishing, on a safe basis, the undulatory theory of light. Great things have been done in this edifice; but scarcely a greater thing than this.—TYNDALL *Heat a Mode of Motion,* lect. 10, p. 274. (A., 1900.)

293. AUTOMATISM IMPLIES DESIGN—*Mind behind Machine.*—The automatic theory would seem to be one which can least of all dispense with design, since, either in the literal or current sense of the word, undesigned automatism is, as near as may be, a contradiction in terms. As the automaton man constructs manifests the designs of its maker and mover, so the more efficient automata which man did not construct would not legitimately suggest less than human intelligence. And so all adaptations in the animal and vegetable world which irresistibly suggest purpose (in the sense now accepted) would also suggest design, and, under the law of parsimony, claim to be thus interpreted, unless some other hypothesis will better account for the facts.—ASA GRAY *Darwiniana,* art. 13, p. 360. (A., 1889.)

294. AUTOMATISM LABORIOUSLY ACQUIRED—*The Beginner on the Violin.*—"When one begins to play on the violin, to keep him from raising his right elbow in playing, a book is placed under his right armpit, which he is ordered to hold fast by keeping the upper arm tight against his body. The muscular feelings, and feelings of contact connected with the book, provoke an impulse to press it tight. But often it happens that the beginner, whose attention gets absorbed in the production of the notes, lets drop the book. Later, however, this never happens; the faintest sensations of contact suffice to awaken the impulse to keep it in its place, and the attention may be wholly absorbed by the notes and the fingering with the left hand. The simultaneous combination of movements is thus in the first instance conditioned by the facility with which in us, alongside of intellectual processes, processes of inattentive feeling may still go on."—(Schneider, "Der menschliche Wille.")—JAMES *Psychology,* vol. i, ch. 4, p. 119. (H. H. & Co., 1899.)

295. AUTOMATISM OF MUSICIAN—*Muscles Respond Unconsciously to Sight or Sound.*—Thus a musical performer will play a piece which has become familiar by repetition, whilst carrying on an animated conversation, or whilst continuously engrossed by some train of deeply interesting thought; the accustomed sequence of movements being directly prompted by the sight of the notes, or by the remembered succession of the sounds (if the piece is played from memory), aided in both cases by the guiding sensations derived from the muscles themselves. But further, a higher degree of the same "training" (acting on an organism specially fitted to profit by it) enables an accomplished pianist to play a difficult piece of music at sight; the movements of the hands and fingers following so immediately upon the sight of the notes that it seems impossible to believe that any but the very shortest and most direct track can be the channel of the nervous communication through which they are called forth.—CARPENTER *Mental Physiology,* ch. 5, p. 217. (A., 1900.)

296. AUTOMATISM, THEORY OF, DESTROYS RESPONSIBILITY—*Drunkard Held Blameless—Conqueror of Temptation Allowed No Merit.*—On the automatist theory, a drunkard who deserts a comfortable home for the taproom (I make large allowance for those who have uncomfortable homes), who neglects an attached wife and loving children for the society of profligates, and who, with ample means of higher enjoyment, surrenders himself without a struggle to the allurements of sensual pleasure, and at last renders himself amenable to the law by fatal outrage on the patient wife who has long borne with his brutality, is no more a subject of moral reprobation than poor Hartley Coleridge, who, when he strayed from the loving care of his friends, would be found in the parlor of some rural

public house, delighting the rustics with his wonderful stories, and indulging to his heart's content in the unlimited beer which the publican was only too glad to allow him. When, on the other hand, the subject of a strong hereditary alcoholic craving maintains a daily conflict with his tempter, uses every means he can think of to avoid or weaken its seductions, puts forth all his energy in resisting them, and, through occasional failures, comes off on the whole victorious, the consistent automatist can have no other approbation to bestow upon him than that which he would accord to a self-governing steam-engine, or a compensation balance watch.—CARPENTER *Mental Physiology,* pref., p. 42. (A., 1900.)

297. AUTOMATON THEORY AN IMPERTINENCE — My conclusion is that to urge the automaton theory upon us, as it is now urged, on purely a priori and quasi-metaphysical grounds, is an unwarrantable impertinence in the present state of psychology.—JAMES *Psychology,* vol. i, ch. 5, p. 138. (H. H. & Co., 1899.)

298. AVALANCHE OF STONES—*Abasing That Which Is High—Ceaseless Leveling Action of Denuding Forces.*—By this action the hardest and most solid rock-masses are reduced to a state of complete disintegration, certain of their ingredients undergoing decomposition, and the cementing materials which hold their particles together being removed in a state of solution. In the higher regions of the atmosphere this work of rock-disintegration proceeds with the greatest rapidity; for there the chemical action is reenforced by the powerful mechanical action of freezing water. On high mountain peaks the work of breaking up rock-masses goes on at the most rapid rate, and every craggy pinnacle is swathed by the heaps of fragments which have fallen from it. The Alpine traveler justly dreads the continual fusillade of falling rock-fragments which is kept up by the ever-active power of the frost in these higher regions of the atmosphere; and fears lest the vibrations of his footsteps should loosen, from their position of precarious rest, the rapidly accumulating piles of detritus. No mountain peak attains to any very great elevation above the earth's surface, for the higher we rise in the atmosphere the greater is the range of temperature and the more destructive are the effects of the atmospheric water.—JUDD *Volcanoes,* ch. 10, p. 283. (A., 1899.)

299. ——— ——— *Mountainside Raked as by Cannon-shot.*—While we stood pondering here [on the side of the Weisshorn], a deep and confused roar attracted our attention. From a point near the summit of the Weisshorn a rock had been discharged down a dry couloir, raising a cloud of dust at each bump against the mountain. A hundred similar ones were immediately in motion, while the spaces between the larger masses were filled by an innumerable flight of smaller stones. Each of them shook its quantum of dust in the air, until finally the avalanche was enveloped in a cloud. The clatter was stunning, for the collisions were incessant. Black masses of rock emerged here and there from the cloud, and sped through the air like flying fiends. Their motion was not one of translation merely, but they whizzed and vibrated in their flight as if urged by wings. The echoes resounded from side to side, from the Schallenberg to the Weisshorn and back, until finally, after many a deep-sounding thud in the snow, the whole troop came to rest at the bottom of the mountain. This stone avalanche was one of the most extraordinary things I had ever witnessed, and in connection with it I would draw the attention of future climbers of the Weisshorn to the danger which would infallibly beset any attempt to ascend it from this side, except by one of its *arêtes.* At any moment the mountainside may be raked by a fire as deadly as that of cannon.—TYNDALL *Hours of Exercise in the Alps,* ch. 9, p. 110. (A., 1898.)

300. AWAKENING DETERMINED BY INTEREST—*Hearing of One's Own Name.*—The awakening power of sensory impressions is greatly modified by our habitual state of mind in regard to them. Thus most sleepers are awoke by the sound of their own names uttered in a low tone, when it requires a much louder sound of a different description to produce any manifestation of consciousness. The same thing is seen in comatose states, a patient being often found capable of being momentarily aroused by shouting his name into his ear, when no other sound produces the least effect.—CARPENTER *Mental Physiology,* bk. ii, ch. 15, p. 581. (A., 1900.)

301. AWAKENING DUE TO EXPECTANT ATTENTION — But it is not requisite that the sensory impression should be one habitually attended to during the waking hours, for it is generally sufficient to produce the effect, that the attention should have been strongly fixed upon it, previously to the access of the sleep, as one at which the slumberer is to be aroused. Thus the traveler who requires to set forth upon his journey at an early hour in the morning, and has given directions to be called accordingly, is awakened by a gentle tap at the door of his chamber, altho he may have previously slept through a succession of far louder noises with which he had no concern.—CARPENTER *Mental Physiology,* bk. ii, ch. 15, p. 583. (A., 1900.)

302. AX, THE CHIEF WEAPON OF PRIMITIVE MAN—*Labor and Skill in Making of Axes from Stone.*—The ax was preeminently the implement of antiquity. It was used in war and in the chase, as well

as for domestic purposes, and great numbers have been found, especially at Wangen (Lake of Constance) and Concise (Lake of Neufchâtel). With a few exceptions they are small, especially when compared with the magnificent specimens from Denmark; in length they varied from one to six inches, while the cutting edge had generally a width of from fifteen to twenty lines. Flint was sometimes used, and nephrite or jade in a few cases, but serpentine and diorite were the principal materials. Most of the larger settlements were evidently manufacturing places, and many spoiled pieces and half-finished specimens have been found. After having chosen a stone, the first step was to reduce it by blows with a hammer to a suitable size. Then grooves were made artificially, which must have been a very tedious and difficult operation when flint knives, sand, and water were the only available instruments. Having carried the grooves to the required depth, the projecting portions were removed by a skilful blow with a hammer, and the implement was then sharpened and polished on blocks of sandstone.—AVEBURY *Prehistoric Times*, ch. 6, p. 180. (A., 1900.)

303. BACTERIA CAPTURE NITROGEN FOR HIGHER ORGANISMS — *The Nitrifying Bacteria.*—The third group of micro-organisms connected with the soil exist in groups and colonies situated inside the nodules appearing, under certain circumstances, on the rootlets of the pea, bean, and other *Leguminosæ*. It was Hellriegel and Wilfarth who first pointed out that, altho the higher chlorophyllaceous plants could not directly obtain or utilize free nitrogen, some of them at any rate could acquire nitrogen brought into combination under the influence of bacteria. Hellriegel found that the graminaceous, polygonaceous, cruciferous, and other orders depended upon combined nitrogen supplied within the soil, but that the *Leguminosæ* did not depend entirely upon such supplies.—NEWMAN *Bacteria*, ch. 5, p. 163. (G. P. P., 1899.)

304. BACTERIA, UNIVERSAL PRESENCE OF—*In Earth, Air, and Water. Everywhere.*—There are no other plants or animals so universally found in nature as the bacteria. It is this universal presence, together with their great powers of multiplication, which renders them of so much importance in nature. They exist almost everywhere on the surface of the earth. They are in the soil, especially at its surface. . . . They are in all bodies of water, both at the surface and below it. They are found at considerable depths in the ocean. They are in streams of running water in even greater quantity than in standing water.—CONN *Story of Germ Life*, ch. 1, p. 38. (A., 1900.)

305. ——— *Microscopic Organisms Dormant in Dust.*—Wherever on the face of nature there is a lodging-place for dust there will be found bacteria. In most of these localities they are dormant, or at least growing only a little. The bacteria . . . in pure water multiply very little. When dried as dust they are entirely dormant. But each individual bacterium or spore has the potential power of multiplication, and as soon as it by accident falls upon a place where there is food and moisture it will begin to multiply. Everywhere in Nature, then, exists this group of organisms with its almost inconceivable power of multiplication, but a power held in check by lack of food. Furnish them with food and their potential powers become actual.—CONN *Story of Germ Life*, ch. 1, p. 38. (A., 1900.)

306. BACTERIOLOGY, PRACTICAL IMPORTANCE OF—Municipalities are expending public moneys in water analysis, in the examination of milk, in the inspection of cows and dairies, in the bacterial treatment of sewage, and in disinfection and other branches of public health administration. Again, the newly formed National Association for the Prevention of Tuberculosis, our increasing colonial possessions with their tropical diseases, even medical science itself, which is year by year becoming more preventive, make an increasing claim upon public opinion. The successful accomplishment and solution of these questions depend in a measure upon an educated public opinion respecting the elements of bacteriology. Recently it was urged [in the *Contemporary Review*, Nov., 1897] that "the first elements of bacteriology should be shadowed forth in the primary school." This course was advised owing to such knowledge being of value to those engaged in dairying. As we shall point out at a later stage, many of the undesirable changes occurring in milk are due to bacteria, even as the success of the butter and cheese industries depends on the use and control of the fermentative processes due to their action. Much of the uncertainty attending the manufacture of dairy products can only be abolished by the careful application of some knowledge of the flora of milk.—NEWMAN *Bacteria*, int., p. 12. (G. P. P., 1899.)

307. BALANCE OF FORCES ON OUR GLOBE—*The Earth a Delicately Adjusted Machine—Contrast of the Moon.*—In our nearest neighbor among the planets—the moon—the telescope has revealed to us the existence of a globe, in which the internal forces have not been checked and controlled by the operation of any external agencies—for the moon appears to be destitute of both atmosphere and water. Under these circumstances we find its surface, as we might expect, to be composed of rocks which appear to be entirely of igneous origin; the mountain masses, unworn by rain or frost, river or glacier, being of most prodigious dimensions as compared with those of our own globe, while no features at all resembling

valleys, or plains, or alluvial flats are anywhere to be discerned upon the lunar surface. But by the admirable balancing of the external and internal forces on our own globe, the conditions necessary to animal and vegetable existence are almost constantly maintained, and those interruptions of such conditions, produced by hurricanes and floods, by volcanic outbursts and earthquakes, may safely be regarded as the insignificant accidents of what is, on the whole, a very perfectly working piece of machinery.—JUDD *Volcanoes*, ch. 10, p. 305. (A., 1899.)

308. BALANCE OF HAPPINESS IN THE ANIMAL WORLD—On the whole, then, we conclude that the popular idea of the struggle for existence entailing misery and pain on the animal world is the very reverse of the truth. What it really brings about is the maximum of life and of the enjoyment of life with the minimum of suffering and pain. Given the necessity of death and reproduction—and without these there could have been no progressive development of the organic world—and it is difficult even to imagine a system by which a greater balance of happiness could have been secured.—WALLACE *Darwinism*, ch. 2, p. 27. (Hum., 1889.)

309. BARBARIANS OF ANCIENT EUROPE—*Use of Iron Known by Them.*—The soldiers of Brennus were provided with iron swords, and when the armies of Rome brought the civilization of the South into contact with that of the North they found iron already well known to, and in general use among, their new enemies. Nor is there any reason to suppose that arms of bronze were also at that time still in use in the North, for, had this been so, they would certainly have been mentioned by the Roman writers; whereas the description given by Tacitus of the Caledonian weapons shows that in his time the swords used in Scotland were made of iron. Moreover, there are several cases in which large quantities of arms belonging to the Roman period have been found together, and in which the arms and implements are all of iron. This argument is in its very nature cumulative, and cannot therefore be fully developed here.—AVEBURY *Prehistoric Times*, ch. 7, p. 8. (A., 1900.)

310. BARBARISM, NURSERIES OF—*The Steppes of Asia Have Sent Destruction to Europe.*—These Mongolian and Tartar Steppes, which are intersected by numerous mountain chains, separate the ancient and long-civilized races of Tibet and Hindustan from the rude nations of Northern Asia. They have also exerted a manifold influence on the changing destinies of mankind. They have inclined the current of population southward, impeded the intercourse of nations more than the Himalayas, or the Snowy Mountains of Sirinagur and Gorka, and placed permanent limits to the progress of civilization and refinement in a northerly direction.

History cannot, however, regard the plains of Central Asia under the character of obstructive barriers alone. They have frequently proved the means of spreading misery and devastation over the face of the earth. Some of the pastoral tribes inhabiting this steppe—the Mongols, Getæ, Alani, and Usfini—have convulsed the world. If in the course of earlier ages the dawn of civilization spread like the vivifying light of the sun from east to west, so in subsequent ages and from the same quarter have barbarism and rudeness threatened to overcloud Europe.—HUMBOLDT *Views of Nature*, p. 4. (Bell, 1896.)

311. BAROMETER, ETHICAL, THE—*Lessons Taught by Statistics of Crime.*—The statistics of crime within a given period registers how the ethical barometer stands in dry figures. The statistics of the cases brought before the law are facts that cannot be shaken—they speak for themselves.—BASTIAN *Allgemeine Grundzüge der Ethnologie.* (Translated for *Scientific Side-Lights.*)

312. BARRENNESS SELF-PERPETUATING—*Cause and Effect Reciprocal—Clouds Wait Vainly over the Sahara.*—The vertical ascent of currents of air is one of the principal causes of the most important meteorological phenomena. Where a desert or a sandy surface devoid of vegetation is surrounded by a high mountain chain, the sea-wind may be observed driving a dense cloud over the desert, without any precipitation of vapor taking place before it reaches the crest of the mountains. This phenomenon was formerly very unsatisfactorily referred to an attraction supposed to be exercised by the mountain chain on the clouds. The true cause appears to lie in the ascent from the sandy plain of a column of warm air, which prevents the condensation of the vesicles of vapor. The more barren the surface, and the greater the degree of heat acquired by the sand, the higher will be the ascent of the clouds, and the less readily will the vapor be precipitated. Over the declivities of mountains these causes cease. The play of the vertical column of air is there weaker; the clouds sink, and their disintegration is effected by a cooler stratum of air. Thus deficiency of rain and absence of vegetation in the desert stand in a reciprocal action to one another. It does not rain because the barren and bare surface of sand becomes more strongly heated and radiates more heat; and the desert is not converted into a steppe or grassy plain because without water no organic development is possible.—HUMBOLDT *Views of Nature*, p. 266. (Bell, 1896.)

313. BASKET-MAKING OF PRIMITIVE PEOPLES—There are no savages on earth so rude that they have no form of basketry. The birds and beasts are basket-makers, and

some fishes construct for themselves little retreats where they may hide. Long before the fire-maker, the potter, or even the cook, came the mothers of the Fates, spinning threads, drawing them out, and cutting them off. Coarse basketry or matting is found charred in very ancient sepulchers.—MASON *Woman's Share in Primitive Culture,* ch. 3, p. 42. (A., 1894.)

314. BAS-RELIEFS OF NINEVEH—*Ancient Scenes Preserved—Gigantic Stature Given to Kings and Heroes.*—In the British Museum the alabaster bas-reliefs that adorned the palace courts of Nineveh give a wonderfully clear idea of what Assyrian life was like, how the king rode in his chariot, or let fly his arrows at the lion at bay, or walked with the state umbrella held over his head; how the soldiers swam the rivers on blown skins and the storming party scaled the fortress, while the archers shot down among them from the battlements, and the impaled captives hung in rows full in view outside the walls. But in such scenes proportion did not much matter if only the meaning were conveyed. It did not seem artistically absurd to the Assyrians to make archers so big that two fill a whole parapet; nor did the Egyptians feel the comic impression made on our modern minds by the gigantic figure of the king striding half across the battle-field and grasping a dozen pigmy barbarians at a grip, to slash their heads off with one sweep of his mighty falchion.—TYLOR *Anthropology,* ch. 12, p. 302. (A., 1899.)

315. BEAM OF LIGHT IN DARKNESS—*Gifted Men of Middle Ages—Rapid Spread of Investigation Once Started.*—The germ of those events which have imparted any strongly marked progressive movement to the human mind may be traced deeply rooted in the track of preceding ages. It does not lie in the destinies of mankind that all should equally experience mental obscuration. A principle of preservation fosters the eternal vital process of advancing reason. The Age of Columbus attained the object of its destination so rapidly because a track of fruitful germs had already been cast abroad by a number of highly gifted men, who formed, as it were, a lengthened beam of light amid the darkness of the Middle Ages. One single century—the thirteenth—shows us Roger Bacon, Nicolaus Scotus, Albertus Magnus, and Vincentius of Beauvais. The mental activity, once awakened, was soon followed by an extension of geographical knowledge. When Diego Ribero returned, in the year 1525, from the geographical and astronomical congress which had been held at the Puente de Caya, near Yelves, for the purpose of settling the contentions that had arisen regarding the boundaries of the two empires of the Portuguese and the Spaniards, the outlines of the new continent had been already laid down from Terra del Fuego to the coasts of Labrador. . . . The emulous enterprise of the Spaniards, English, and Portuguese, directed to one and the same object, was then so great that fifty years sufficed to determine the external configuration or the general direction of the coasts of the countries in the western hemisphere.—HUMBOLDT *Cosmos,* vol. ii, pt. ii, p. 229. (H., 1891.)

316. BEAUTIES OF NATURE NEGLECTED BY ROMANS—No description has been transmitted to us from antiquity of the eternal snow of the Alps reddened by the evening glow or the morning dawn, of the beauty of the blue ice of the glaciers, or of the sublimity of Swiss natural scenery, altho statesmen and generals, with men of letters in their retinue, continually passed through Helvetia on their road to Gaul. All these travelers think only of complaining of the wretchedness of the roads, and never appear to have paid any attention to the romantic beauty of the scenery through which they passed. . . . Silius Italicus, who died in the time of Trajan, when Switzerland was already considerably cultivated, describes the region of the Alps as a dreary and barren wilderness at the same time that he extols with admiration the rocky ravines of Italy and the woody shores of the Liris.—HUMBOLDT *Cosmos,* vol. ii, pt. i, p. 38. (H., 1897.)

317. BEAUTY AMID DESOLATION—*Fascination of Alaskan Glaciers—Continual Roar of Avalanches.*—The tide-water glaciers of Alaska are the ones that claim the greatest share of admiration from tourists on account of the wonderful coloring and marvelous beauty of their ice-cliffs and the picturesqueness of the floating islands of ice to which they give origin. The approach to a tide-water glacier is usually first made known by the fleet of bergs that dot the water and chill the atmosphere. These become more numerous as one proceeds, and many times completely cover the water before the ice-cliffs from which they came can be seen. Indeed, at times, the floating bergs form an impenetrable pack through which it is impossible for a vessel to advance. The vicinity of a glacier which terminates in the sea is frequently made manifest also by the roar of avalanches, as fresh masses of ice fall from its face and join the fleet of gleaming bergs crowding the adjacent waters. The noise of the falling fragments may be heard many miles, and sounds like distant thunder or the discharge of heavy guns.

When a large tide-water glacier is seen for the first time, the beholder is fascinated by its beauty, especially if it is illuminated by a brilliant sun, and learns a new lesson, for the reason that the scene is so different from the popular idea of the appearance of glaciers, derived principally from the

well-known ice streams of Switzerland.—RUSSELL *Glaciers of North America*, ch. 6, p. 77. (G. & Co., 1897.)

318. ——— ——— *Gorgeous Sunset among Desert Ranges of Utah.*—The unusually clear air of Utah, especially after the winter rains, renders distant mountains remarkably sharp and distinct, particularly when the sun is low in the sky and a strong side-light brings the sharp serrate crests into bold relief and reveals a richness of sculpturing that was before unseen. At such time the colors on the broad deserts, and amid the purple hills and mountains, are more wonderful than artists have ever painted, and exceed anything of the kind witnessed by the dweller of regions where the atmosphere is moist and the native tints of the rock concealed by vegetation. The hills of New England when arrayed in all the gorgeous panoply of autumnal foliage are not more striking than the desert ranges of Utah when ablaze with the reflected glories of the sunset sky. The rich, native colors of the naked rocks are then kindled into glowing fires, and each cañon and rocky gorge is filled with liquid purple, beside which even the imperial dyes would be dull and lusterless. At such times the glories of the hills are mirrored in the dense water of the lake; their duplicate forms appearing in sharp relief on the paler tints of the reflected sky. As the sun sinks behind the far-off mountains, range after range fades through innumerable shades of purple and violet until only their highest battlements catch the fading glory. The lingering twilight brings softer and more mysterious beauties. Ranges and peaks that were concealed by the glare of the noonday sun start into life. Forms that were before unnoticed people the distant plain like a shadowy encampment. At last each remote mountain crest appears as a delicate silhouette, in which all details are lost, drawn in the softest of violet tints on the fading yellow of the sky.—RUSSELL *Lakes of North America*, ch. 4, p. 79. (G. & Co., 1895.)

319. BEAUTY AND FERTILITY OF EARTH DUE TO DESPISED ORGANISMS—*Worms Antedate and Still Supplement the Plow.*—When we behold a wide, turf-covered expanse, we should remember that its smoothness, on which so much of its beauty depends, is mainly due to all the inequalities having been slowly leveled by worms. It is a marvelous reflection that the whole of the superficial mold over any such expanse has passed, and will again pass, every few years through the bodies of worms. The plow is one of the most ancient and most valuable of man's inventions; but long before he existed the land was in fact regularly plowed, and still continues to be thus plowed by earthworms. It may be doubted whether there are many other animals which have played so important a part in the history of the world as have these lowly organized creatures. Some other animals, however, still more lowly organized, namely, corals, have done far more conspicuous work in having constructed innumerable reefs and islands in the great oceans; but these are almost confined to the tropical zones.—DARWIN *Formation of Vegetable Mould*, ch. 7, p. 91. (Hum., 1887.)

320. BEAUTY AND HARMONY EXIST ONLY IN THE SOUL—*The World vs. Man's Interpretation of It.*—Out in the external world surrounding us there exists neither sound nor song, neither noise nor quiet, but only periodical or fitful vibrating motion, or rest.

The most glorious music, the most inspired speech is nothing there, absolutely nothing except a wild, meaningless surf of sound-waves, a purely mechanical, grossly material movement of bodies that produce sound, and of particles of air that conduct it. Not until it reaches the purely subjective sphere of the sensation of hearing does the new, beautiful, and significant world come into being; but it exists nowhere except within ourselves, and only for us. It has absolutely no existence elsewhere.—CZERNAK *Vorlesung über das Ohr und das Hören.* (Translated for *Scientific Side-Lights.*)

321. BEAUTY AND MAJESTY COMBINED IN PALM—*Aspiring Upward Reach of Its Leaves.*—The direction of the leaves, together with the lofty stem, gives to the palms their character of high majesty. It is a characteristic of the physiognomical beauty of the palm that its leaves are directed aspiringly upwards. . . . Nature seems to have accumulated all the beauties of form in the Jagua palm, which, intermingled with the Cucurito or Vadgihai, whose stem rises to a height of 80 or even more than 100 feet, crowns the granite rocks at the cataracts of Atures and Maypures, and which we also occasionally saw on the lonely banks of the Cassiquiare. Their smooth and slender stems rise to a height of from 64 to 75 feet, projecting like a colonnade above the dense mass of the surrounding foliage.—HUMBOLDT *Views of Nature*, p. 301. (Bell, 96.)

322. ——— ——— *Height of Its Pillar-like Stem.*—Palms [are] the loftiest and most stately of all vegetable forms. To these, above all other trees, the prize of beauty has always been awarded by every nation; and it was from the Asiatic palm-world, or the adjacent countries, that human civilization sent forth the first rays of its early dawn. Marked with rings, and not unfrequently armed with thorns, the tall and slender shaft of this graceful tree rears on high its crown of shining, fan-like, or pinnated leaves, which are often curled like those of some gramineæ. Smooth stems of

the palm, which I carefully measured, rose to a height of 190 feet. The palm diminishes in size and beauty as it recedes from the equatorial towards the temperate zones. —HUMBOLDT *Views of Nature*, p. 223. (Bell, 1896.)

323. BEAUTY AND SUBLIMITY INACCESSIBLE AND BARREN—*Antarctic Ice-capped Continent.*—From about latitude 70° to 79° S. he [Sir J. Ross] found comparatively open water, and sailed along near the coast of a great mass of land, on which, however, it was impossible to set foot. Its shores were everywhere covered with ice projecting into the sea. A thick mass of ice capped the whole region, and bare rock was only seen where precipices rose high above the water. Mile after mile this unbroken rampart, often rising to a height of from two to three hundred feet, presented a hopeless barrier to the explorers. It evidently indicates the margin of a large and mountainous mass of land, perhaps of an Antarctic continent. From the top of the ice-cliff the dazzling white surface sloped up towards a range "whose lofty peaks, perfectly covered with eternal snow, rose to elevations varying from seven to ten thousand feet above the level of the ocean. The glaciers that filled their intervening valleys, and which descended from near the mountain summits, projected in many places several miles into the sea, and terminated in lofty perpendicular cliffs. In a few places the rocks broke through their icy covering, by which alone we could be assured that land formed the nucleus of this, to appearance, enormous iceberg."—BONNEY *Ice-work Present and Past*, pt. i, ch. 2, p. 57. (A., 1896.)

324. BEAUTY AN END IN NATURE—*Elaborate and Multiplied Ornament—Human Impulses Not Out of Harmony with Divine Intelligence.*—It would be to doubt the evidence of our senses and of our reason, or else to assume hypotheses of which there is no proof whatever, if we were to doubt that mere ornament, mere variety, are as much an end and aim in the workshop of Nature as they are known to be in the workshop of the goldsmith and the jeweler. Why should they not? The love and desire of these is universal in the mind of man. It is seen not more distinctly in the highest forms of civilized art than in the habits of the rudest savage, who covers with elaborate carving the handle of his war-club, or the prow of his canoe. Is it likely that this universal aim and purpose of the mind of man should be wholly without relation to the aims and purposes of his Creator? He that formed the eye to see beauty, shall he not see it? He that gave the human hand its cunning to work for beauty, shall his hand never work for it? How, then, shall we account for all the beauty of the world—for the careful provision made for it where it is only the secondary object, not the first?—ARGYLL *Reign of Law*, ch. 14, p. 114. (Burt.)

325. ——— ——— *Gorgeous Coloring of Humming-birds.*—Those who, by special study, have laid their minds alongside the mind of Nature in any of her provinces have generally imparted to them a true sense, so far as it goes, in the interpretation of her mysteries. Let us, then, hear what Mr. Gould says on the beauty of the humming-birds: "The members of most of the genera have certain parts of their plumage fantastically decorated, and in many instances most resplendent in color. My own opinion is that this gorgeous coloring of the humming-birds has been given for the mere purpose of ornament, and for no other purpose of special adaptation in their mode of life; in other words, that ornament and beauty, merely as such, was the end proposed."—ARGYLL *Reign of Law*, ch. 5, p. 137. (Burt.)

326. ——— ——— *Ornament Sought amid Devices for Concealment.*—Even in those cases, for example, where concealment is the main object in view, ornament is never forgotten, but lies, as it were, underneath, carried into effect under the conditions and limitations imposed by the higher law and the more special purpose. Thus, the feathers of the ptarmigan, tho confined by the law of assimilative coloring to a mixture of black and white or gray, have those simple colors disposed in crescent bars and mottlings of beautiful form, even as the lichens which they imitate spread in radiating lines and semicircular ripples over the weather-beaten stones. It is the same with all other birds whose color is the color of their home. For the purpose of concealment, their coloring would be equally effective if it were laid on without order or regularity of form. But this is never done. The required tints are always disposed in patterns, each varying with the genus and the species; varying for the mere sake of variation, and for the beauty which belongs to ornament. And where this purpose is not under the restraint of any other purpose controlling it and keeping it down as it were within comparatively narrow limits, how gorgeous are the results attained! What shall we say of flowers—those banners of the vegetable world which march in such various and splendid triumph before the coming of its fruits? What shall we say of the humming-birds—whose feathers are made to return the light which falls upon them, as if rekindled from intenser fires, and colored with more than all the colors of all the gems?—ARGYLL *Reign of Law*, ch. 4, p. 114. (Burt.)

327. BEAUTY AN END IN THE DIVINE MIND—*Microscopic Perfection in Hidden Rocks.*—There is unity of character in every scale, plate, and fin [among the ichthyolites of the Old Red Sandstone]—

unity such as all men of taste have learned to admire in those three Grecian orders from which the ingenuity of Rome was content to borrow, when it professed to invent—in the masculine Doric, the chaste and graceful Ionic, the exquisitely elegant Corinthian; and yet the unassisted eye fails to discover the finer evidences of this unity: it would seem as if the adorable Architect had brought it out in secret with reference to the Divine idea alone. The artist who sculptured the cherry-stone consigned it to a cabinet, and placed a microscope beside it; the microscopic beauty of these ancient fish was consigned to the twilight depths of a primeval ocean. There is a feeling which at times grows upon the painter and the statuary, as if the perception and lóve of the beautiful had been sublimed into a kind of moral sense. Art comes to be pursued for its own sake; the exquisite conception in the mind, or the elegant and elaborate model, becomes all in all to the worker, and the dread of criticism or the appetite of praise almost nothing. And thus, through the influence of a power somewhat akin to conscience, but whose province is not the just and the good, but the fair, the refined, the exquisite, have works prosecuted in solitude, and never intended for the world, been found fraught with loveliness.—MILLER *Old Red Sandstone*, ch. 5, p. 88. (G. & L., 1851.)

328. ——— ——— *Tyrannous Demand for Perfection Urges Artist On—All Tends to an Ideal.*—Sir Thomas Lawrence, when finishing, with the most consummate care, a picture intended for a semibarbarous, foreign court, was asked why he took so much pains with a piece destined, perhaps, never to come under the eye of a connoisseur. "I cannot help it," he replied; "I do the best I can, unable, through a tyrant feeling that will not brook offense, to do anything less." It would be perhaps overbold to attribute any such overmastering feeling to the Creator; yet certain it is, that among his creatures well-nigh all approximations towards perfection, in the province in which it expatiates, owe their origin to it, and that Deity in all his works is his own rule.—MILLER *Old Red Sandstone*, ch. 5, p. 88. (G. & L., 1851.)

329. BEAUTY DEFIES DEFINITION—The concept of beauty is exceedingly difficult. The effort to construct the notion of beauty always terminates in a logical chaos that bewilders me.—FISCHER *Aesthetik*. (Translated for *Scientific Side-Lights.)*

330. BEAUTY EMBOWERED AMID INHOSPITABLE MOUNTAINS—*Transparency of Mountain Lake.*—This "gem of the Sierra" [Lake Tahoe] is situated at an elevation of 6,200 feet above the sea and is enclosed in all directions by rugged, forest-covered mountain slopes which rise from two to over four thousand feet above its surface. Its expanse is unbroken by islands, and has an area of between 192 to 195 square miles. Its diameter from north to south is 21.6 miles and from east to west 12 miles. On looking down on Lake Tahoe from the surrounding pine-covered heights, one beholds a vast plain of the most wonderful blue that can be imagined. Near shore, where the bottom is of white sand, the waters have an emerald tint, but are so clear that objects far beneath the surface may be readily distinguished. Farther lakeward, the tints change by insensible gradation until the water is a deep blue, unrivaled even by the color of the ocean in its deepest and most remote parts. On calm summer days the sky, with its drifting cloud banks and the rugged mountains with their bare and usually snow-covered summits, are mirrored in the placid waters with such wonderful distinctness and such accuracy of detail, that one is at a loss to tell where the real ends and the duplicate begins. While floating on the lake in a boat, the transparency of the water gives the sensation that one is suspended in mid-air, as every detail on the bottom, fathoms below, is clearly discernible.—RUSSELL *Lakes of North America*, ch. 4, p. 63. (G. & Co., 1895.)

331. BEAUTY ENHANCED BY MYSTERY—*Towers and Castles of Native Rock—Mode of Rock-formation Unknown—Explanation Carries the Difficulty a Step Further Back.*—Every island and rocky crag that rose in Lake Lahontan became a center of accumulation for tufa deposits and was transformed into strange and frequently fantastic shapes by the material precipitated upon it. Now that the waters of the ancient sea have disappeared, these structures stand in the desert valleys like the crumbling ruins of towers, castles, domes, and various other shapes, in keeping with the desolation surrounding them. The finest examples of these water-built structures, some of them a hundred feet or more in height, occur about the border of Pyramid and Winnemucca lakes, or rising from their bottoms and still wholly or in part submerged. The islands in Pyramid Lake are sheathed from base to summit with these deposits and their precipitous sides given a convex outline, owing especially to the vast deposits of dendritic tufa, which was precipitated most abundantly midway up the slopes. . . . When the tufa towers and castle-like piles are broken, the concentric layers of which they are composed are revealed and fill one with wonder at the vast amount of material they contain, as well as attract the eye on account of the delicacy and beauty of their structure. Nowhere else in this country, and, so far as reported, nowhere else in the world, are rocks formed of precipitates from lake waters so magnificently displayed as in the desert valleys of Nevada.

The fascination of the weird and frequently wonderfully impressive scenery of the region formerly submerged beneath the waters of Lake Lahontan, is enhanced, at least to the geologist, by the fact that there is yet an unsolved mystery connected with the tufa deposits that start out as strange, gigantic forms from the desert haze, as one slowly traverses those bitter, alkaline lands. —RUSSELL *Lakes of North America*, ch. 6, p. 111. (G. & Co., 1895.)

332. BEAUTY IN NATURE OBJECTIVE —*Utility Might Dispense with the Beautiful.*—Herculean efforts have been made by modern evolutionists to eliminate altogether the idea of beauty from nature, by theories of sexual selection and the like, and to persuade us that beauty is merely utility in disguise, and even then only an accidental coincidence between our perceptions and certain external things. But in no part of their argument have they more signally failed in accounting for the observed facts, and in no part have they more seriously outraged the common sense and natural taste of men. In point of fact, we have here one of those great correlations belonging to the unity of nature—that indissoluble connection which has been established between the senses and the esthetic sentiments of man and certain things in the external world. But there is more in beauty than this merely anthropological relation. Certain forms, for example, adopted in the skeletons of the lower animals are necessarily beautiful because of their geometrical proportions. Certain styles of coloring are necessarily beautiful because of harmonies and contrasts which depend on the essential properties of the waves of light. Beauty is thus in a great measure independent of the taste of the spectator. It is also independent of mere utility, since, even if we admit that all these combinations of forms, motions, and colors which we call beautiful are also useful, it is easy to perceive that the end could often be attained without the beauty.—DAWSON *Facts and Fancies in Modern Science*, lect. 5, p. 198. (A. B. P. S.)

333. BEAUTY, NATURAL, MOLDS NATION—*Scenery of Greece—Intimate Association of Land and Sea.*—We must not forget that Grecian scenery presents the peculiar charm of an intimate association of land and sea, of shores adorned with vegetation, or picturesquely girt round by rocks gleaming in the light of aerial tints, and of an ocean beautiful in the play of the ever-changing brightness of its deep-toned moving waves. Altho to other nations, sea and land, in the different pursuits of life to which they give rise, appeared as two separate spheres of nature, the Greeks—not only those who inhabited the islands, but also those occupying the southern portion of the continent—enjoyed, almost everywhere, the aspect of the richness and sublime grandeur imparted to the scenery by the contact and mutual influence of the two elements.—HUMBOLDT *Cosmos*, vol. ii, pt. i, p. 25. (H., 1897.)

334. BEAUTY NOT MATCHED BY INTELLECT—*Naturalist Tires of the Exquisite Humming-bird.*—The longer he [the naturalist] observes any one species or individual, the more does he find in it to reward his attention; this is not the case, however, with humming-birds, which possess the avian body, but do not rank mentally with birds. The pleasure one takes in their beauty soon evaporates, and is succeeded by no fresh interest, so monotonous and mechanical are all their actions; and we accordingly find that those who are most familiar with them from personal observation have very little to say about them. A score of humming-birds, of as many distinct species, are less to the student of habits than one little brown-plumaged bird haunting his garden or the rush-bed of a neighboring stream; and, doubtless, for a reason similar to that which makes a lovely human face uninformed by intellect seem less permanently attractive than many a homelier countenance.—HUDSON *Naturalist in La Plata*, ch. 16, p. 211. (C. & H., 1895.)

335. BEAUTY OF CREVASSES IN GLACIERS — *Color Rivals Blue of Ocean Depths.*—The walls of crevasses in névé regions are of the most exquisite turquoise blue, the color deepening below the surface until it seems almost black. The only color in nature that rivals the blue of glacial ice is seen when one looks down into the unfathomable sea. The sides of crevasses are frequently hung with icicles, forming rank on rank of glittering pendants, and fretted and embossed in the most beautiful manner with snow-wreaths, and partially roofed with curtain-like cornices of snow. These details are wrought in silvery white, or in innumerable shades of blue with suggestions of emerald tints. When the sunlight enters the great chasms, their walls seem incrusted with iridescent jewels. The still waters with which many of the gulfs are partially filled reflect every detail of their crystal walls and make their depth seem infinite. No dream of fairy caverns ever exceeded the beauty of these mysterious crypts of the vast cathedral-like amphitheaters of the silent mountains.—RUSSELL *Glaciers of North America*, int., p. 8. (G. & Co., 1897.)

336. BEAUTY OF NATURE SECONDARY IN GREEK POETRY—We find the most attractive scenes of nature introduced in the Homeric songs merely as secondary adjuncts. "The shepherd rejoices in the stillness of night, in the purity of the sky, and in the starry radiance of the vault of heaven; he hears from afar the rush of the mountain torrent, as it pursues its foaming course swollen with the trunks of oaks that have been borne along by its turbid waters"

[Iliad, viii, 555]. The sublime description of the sylvan loneliness of Parnassus, with its somber, thickly wooded and rocky valleys, contrasts with the joyous pictures of the many-fountained poplar groves in the Phæacian island of Scheria, and especially of the land of the Cyclops, "where meadows waving with luxuriant and succulent grass encircle the hills of unpruned vines" [Od., xix, 431]. Pindar, in a dithyrambus in praise of spring, recited at Athens, sings of "the earth covered with new-born flowers, when, in the Argive Nemæa, the first opening shoot of the palm announces the coming of balmy spring." Then he sings of Etna as "the pillar of heaven, the fosterer of enduring snow"; but he quickly turns away from these terrific forms of inanimate nature to celebrate Hiero of Syracuse, and the victorious combats of the Greeks with the mighty race of the Persians.—HUMBOLDT *Cosmos*, vol. ii, pt. i, p. 24. (H., 1897.)

337. BEAUTY OF ORCHIDS—*Innumerable Variety in South America.*—While these plants [of the cactus family] form green oases in the barren desert, the orchidaceæ shed beauty over the most desolate rocky clefts, and the seared and blackened stems of those tropical trees which have been discolored by the action of light. The *Vanilla* form is distinguished by its light-green succulent leaves, and by its variegated and singularly shaped blossoms. Some of the orchidaceous flowers resemble in shape winged insects, while others look like birds, attracted by the fragrance of the honey vessels. An entire life would not suffice to enable an artist, altho limiting himself to the specimens afforded by one circumscribed region, to depict the splendid orchidaceæ which embellish the deep alpine valleys of the Peruvian Andes.—HUMBOLDT *Views of Nature*, p. 220. (Bell, 1896.)

338. BEAUTY OF WILD PLANT FAILS UNDER CULTIVATION—*The Pampas Grass.*—On moist clayey ground flourishes the stately pampa grass, *Gynerium argenteum*, the spears of which often attain a height of eight or nine feet. I have ridden through many leagues of this grass with the feathery spikes high as my head, and often higher. . . . Every one is familiar with it in cultivation; but the garden plant has a sadly decaying, draggled look at all times, and to my mind is often positively ugly, with its dense withering mass of coarse leaves, drooping on the ground, and bundle of spikes, always of the same dead white or dirty cream color. Now color—the various ethereal tints that give a blush to its cloud-like purity—is one of the chief beauties of this grass on its native soil; and travelers who have galloped across the pampas at a season of the year when the spikes are dead, and white as paper or parchment, have certainly missed its greatest charm. The plant is social, and in some places where scarcely any other kind exists it covers large areas with a sea of fleecy white plumes; in late summer, and in autumn, the tints are seen, varying from the most delicate rose, tender and illusive as the blush on the white under-plumage of some gulls, to purple and violaceous. At no time does it look so perfect as in the evening, before and after sunset, when the softened light imparts a mistiness to the crowding plumes, and the traveler cannot help fancying that the tints, which then seem richest, are caught from the level rays of the sun, or reflected from the colored vapors of the afterglow.—HUDSON *Naturalist in La Plata*, ch. 1, p. 6. (C. & H., 1895.)

339. BEAUTY RESULTING FROM INTERFERENCE OF WAVES—*Richly Chased Pattern on Surface of Mercury.*—To the eye of a person conversant with these principles, nothing can be more interesting than the crossing of water ripples. Through their interference the water surface is sometimes shivered into the most beautiful mosaic, trembling rhythmically as if with a kind of visible music. When waves are skilfully generated in a dish of mercury, a strong light thrown upon the shining surface, and reflected on to a screen, reveals the motions of the liquid metal. The shape of the vessel determines the forms of the figures produced. In a circular dish, for example, a disturbance at the center propagates itself as a series of circular waves, which, after reflection, again meet at the center. If the point of disturbance be a little way removed from the center, the interference of the direct and reflected waves produces magnificent chasing. The light reflected from such a surface yields a pattern of extraordinary beauty. When the mercury is slightly struck by a needle-point in a direction concentric with the surface of the vessel, the lines of light run round in mazy coils, interlacing and unraveling themselves in a wonderful manner. When the vessel is square, a splendid checker-work is produced by the crossing of the direct and reflected waves. Thus, in the case of wave-motion, the most ordinary causes give rise to most exquisite effects. The words of your countryman, Emerson, are perfectly applicable here:

"Thou canst not wave thy staff in the air,
Or dip thy paddle in the lake,
But it carves the brow of beauty there,
And the ripples in rimes the oars forsake."

—TYNDALL *Lectures on Light*, lect. 2, p. 54. (A., 1898.)

340. BEAUTY REVEALED BY SUBDUED LIGHT—To one who only beholds the desert land bordering Great Salt Lake in the full glare of the unclouded summer sun, when the peculiar desert haze shrouds the landscape and the strange mirage distorts the outline of the hills, the scenery will no doubt be uninteresting and perhaps

ven repellent. But let him wait until the ool breath from the mountains steals out n the plain and the light becomes less intense, and a transformation will be witessed that will fill his heart with wonder. —RUSSELL *Lakes of North America,* ch. 4, ı. 79. (G. & Co., 1895.)

341. BEES MERCILESS UTILITARIANS—*Individual Sacrificed to Public Welfare.* —Bees are a peculiar people; they know ıo mercy, no gratitude, and grant no pensions. They maintain every one as long as s necessary for the general welfare, but .fter that they make away with him as ıuickly as possible.—GLOCK *Symbolik der Bienen.* (Translated for *Scientific Sidelights.)*

342. BEES VENTILATE THEIR HIVES —*Air-currents Driven by Fanning Wings— Natural Precursor of the Electric Fan.*— Very interesting [says Büchner], and closely onnected with this characteristic of cleaniness, is the conduct of the so-called venilating-bees, which have to take care that n summer or hot weather the air necessary or respiration of the bees in the interior ıf the hive is renewed, and the too high emperature cooled down. The latter preaution is necessary, not only on account ıf the bees working within the hive, to vhom, as already said, a temperature risen ıeyond a certain point would be intolerable, ıut also to guard against the melting or oftening of the wax. The bees charged vith the care of the ventilation divide hemselves into rows and stages in regular ırder through all parts of the hive, and by swift fanning of their wings send little currents of air in such fashion that a powerful tream or change of air passes through all ɔarts of the hive. Other bees stand at the nouth of the hive, which fan in the same vay and considerably accelerate the wind 'rom within. The current of air thus caused s so strong that little bits of paper hung n front of the mouth are rapidly moved. ınd that, according to F. Huber, a lighted natch is extinguished. The wind can be listinctly felt if the hand be held in front. —ROMANES *Animal Intelligence,* ch. 4, p. 191. (A., 1899.)

343. BEGINNING NECESSARILY SUPERNATURAL—If the universe had a beginning, its beginning, by the very conditions of the case, was supernatural: the laws of Nature cannot account for their own origin.—MILL *Positive Philosophy of Auguste Comte,* p. 15. (H. H. & Co., 1887.)

344. BEGINNING OF LIFE SOMEWHERE—*Earth Once Lifeless — Origin Requires Creative Power.*—These different sets of inhabitants who have possessed the earth at successive periods have each a character of their own. The transmutation theory insists that they owe their origin to gradual transformations, and are not, therefore, the result of distinct creative acts. All agree, however, that we arrive at a lower stratum where no trace of life is to be found. Place it where we will: suppose that we are mistaken in thinking that we have reached the beginning of life with the lowest Cambrian deposit; suppose that the first animals preceded this epoch, and that there was an earlier epoch, to be called the Laurentian system, besides many others older still; it is nevertheless true that geology brings us down to a level at which the character of the earth's crust made organic life impossible. At this point, wherever we place it, the origin of animals by development was impossible, because they had no ancestors. This is the true starting-point, and until we have some facts to prove that the power, whatever it was, which originated the first animals has ceased to act, I see no reason for referring the origin of life to any other cause.—AGASSIZ *Journey in Brazil,* ch. 1, p. 43. (H. M. & Co., 1896.)

345. BEGINNING OF LIFE-WORK IN MIDDLE AGE—*Herschel's Great Work Done after His Fortieth Year—Prodigious Labors —Discovery of Uranus.*—He [Herschel] had entered upon his forty-second year when he sent his first paper to the *Philosophical Transactions;* yet during the ensuing thirty-nine years his contributions—many of them elaborate treatises—numbered sixty-nine, forming a series of extraordinary importance to the history of astronomy. As a mere explorer of the heavens his labors were prodigious. He discovered 2,500 nebulæ, 806 double stars, passed the whole firmament in review four several times, counted the stars in 3,400 "gage fields," and executed a photometric classification of the principal stars, founded on an elaborate (and the first systematically conducted) investigation of their relative brightness. He was as careful and patient as he was rapid; spared no time and omitted no precaution to secure accuracy in his observations; yet in one night he would examine, singly and attentively, up to 400 separate objects.

The discovery of Uranus was a mere incident of the scheme he had marked out for himself—a fruit, gathered as it were by the way. It formed, nevertheless, the turning-point in his career. From a star-gazing musician he was at once transformed into an eminent astronomer: he was relieved from the drudgery of a toilsome profession and installed as Royal Astronomer.— CLERKE *History of Astronomy,* ch. 1, p. 15. (Bl., 1893.)

346. BEGINNING, THE, TO BE INTERPRETED BY THE END—*Man the End in Evolution.*—If evolution can be proved to include man, the whole course of evolution and the whole scheme of Nature from that moment assume a new significance. The beginning must then be interpreted from the end, not the end from the beginning. An engineering workshop is unintelligible until

we reach the room where the completed engine stands. Everything culminates in that final product, is contained in it, is explained by it. The evolution of man is also the complement and corrective of all other forms of evolution. From this height only is there a full view, a true perspective, a consistent world.—DRUMMOND *Ascent of Man*, p. 9. (J. P., 1900.)

347. BEGINNINGS OF ASTRONOMY—*Chaldeans the First Astronomers—Careful Observations of the Greeks.*—The Greek astronomers of a later age not only rejected the vague speculations of their ancestors, but proved themselves the most careful observers of their time, and first made astronomy worthy the name of a science. From this Greek astronomy the astronomy of our own time may be considered as coming by direct descent. Still, were it not for the absence of historic records, we could probably trace back both their theories and their system of observation to the plains of Chaldea. The zodiac was mapped out and the constellations named many centuries before they commenced their observations, and these works marked quite an advanced stage of development.—NEWCOMB *Popular Astronomy*, pt. i. int., p. 5. (H., 1899.)

348. ——— ——— *Hipparchus Anticipated Ptolemy—Cycles and Epicycles.*—If we confine ourselves to men whose names and whose labors have come down to us, we must concede to Hipparchus the honor of being the father of astronomy. Not only do his observations of the heavenly bodies appear to have been far more accurate than those of any of his predecessors, but he also determined the laws of the apparent motions of the planets, and prepared tables by which these motions could be calculated. Probably he was the first propounder of the theory of epicyclic motions of the planets, commonly called after the name of his successor, Ptolemy, who lived three centuries later.—NEWCOMB *Popular Astronomy*, pt. i, int., p. 5. (H., 1899.)

349. BEGINNINGS OF SCIENCE—*Superstition Mingled with Real Knowledge.*— . . . A peculiar characteristic of the Tuscans was their inclination for cultivating an intimate connection with certain natural phenomena. Divination, which was the occupation of their equestrian hierarchical caste, gave occasion for a daily observation of the meteorological processes of the atmosphere. The Fulguratores, observers of lightning, occupied themselves in investigating the direction of the lightning, with "drawing it down" and "turning it aside." They carefully distinguished between flashes of lightning from the higher regions of the clouds, and those which Saturn, an earth-god, caused to ascend from below, and which were called Saturnine terrestrial lightning, a distinction which modern physicists have thought worthy of especial attention. Thus were established regular official notices of the occurrence of storms. The *Aquælicium*, the art of discovering springs of waters, which was much practised by the Etruscans, and the drawing forth of water by their *Aquilcges*, indicate a careful investigation of the natural stratification of rocks and of the inequalities of the ground. Diodorus, on this account, extols the Etruscans as industrious inquirers of Nature.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 139. (H., 1897.)

350. BEGINNINGS OF SCULPTURE—*Indian Pipes Molded to Figures of Men and Animals.*—Among the most characteristic specimens of ancient American pottery are the pipes. Some of these are simple bowls, not unlike a common every-day pipe, from which they differ in having generally no stem, the mouth having apparently been applied direct to the bowl. Many are highly ornamented, others are spirited representations of monsters or of animals, such as the beaver, otter, wildcat, elk, bear, wolf, panther, raccoon, opossum, squirrel, manatee, eagle, hawk, heron, owl, buzzard, raven, swallow, parrakeet, duck, grouse, and many others. The most interesting of these, perhaps, is the manatee or lamantin, of which seven representations have been found in the mounds of Ohio. These are no mere rude sculptures, about which there might easily be a mistake, but we are assured that "the truncated head, thick semicircular snout, peculiar nostrils, tumid, furrowed upper lip, singular feet or fins, and remarkable mustaches, are all distinctly marked, and render the recognition of the animal complete." This curious animal is not at present found nearer than the shores of Florida, a thousand miles away.—AVEBURY *Prehistoric Times*, ch. 8, p. 242. (A., 1900.)

351. BEGINNINGS RUDE AND POOR—*Ancestors of Steam-plow, Harvester, and Thresher.*—The ancestor of the steam-plow is the digging-stick of savagery, a branch of a tree sharpened at the end by fire; the progenitors of the steam-harvester and thresher were the stone sickle, the roasting-tray, or, later on, the tribulum.—MASON *Birth of Invention, Address at Centenary of Amer. Patent System, Washington, D. C., 1891.* Proceedings of the Congress, p. 407.

352. BELIEF BEFORE DISCOVERY—*Ross Confident of the Existence of Deep-sea Life.*—In the narrative of the voyage of the "Erebus" and "Terror," published in 1847, Sir James Ross [writes]: "It is well known that marine animals are more susceptible of change of temperature than land animals; indeed they may be isothermally arranged with great accuracy. It will, however, be difficult to get naturalists to believe that these fragile creatures could possibly exist at the depth of nearly 2,000 fathoms below the surface; yet as we know they can bear the pressure of 1,000 fathoms, why

may they not of two? We also know that several of the same species of creatures inhabit the Arctic that we have fished up from great depths in the Antarctic seas. The only way they could get from one pole to the other must have been through the tropics; but the temperature of the sea in those regions is such that they could not exist in it, unless at a depth of nearly 2,000 fathoms. At that depth they might pass from the Arctic to the Antarctic Ocean without a variation of five degrees of temperature; whilst any land animal, at the most favorable season, must experience a difference of fifty degrees, and, if in the winter, no less than 150 degrees of Fahrenheit's thermometer—a sufficient reason why there are neither quadrupeds, nor birds, nor land insects common to both regions."—HICKSON *Fauna of the Deep Sea*, ch. 1, p. 3. (A., 1894.)

353. BELIEF IN A FUTURE LIFE—*Ancient British Islanders.*—The care with which the dead were interred, and the custom [prevalent, but not universal] of burying implements with them, may fairly be regarded as indicating the existence of a belief in the immortality of the soul, and in a material existence after death.

The objects buried with the dead are sometimes numerous, and always interesting. In a large tumulus near Everley, a deposit of burnt bones was "surrounded by a circular wreath of horns of the red-deer"; whilst at a higher level, tho three feet from the summit, was the skeleton of a small dog, the "attendant in the chase, and perhaps the victim in death," of the hunter, whose exquisitely chipped arrow-heads, five in number, were deposited with his ashes.—AVEBURY *Prehistoric Times*, ch. 5, p. 133. (A., 1900.)

354. ——— ——— *Favorite Objects Buried with the Dead—American Indians.*—The remark made by Schoolcraft as regards the American Indians is applicable to many savage tribes. "Nothing that the dead possessed was deemed too valuable to be interred with the body. The most costly dress, arms, ornaments, and implements, are deposited in the grave," which is "placed in the choicest scenic situations—on some crowning hill or gentle eminence in a secluded valley." And the North-American Indians are said, even until within the last few years, to have long cherished a friendly feeling for the French, because, in the time of their supremacy, they had at least this one great merit, that they never disturbed the resting-places of the dead.—AVEBURY *Prehistoric Times*, ch. 5, p. 123. (A., 1900.)

355. BELIEF IN ILLUSIONS OF OTHERS—*Every Man Attributes the Failing to All the Rest.*—Most men are sometimes liable to illusion. Hardly anybody is always consistently sober and rational in his perceptions and beliefs. A momentary fatigue of the nerves, a little mental excitement, a relaxation of the effort of attention by which we continually take our bearings with respect to the real world about us, will produce just the same kind of confusion of reality and phantasm which we observe in the insane. To give but an example: the play of fancy which leads to a detection of animal and other forms in clouds is known to be an occupation of the insane, and is rightly made use of by Shakespeare as a mark of incipient mental aberration in Hamlet; and yet this very same occupation is quite natural to children, and to imaginative adults when they choose to throw the reins on the neck of their fantasy. Our luminous circle of rational perception is surrounded by a misty penumbra of illusion. Common sense itself may be said to admit this, since the greatest stickler for the enlightenment of our age will be found in practise to accuse most of his acquaintance at some time or another of falling into illusion.—SULLY *Illusions*, ch. 1, p. 3. (A., 1897.)

356. BELIEF IN THE UNKNOWABLE A NECESSITY—*Human Personality Inexplicable—Agnosticism Accepts the Mystery.*—Let us ask him [the agnostic] if he can subscribe to the simple creed expressed in the words "I am, I feel, I think." Should he deny these propositions, then there is no basis left on which to argue. Should he admit this much of belief, he has abandoned somewhat of his agnostic position; for it would be easy to show that in even uttering the pronoun "I" he has committed himself to the belief in the unknowable. What is the ego which he admits? Is it the material organism or any one of its organs or parts? or is it something distinct, of which the organism is merely the garment, or outward manifestation? or is the organism itself anything more than a bundle of appearances partially known and scarcely understood by that which calls itself "I"? Who knows? And if our own personality is thus inscrutable, if we can conceive of it neither as identical with the whole or any part of the organism, nor as existing independently of the organism, we should begin our agnosticism here, and decline to utter the pronoun "I" as implying what we cannot know.—DAWSON *Facts and Fancies in Modern Science*, lect. 1, p. 22. (A. B. P. S.)

357. BELIEF NOT FORCED BY WILL—*Created by Action According to Facts: "If Any Man Will Do His Will" (John vii, 17).*—If belief consists in an emotional reaction of the entire man on an object, how can we believe at will? We cannot control our emotions. Truly enough, a man cannot believe at will abruptly. Nature sometimes, and indeed not very infrequently, produces instantaneous conversions for us. She suddenly puts us in an active connec-

tion with objects of which she had till then left us cold. "I realize for the first time," we then say, "what that means!" This happens often with moral propositions. We have often heard them; but now they shoot into our lives; they move us; we feel their living force. Such instantaneous beliefs are truly enough not to be achieved by will. But gradually our will can lead us to the same results by a very simple method: we need only in cold blood act as if the thing in question were real, and keep acting as if it were real, and it will infallibly end by growing into such a connection with our life that it will become real. It will become so knit with habit and emotion that our interests in it will be those which characterize belief. Those to whom "God" and "Duty" are now mere names can make them much more than that if they make a little sacrifice to them every day.—JAMES *Psychology*, vol. ii, ch. 21, p. 321. (H. H. & Co., 1899.)

358. BELIEF THAT NO SUNLIGHT PENETRATES TO DEPTHS OF SEA—Until quite recently, every one agreed that no rays of sunlight could possibly penetrate the sea to a greater depth than a few hundred fathoms. Moseley says that "probably all is dark below 200 fathoms excepting in so far as light is given out by phosphorescent animals," and Wyville Thomson speaks of the "utter darkness of the deep-sea bottom."—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 22. (A., 1894.)

359. BENEFITS CONFERRED BY UNSEEN ORGANISMS—*Their Action Essential to Best Quality of Butter—Bacteria Have Economic Value.*—Cream in ordinary dairies and creameries invariably contains some bacteria, a large number of which are in no sense injurious. Indeed, it is to these bacteria that the ripening and flavoring processes are due. They are perfectly consistent with the production of the best quality of butter. The aroma of butter, as we know, controls in a large measure its price in the market. This aroma is due to the decomposing effect upon the constituents of the butter of the bacteria contained in the cream. In the months of May and June the variety and number of these types of bacteria are decidedly greater than in the winter months, and this explains in part the better quality of the butter at these seasons.—NEWMAN *Bacteria*, ch. 6, p. 215. (G. P. P., 1899.)

360. BENEFITS OF FIRE—*Range of Habitation Widened—Forests Subdued—Canoes Invented—Eskimos and Cave-men.*—Incalculable were the gains that began to flow in upon the first fire-maker, his victory won, its spoils assured. Beneath his tread the globe expanded itself with invitation, for now no longer chained by the sunbeam, he added all the frozen North to his hunting-ground. The Eskimos, according to Professor Dawkins, are the lineal descendants of the cave-men. They are the only American aborigines who have invented a lamp; that simple device has enabled them to conquer and hold an outpost twenty degrees nearer the pole than any other human settlement. Whether the first explorers had caves to fall back upon or not, fire was indispensable to them. A burning brand cleared their paths through forests otherwise impenetrable. When they singled out a tree for their rude carpentry, it was no longer cut down by flints so soon dulled and broken in the process. Fire cunningly applied, to be as cunningly quenched with wet mud, had a sharper and quicker tooth than stone. The tree felled, its trunk was softened and shaped, again by fire, into a canoe for voyages too daring for any raft.—ILES *Flame, Electricity, and the Camera*, ch. 3, p. 24. (D. & McC., 1900.)

361. BENEFITS POSSIBLE IN UNKNOWN FUTURE—*Studies Not To Be Limited to Manifest Demand.*—Let me, firstly, note that those who object to study any subject which they themselves deem unconnected with their own special life and avocation, commit the illogical, and I must say illiberal, mistake of seeking to limit their intellectual progress from a very unreasonable motive and cause. Because such persons consider any particular study of no use, or, what is still more absurd, because they think that it cannot be of any future service to them, the study is rejected. But one is naturally tempted to ask of such persons how, without pretending to possess a special gift of prophecy, they can attain to any knowledge of what will or what will not be of service to them in the future? Who can, in the first place, and as a matter of common-sense detail, reasonably assert that they will never be in any position, or placed in any circumstances, in which a knowledge of the despised branch will not come handy, and even be of valuable nature to them? Human policy in this respect, and especially that which would take upon itself the office of educational censor, and of deciding according to its narrow lights what should or should not be studied in view of the unknown future, is of a very short-sighted kind. The study we prosecute from a liking for it, and in our leisure time, may in the days of the future become the prop and mainstay of our physical and intellectual life, and may unfold sources of pleasure and gratification to us undreamt of until the occasion calls them forth.—ANDREW WILSON *Science-Culture for the Masses*, p. 26. (Hum., 1888.)

362. BENEFITS, RECIPROCAL, OF NATIONS IN SCIENCE—*The Royal Institution of Great Britain Founded by an American—The Smithsonian, by an Englishman.*—At the time of the American Revolution there resided in the town of Rumford, N. H., one Benjamin Thompson, who occupied him-

self in teaching a school. He embraced, as we Americans would say, the wrong side of the question on that occasion—he sided with the king's government. He went to England, became a man of mark, and was knighted. Then he went on the Continent, again distinguished himself by his scientific attainments, again was titled, and this time, in memory of his American home, was called Count Rumford. On his return to London, Count Rumford founded the Royal Institution, and thus to a native American the world owes that establishment which has been glorified by Davy, and Young, and Faraday. Had it not been for Rumford, Davy might have spent his life in filling gas-bags for Dr. Beddoes's patients, and Faraday might have been a bookbinder.

But if Benjamin Thompson, an American, founded the Royal Institution, James Smithson, an Englishman, shortly afterwards founded that noble institution in Washington which bears his name, and which, under the enlightened care of Prof. Henry, has so greatly ministered to the advancement and diffusion of science.—TYNDALL *Lectures on Light*, app. (Draper's Address), p. 235. (A., 1898.)

363. BIBLE THE ONLY STANDARD OF EARLY CHRISTIANS—*Science Measured by Scripture.*—The sufferings of the early Christians, and the extraordinary exaltation of mind which enabled them to triumph over the diabolical tortures to which they were subjected, must have left traces not easily effaced. They scorned the earth, in view of that "building of God, that house not made with hands, eternal in the heavens." The Scriptures which ministered to their spiritual needs were also the measure of their science. When, for example, the celebrated question of Antipodes came to be discussed, the Bible was with many the ultimate court of appeal. Augustine, who flourished A. D. 400, would not deny the rotundity of the earth: but he would deny the possible existence of inhabitants at the other side, "because no such race is recorded in Scripture among the descendants of Adam." Archbishop Boniface was shocked at the assumption of a "world of human beings out of the reach of the means of salvation." Thus reined in, science was not likely to make much progress.—TYNDALL *Fragments of Science*, vol. ii, ch. 9, p. 146. (A., 1897.)

364. BIGOTRY AND SCIENCE—*Descartes Assailed Alike by Catholics and by Protestants.*—Descartes lived and died a good Catholic, and prided himself upon having demonstrated the existence of God and of the soul of man. As a reward for his exertions, his old friends the Jesuits put his works upon the "Index," and called him an atheist, while the Protestant divines of Holland declared him to be both a Jesuit and an atheist. His books narrowly escaped being burned by the hangman; the fate of Vanini was dangled before his eyes; and the misfortunes of Galileo so alarmed him that he well-nigh renounced the pursuits by which the world has so greatly benefited, and was driven into subterfuges and evasions which were not worthy of him.—HUXLEY *Lay Sermons*, serm. 14, p. 342. (G. P. P., 1899.)

365. BINDING A SUBSTITUTE FOR NAILS AND CEMENT—*The Sennit of Oceanica.*—But the savage man's unfailing friend in holding together the parts of his tools is a seizing of some sort. It is so easy, so effective, so readily repaired, and it makes the handle stronger instead of weaker. Hence the Polynesian gentleman, when he goes out to visit or sits in the shade of his own vine and fig-tree, takes along a good quantity of coco-fiber and braids it into sennit. If the reader never saw a roll of sennit, it will pay him to visit the nearest ethnological museum for this sole purpose. The uniformity of the strands, the evenness of the braid, the incomparable winding on the roll or spool, as one might call it, constitute one of the fine arts of Oceanica. But prettier still are the regular, geometrical wrappings of this sennit when it is designed to hold an adz blade and handle in close union. While speaking of this combining substance, it may as well be said that in the building of houses the framework is held together entirely by the braided sennit. The strakes of a boat are united by its means. In short, whatsoever is wrapped for amusement or seriously, and whatsoever is nailed or screwed or pegged or glued in other lands, is in this region united by means of this textile.—MASON *Origins of Invention*, ch. 2, p. 41. (S., 1899.)

366. BIOLOGY, PROBLEMS OF, DEFY MECHANICAL EXPLANATION—I think that the more thoroughly and conscientiously we endeavor to study biological problems, the more we are convinced that even those processes which we have already regarded as explicable by chemical and physical laws are in reality infinitely more complex, and at present defy any attempt at a mechanical explanation.

Thus we have been satisfied to account for the absorption of food from the alimentary canal by the laws of diffusion and osmosis. But we now know that, as regards osmosis, the wall of the intestine does not behave like a dead membrane. We know that the intestinal wall is covered with epithelium, and that every epithelial cell is in itself an organism, a living being with the most complex functions. We know that it takes up food by the active contraction of its protoplasm in the same way as observed in independent naked animal cells.—BUNGE *Text-book of Physiological and Pathological Chemistry*, p. 3. [K. P. & Co.] (Translated for *Scientific Side-Lights.*)

367. BIRD ATTACKED FOR UNUSUAL COLOR—*A Stranger to Its Kind.*—Another instance of misdirected anger in nature, not quite so familiar as that of the bull and red rag, is used as an illustration by one of the prophets: "My heritage is unto me as a speckled bird; the birds round about are against it" [Jer. xii, 9]. I have frequently seen the birds of a thicket gather round some singularly marked accidental visitor, and finally drive him with great anger from the neighborhood. Possibly association comes in a little here, since any bird, even a small one, strikingly colored or marked, might be looked on as a bird of prey.—HUDSON *Naturalist in La Plata,* ch. 12, p. 167. (C. & H., 1895.)

368. BIRDS IN SUDDEN MULTITUDES—*How Explained—Unseen Hosts Ever Passing.*—On the pampas, whenever grasshoppers, mice, frogs, or crickets become excessively abundant we confidently look for the appearance of multitudes of the birds that prey on them. . . . It is plain that these birds have been drawn from over an immense area to one spot; and the question is how have they been drawn? Many large birds possessing great powers of flight are, when not occupied with the business of propagation, incessantly wandering from place to place in search of food. They are not, as a rule, regular migrants, for their wanderings begin and end irrespective of seasons, and where they find abundance they remain the whole year. They fly at a very great height, and traverse immense distances. When the favorite food of any one of these species is plentiful in any particular region all the individuals that discover it remain, and attract to them all of their kind passing overhead. This happens on the pampas with the stork, the short-eared owl, the hooded gull, and the dominican or black-backed gull—the leading species among the feathered nomads: a few first appear like harbingers; these are presently joined by newcomers in considerable numbers, and before long they are in myriads.—HUDSON *Naturalist in La Plata,* ch. 3, p. 64. (C. & H., 1895.)

369. BIRDS KILLED BY SPIDER—*The Gigantic Spider (Mygale) of Brazil—Confirmation of Early Narratives—Lower Life Preying on Higher.*—At Cametá I chanced to verify a fact relating to the habits of a large hairy spider of the genus *Mygale* in a manner worth recording. The species was *M. avicularia,* or one very closely allied to it; the individual was nearly two inches in length of body, but the legs expanded seven inches, and the entire body and legs were covered with coarse gray and reddish hairs. I was attracted by a movement of the monster on a tree-trunk; it was close beneath a deep crevice in the tree; across which was stretched a dense white web. The lower part of the web was broken, and two small birds, finches, were entangled in the pieces; they were about the size of the English siskin, and I judged the two to be male and female. One of them was quite dead; the other lay under the body of the spider not quite dead, and was smeared with the filthy liquor or saliva exuded by the monster. I drove away the spider and took the birds, but the second one soon died. The fact of species of *Mygale* sallying forth at night, mounting trees and sucking the eggs and young of humming-birds, has been recorded long ago by Madame Merian and Palisot de Beauvois; but, in the absence of any confirmation, it has come to be discredited. From the way the fact has been related it would appear that it had been merely derived from the report of natives, and had not been witnessed by the narrators. Count Langsdorff, in his "Expedition into the Interior of Brazil," states that he totally disbelieved the story. I found the circumstances to be quite a novelty to the residents hereabout. The mygales are quite common insects; some species make their cells under stones, others form artistic tunnels in the earth, and some build their dens in the thatch of houses. The natives call them *Aranhas caranguejeiras,* or crab-spiders. The hairs with which they are clothed come off when touched, and cause a peculiar and almost maddening irritation. The first specimen that I killed and prepared was handled incautiously, and I suffered terribly for three days afterward. I think this is not owing to any poisonous quality residing in the hairs, but to their being short and hard, and thus getting into the fine creases of the skin. Some mygales are of immense size. One day I saw the children belonging to an Indian family, who collected for me, with one of these monsters secured by a cord round its waist, by which they were leading it about the house as they would a dog.—BATES *Naturalist on the River Amazon,* ch. 4, p. 655. (Hum., 1880.)

370. BIRDS LOST IN WASTE OF AIR—*Fatal Fascination of Lighthouse.*—It is when fogs and storms obscure the view that birds lose their way. Then they fly much lower, perhaps seeking some landmark, and, should a lighthouse lie in their path, they are often attracted to it in countless numbers. Thousands of birds perish annually by striking these lights during stormy fall weather. In the spring the weather is more settled and fewer birds are killed.—CHAPMAN *Bird-Life,* ch. 4, p. 56. (A., 1900.)

371. BIRDS, MIGRATION OF—*An Almost Universal Law—Mystery in Familiar Things.*—The least observant person who walks even a short distance beyond the range of bricks and mortar cannot fail to notice that in early spring a strange uneasy movement seems to pervade every living thing. . . . But what betokens the arrival of spring even more than the crawling

of snails or the flutter of insects is the arrival of the migratory birds. That they are migratory is to most of us a matter of such familiar knowledge that we no more think of questioning it than we conceive it necessary to doubt the rotundity of the earth or the waning of the moon. We know that certain feathered friends are here during the summer, and it is equally certain that they are absent a few months later, only to appear with the first flowers and the pioneer bees. . . . All summer these little feathered folk revel in the joy of existence. The pair build their nest, rear their young, and disappear, until the observer who was intent six months before in watching their arrival may find a sadder but not less intellectual amusement in noting how one by one they vanish from the woods, the commons, the fields, the gardens, and the riversides, where they had to all appearance established themselves for good.—BROWN *Nature-Studies*, p. 11. (Hum., 1888.)

372. BIRDS' WINGS SELF-ACTING VALVES—*Adjustment to Upward and Downward Strokes.*—But there is another difficulty to be overcome [in flight]—a difficulty opposed by natural laws, and which can only be met by another adjustment, if possible more ingenious and beautiful than the rest. It is obvious that if a bird is to support itself by the downward blow of its wings upon the air, it must at the end of each downward stroke lift the wing upwards again, so as to be ready for the next. But each upward stroke is in danger of neutralizing the effect of the downward stroke. It must be made with equal velocity, and if it required equal force it must produce equal resistance—an equal rebound from the elasticity of the air. If this difficulty were not evaded somehow, flight would be impossible. But it is evaded by two mechanical contrivances, which, as it were, triumph over the laws of aerial resistance by conforming to them. One of these contrivances is, that the upper surface of the wing is made convex, whilst the under surface is concave. The enormous difference which this makes in atmospheric resistance is familiarly known to us by the difference between the effect of the wind on an umbrella which is exposed to it on the under or the upper side. The air which is struck by a concave or hollow surface is gathered up, and prevented from escaping: whereas the air struck by a convex or bulging surface escapes readily on all sides, and comparatively little pressure or resistance is produced. And so, from the convexity of the upper surface of a bird's wing, the upward stroke may be made with comparatively trifling injury to the force gained in the downward blow.

But this is only half of the provision made against a consequence which would be so fatal to the end in view. The other half consists in this—that the feathers of a bird's wing are made to underlap each other, so that in the downward stroke the pressure of the air closes them upwards against each other, and converts the whole series of them into one connected membrane, through which there is no escape; whilst in the upward stroke the same pressure has precisely the reverse effect—it opens the feathers, separates them from each other, and converts each pair of feathers into a self-acting valve, through which the air rushes at every point.—ARGYLL *Reign of Law*, ch. 3, p. 81. (Burt.)

373. BIRTH OF GEOLOGY—*Early Study of the Neptunian or Stratified Rocks.*—In the latter part of the eighteenth century, extensive mining operations in Saxony gave rise to an elaborate investigation of the soil for practical purposes. It was found that the rocks consisted of a succession of materials following each other in regular sequence, some of which were utterly worthless for industrial purposes, while others were exceedingly valuable. . . . But while the workmen wrought at these successive layers of rock to see what they would yield for practical purposes, a man [Werner] was watching their operations who considered the crust of the earth from quite another point of view. . . . From the general character of these rocks, as well as the number of marine shells contained in them, he convinced himself that the whole series, including the coal, . . . the red sandstone, and the *Muschel-Kalk*, had been deposited under the agency of water, and were the work of the ocean.—AGASSIZ *Geological Sketches*, ser. i, ch. 4, p. 113. (H. M. & Co., 1896.)

374. —— —— *Hutton Studies the Plutonic or Igneous Rocks.*—But, in the meantime [compare 373], James Hutton, a Scotch geologist, was looking at phenomena of a like character from a very different point of view. In the neighborhood of Edinburgh, where he lived, was an extensive region of trap-rock—that is, of igneous rock, which had forced itself through the stratified deposits, sometimes spreading in a continuous sheet over large tracts, or splitting them open and filling all the interstices and cracks so formed. Thus he saw igneous rocks not only covering or underlying stratified deposits, but penetrating deep into their structure, forming dikes at right angles with them, and presenting, in short, all the phenomena belonging to volcanic rocks in contact with stratified materials. He again pushed his theory too far, and, inferring from the phenomena immediately about him that heat had been the chief agent in the formation of the earth's crust, he was inclined to believe that the stratified materials also were in part at least due to this cause.—AGASSIZ *Geological Sketches*, ser. i, ch. 4, p. 115. (H. M. & Co., 1896.)

375. BLACKNESS OF ATLANTIC DEPTHS—*Reflection Necessary To Give Color—Solid Particles in Suspension Give the Green Hue to Shoal Water.*—If, then, we render water sufficiently deep to quench all the light, and if from the interior of the water no light reaches the eye, we have the condition necessary to produce blackness. Looked properly down upon there are portions of the Atlantic Ocean to which one would hardly ascribe a trace of color: at the most a tint of dark indigo reaches the eye. The water, in fact, is practically black, and this is an indication both of its depth and purity. But the case is entirely changed when the ocean contains solid particles in a state of mechanical suspension, capable of sending light back to the eye. Throw, for example, a white pebble into the blackest Atlantic water; as it sinks it becomes greener and greener, and, before it disappears, it reaches a vivid blue green. Break such a pebble into fragments, these will behave like the unbroken mass; grind the pebble to powder, every particle will yield its modicum of green; and if the particles be so fine as to remain suspended in the water, the scattered light will be a uniform green. Hence the greenness of shoal water. You go to bed with the black water of the Atlantic around you. You rise in the morning, find it a vivid green, and correctly infer that you are crossing the bank of Newfoundland. Such water is found charged with fine matter in a state of mechanical suspension. The light from the bottom may sometimes come into play, but it is not necessary. The subaqueous foam generated by the screw or paddle-wheels of a steamer also sends forth a vivid green. The foam here furnishes a reflecting surface, the water between the eye and it the absorbing medium. —TYNDALL *Lectures on Light*, lect. 1, p. 35. (A., 1898.)

376. BLINDNESS OF INSTINCT—*Squirrel Burying Nut.*—[The following] instance is given by Dr. H. D. Schmidt, of New Orleans, in the "Transactions of American Neurological Association," vol. i, p. 129 (1875): "I may cite the example of a young squirrel which I had tamed, a number of years ago, when serving in the army, and when I had sufficient leisure and opportunity to study the habits of animals. In the autumn, before the winter sets in, adult squirrels bury as many nuts as they can collect, separately, in the ground. Holding the nut firmly between their teeth, they first scratch a hole in the ground, and, after pointing their ears in all directions to convince themselves that no enemy is near, they ram—the head, with the nut still between the front teeth, serving as a sledge-hammer—the nut into the ground, and then fill up the hole by means of their paws. The whole process is executed with great rapidity, and, as it appeared to me, always with exactly the same movements; in fact, it is done so well that I could never discover the traces of the burial-ground. Now, as regards the young squirrel, which, of course, never had been present at the burial of a nut, I observed that, after having eaten a number of hickory-nuts to appease its appetite, it would take one between its teeth, then sit upright and listen in all directions. Finding all right, it would scratch upon the smooth blanket on which I was playing with it as if to make a hole, then hammer with the nut between its teeth upon the blanket, and finally perform all the motions required to fill up a hole—*in the air;* after which it would jump away, leaving the nut, of course, uncovered."—JAMES *Psychology*, vol. ii, ch. 24, p. 400. (H. H. & Co., 1899.)

377. BLOOD-BROTHERHOOD—*A Symbol of Duty and Truth Owed Only to Kindred.*—In the old days, before there were lawyers and law-books, solemn acts and rights were made plain to all men by picturesque ceremonies suited to lay hold of unlettered minds. Many of these old ceremonies are still kept up and show their meaning as plainly as ever. For example, when two parties wish to make firm peace or friendship, they will go through the ceremony of mixing their blood, so as to make themselves blood-relations. Travelers often now ally themselves in such blood-brotherhood with barbarous tribes; an account of East Africans performing the rite describes the two sitting together on a hide so as to become "of one skin," and then they made little cuts in one another's breasts, tasted the mixed blood, and rubbed it into one another's wounds. Thus we find still going on in the world a compact which Herodotus describes among the ancient Lydians and Scythians, and which is also mentioned in the sagas of the old Northmen and the ancient Irish legends. It would be impossible to put more clearly the great principle of old-world morals, that a man owes friendship not to mankind at large, but only to his own kin, so that to entitle a stranger to kindness and good faith he must become a kinsman by blood. With much the same thought even rude tribes hold that eating and drinking together is a covenant of friendship, for the guest becomes in some sort one of the household, and has to be treated as morally one of the family. This helps to explain the vast importance people everywhere give to the act of dining together.—TYLOR *Anthropology*, ch. 16, p. 423. (A., 1899.)

378. BLOOD, CAUSE OF COLOR OF—*Work of the Red Corpuscles—"The Life of All Flesh Is the Blood" (Lev. xvii, 14).*—When a very thin film of blood is placed under a microscope of sufficient power, we observe that, so far from being a uniformly red fluid, blood is really as colorless as water. This apparent paradox between what we see with the unassisted sight and

what is beheld under the microscope is entirely explained when we discover that the red color of blood is due, not to any inherent property of color in blood as a fluid, but to the enormous number of red particles which float in it. What the microscope enables us to see is the clear liquid between the red particles it bears. To the naked eye, which is unable to distinguish minute objects, and which sees things only in the mass, as it were, blood naturally appears red. In any case, it will take its color from its floating particles.

Some worms have green blood; this is due to the green hue of their blood particles. An oyster or a lobster has colorless blood because it possesses no colored particles at all, but only white or colorless ones. The blood-particles we name "corpuscles"; and in addition to the red ones seen in our blood there are also white corpuscles. The latter are less numerous than the red, and we may calculate that about one white to 400 or 500 red corpuscles is to be taken as a fair or average estimate of their proportion. The red corpuscles of the blood discharge a very important duty in the maintenance of our lives. They are the gas-carriers of the blood. They go forth from the lungs laden with the oxygen we have breathed in; they return to the lungs charged with the carbonic acid gas which we have to breathe out. So far, then, the use and duty of the millions of red particles in our blood are not by any means matters of doubt.—Andrew Wilson *Glimpses of Nature*, ch. 23, p. 74. (Hum., 1892.)

379. BLOOD-LETTING THE ONCE UNIVERSAL CURE — *Patients Reduced To Keep Down Fever.*—The doctrine of vital force entered into the pathological system of changes in irritability. The attempt was made to separate the direct actions of the virus which produce disease, in so far as they depended on the play of blind natural forces, the *symptomata morbi*, from those which brought on the reaction of vital force, the *symptomata reactionis*. The latter were principally seen in inflammation and in fever. It was the function of the physician to observe the strength of this reaction, and to stimulate or moderate it according to circumstances.

The treatment of fever seemed at that time to be the chief point; to be that part of medicine which had a real scientific foundation, and in which the local treatment fell comparatively into the background. The therapeutics of febrile diseases had thereby become very monotonous, altho the means indicated by theory were still abundantly used, and especially blood-letting, which since that time has almost been entirely abandoned.—Helmholtz *Popular Lectures*, lect. 5, p. 217. (L. G. & Co., 1898.)

380. BLOOD POURS TO BRAIN DURING MENTAL ACTIVITY—*Muscles Drained To Supply Higher Life.*—Mosso . . . discovered that the blood-supply to the arms diminished during intellectual activity, and found furthermore that the arterial tension (as shown by the sphygmograph) was increased in these members. . . . The brain itself is an excessively vascular organ, a sponge full of blood, in fact; and another of Mosso's inventions showed that when less blood went to the arms, more went to the head. The subject to be observed lay on a delicately balanced table which could tip downward either at the head or at the foot if the weight of either end were increased. The moment emotional or intellectual activity began in the subject, down went the balance at the head-end, in consequence of the redistribution of blood in his system. But the best proof of the immediate afflux of blood to the brain during mental activity is due to Mosso's observations on three persons whose brain had been laid bare by lesion of the skull. By means of apparatus described in his book, this physiologist was enabled to let the brain-pulse record itself directly by a tracing. The intracranial blood-pressure rose immediately whenever the subject was spoken to, or when he began to think actively, as in solving a problem in mental arithmetic.—James *Psychology*, vol. i, ch. 3, p. 97. (H. H. & Co., 1899.)

381. BLOOD, THE AVENGER OF — *Crude Barbaric Justice—Hebrew Limitation of Ancient Custom.*—When in barbaric life fierce passion breaks loose and a man is slain, this rule of vengeance comes into action. How it works as one of the great forces of society may well be seen among the Australians. As Sir George Grey says in his account of it, the holiest duty a native is called on to perform is to avenge the death of his nearest relation. If he left this duty unfulfilled, the old women would taunt him; if he were unmarried, no girl would speak to him; if he had wives, they would leave him; his mother would cry and lament that she had given birth to so degenerate a son, his father would treat him with contempt, and he would be a mark for public scorn. But what is to be done if the murderer escapes, as must in so wild and thinly peopled a country be easy? Native custom goes on the ancient doctrine that the criminal's whole family are responsible; so that when it is known that a man has been slain, and especially when the actual culprit has escaped, his kinsfolk run for their lives; the very children of seven years old know whether they are of kin to the manslayer, and, if so, they are off at once into hiding. Here, then, we come in view of two principles which every student of law should have clearly in his mind in tracing its history up from its lowest stages. In the primitive law of vengeance of blood, he sees society using for the public benefit the instinct of revenge which man has in common with the lower animals; and by hold-

ing the whole family answerable for the deed of one of its members, the public brings the full pressure of family influence to bear on each individual as a means of keeping the peace. No one who sees the working of blood-vengeance can deny its practical reasonableness, and its use in restraining men from violence while there are as yet no judges and executioners. Indeed among all savages and barbarians the avenger of blood, little as he thinks it himself in his wild fury, is doing his part toward saving his people from perishing by deeds of blood.—TYLOR *Anthropology,* ch. 16, p. 414. (A., 1899.)

382. BLOOM AMID DESOLATION—*Alpine Flowers in the Midst of Ice and Snow.*—There are valleys in the Alps far above six thousand feet which have no glaciers, and where perpetual snow is seen only on their northern sides. These contrasts in temperature lead to the most wonderful contrasts in the aspect of the soil; summer and winter lie side by side, and bright flowers look out from the edge of snows that never melt. Where the warm winds prevail there may be sheltered spots at a height of ten or eleven thousand feet, isolated nooks opening southward where the most exquisite flowers bloom in the midst of perpetual snow and ice; and occasionally I have seen a bright little flower with a cap of snow over it that seemed to be its shelter. The flowers give, indeed, a peculiar charm to these high Alpine regions. Occurring often in beds of the same kind, forming green, blue, or yellow patches, they seem nestled close together in sheltered spots, or even in fissures and chasms of the rock, where they gather in dense quantities. Even in the sternest scenery of the Alps some sign of vegetation lingers. I remember to have found a tuft of lichen growing on the only rock which pierced through the ice on the summit of the Jungfrau.—AGASSIZ *Geological Sketches,* ser. i, ch. 8, p. 226. (H. M. & Co., 1896.)

383. BLOSSOMS OF THE FROST—*Hidden Law Binding Water Crystals to the Angle of Sixty Degrees.*—There is hardly a more beautiful and instructive example of this play of molecular force than that furnished by the case of water. You have seen the exquisite fernlike forms produced by the crystallization of a film of water on a cold window-pane. You have also probably noticed the beautiful rosettes tied together by the crystallizing force during the descent of a snow-shower on a very calm day. The slopes and summits of the Alps are loaded in winter with these blossoms of the frost. They vary infinitely in detail of beauty, but the same angular magnitude is preserved throughout: an inflexible power binding spears and spiculæ to the angle of 60°. The common ice of our lakes is also ruled in its deposition by the same angle. You may sometimes see in freezing water small crystals of stellar shapes, each star consisting of six rays, with this angle of 60° between every two of them. This structure may be revealed in ordinary ice. In a sunbeam, or, failing that, in our electric beam, we have an instrument delicate enough to unlock the frozen molecules without disturbing the order of their architecture. Cutting from clear, sound, regularly frozen ice a slab parallel to the planes of freezing, and sending a sunbeam through such a slab, it liquefies internally at special points, round each point a six-petaled liquid flower of exquisite beauty being formed. Crowds of such flowers are thus produced.—TYNDALL *Lectures on Light,* lect. 3, p. 106. (A., 1898.)

384. BLUE OF SKY ARTIFICIALLY PRODUCED—*Light Separates Atoms from Gas*—*Blue of Sky Results.*—Sulfur and oxygen combine to form sulfurous acid gas, two atoms of oxygen and one of sulfur constituting the molecule of sulfurous acid. It has been recently shown that waves of ether issuing from a strong source, such as the sun or the electric light, are competent to shake asunder the atoms of gaseous molecules. A chemist would call this "decomposition" by light; but it behooves us, who are examining the power and function of the imagination, to keep constantly before us the physical images which underlie our terms. Therefore I say, sharply and definitely, that the components of the molecules of sulfurous acid are shaken asunder by the ether-waves. Enclosing sulfurous acid in a suitable vessel, placing it in a dark room, and sending through it a powerful beam of light, we at first see nothing: the vessel containing the gas seems as empty as a vacuum. Soon, however, along the track of the beam a beautiful sky-blue color is observed, which is due to light scattered by the liberated particles of sulfur.—TYNDALL *Fragments of Science,* vol. ii, ch. 8, p. 120. (A., 1897.)

385. BLUNDER ATTRIBUTED TO NATURE—*The Sloth as Characterized by Buffon*—*A Supposed "Defective Monster."*—"The inertia of this animal is not so much due to laziness as to wretchedness; it is the consequence of its faulty structure. . . . Inactivity, stupidity, and even habitual suffering result from its strange and ill-constructed conformation. Having no weapons for attack or defense, no mode of refuge even by burrowing, its only safety is in flight. Confined within the narrowest range, only climbing with difficulty or dragging itself along painfully, never allowing its plaintive voice to be heard except at night, everything about it shows its wretchedness and proclaims it to be one of those defective monsters, those imperfect sketches, which Nature has sometimes formed, and which, having scarcely the faculty of existence,

could only continue for a short time and have since been removed from the catalog of living beings. . . . To regard these imperfect sketches of animal life as being as good as others, to admit final causes for such ill-proportioned creatures, and to find that Nature is as admirable in them as in her finest works, is to take a most narrow view of the world and make our own ideas of finality the tests of Nature's aims."

In this quotation we have a memorable example of the errors into which the greatest thinkers may sometimes fall. It records a rash judgment (with respect to the sloth) which the illustrious zoologist Buffon allowed himself to make, and which he has recorded in the thirteenth volume of his immortal "Natural History."—MIVART *Types of Animal Life*, ch. 9, p. 246. (L. B. & Co., 1893.)

386. BODIES, CELESTIAL, VIEWED AS ABODES OF SENTIENT BEINGS— *General Belief that Other Worlds Are Inhabited.*—In fact, it is in this way that we view all the celestial bodies. We are not contented when studying the sun, for example, with the mere consideration of the wonderful processes taking place upon his surface and around him; but we inquire how these processes are related to his power of supplying our wants, and the wants of all that live upon the earth, by means of the light and heat which he emits. We study our moon in the same spirit; we see that, whether she be herself inhabited or not, she was not created in vain—she rules our tides, she gives us an important tho intermitting supply of light by night, she serves as a measure of time, she helps to guide the seaman over the trackless waves of ocean, and she subserves our wants in a variety of other ways. And it is the same method of viewing the celestial bodies which has led nearly all men to believe in the existence of multitudes of other worlds than ours.—PROCTOR *Expanse of Heaven*, p. 85. (L. G. & Co., 1897.)

387. BODY AND MIND TRAINED IN UNISON BY THE GREEKS — To the Greeks the idea that the human being consists of two halves whose prerogatives are unequal was wholly foreign; they made the equilibrium between the intellectual and the physical life the groundwork of education. As a consequence, even their culture of the physical life was of a character to cultivate the mind. The greatest possible comprehensiveness of exercise, systematically directed, enlivened by music and combat, was calculated to contribute to the elasticity and activity of the body, to endurance in running and in wrestling, and also to bestow a firm, light step, a free, spirited carriage, the freshness of health, and a clear, unshrinking eye; while stimulating the mental power to prudence and manly self-assertion, and to presence of mind; in fact, to become possessed of the kind of virtues that should distinguish the noble and well bred from the low and uncultivated, the free citizen loving his country from those of servile spirit, egoistic, who think of nothing but material gain.—KÜPPERS *Der Apoxyomenos des Lysippos und die griechische Palästre.* (Translated for *Scientific Side-Lights.*)

388. BODY A WONDERFUL CONTRIVANCE OF CREATIVE SKILL—*Not an Object of Contempt.*—I have no wish whatever to exalt unduly the body; I have, if possible, still less desire to degrade the mind; but I do protest, with all the energy I dare use, against the unjust and most unscientific practise of declaring the body vile and despicable, of looking down upon the highest and most wonderful contrivance of creative skill as something of which man dare venture to feel ashamed.—MAUDSLEY *Body and Mind*, lect. 3, p. 95. (A., 1898.)

389. BODY, MEDIEVAL CONTEMPT FOR—*Regarded as "Prison-house" of the Spirit—False Views of Insanity.*—[Under the medieval philosophy] the body was looked down upon with contempt, as vile and despicable, the temple of Satan, the home of the fleshly lusts which war against the soul, and as needing to be vigilantly kept in subjection, to be crucified daily with its affections and lusts. It was the earthly prison-house of the spirit whose pure immortal longings were to get free from it. Such was the monstrous doctrine of the relation of mind and body. What place could a rational theory of insanity have in such an atmosphere of thought and feeling? The conception of it as a disease was impossible: it was ascribed to a supernatural operation, divine or diabolical, as the case might be—was a real possession of the individual by some extrinsic superior power.—MAUDSLEY *Body and Mind*, lect. 4, p. 101. (A., 1898.)

390. BODY OF MAN A MACHINE— *Descartes's Illustration of a Bathing Diana —Mind the Engineer Controlling the Mechanism.*—Thus, as you may have seen in the grottoes and the fountains in royal gardens, the force with which the water issues from its reservoir is sufficient to move various machines, and even to make them play instruments, or pronounce words according to the different disposition of the pipes which lead the water. And, in truth, the nerves of the machine which I am describing may very well be compared to the pipes of these water-works; its muscles and its tendons to the other various engines and springs which seem to move them; its animal spirits to the water which impels them, of which the heart is the fountain; while the cavities of the brain are the central office. Moreover, respiration and other such actions as are natural and usual in the body, and which depend on the course of the spirits, are like the movements of a clock, or of a mill, which may be kept up by the

ordinary flow of the water. The external objects which, by their mere presence, act upon the organs of the senses; and which, by this means, determine the corporal machine to move in many different ways, according as the parts of the brain are arranged, are like the strangers who, entering into some of the grottoes of these waterworks, unconsciously cause the movements which take place in their presence. For they cannot enter without treading upon certain planks so arranged that, for example, if they approach a bathing Diana, they cause her to hide among the reeds; and if they attempt to follow her, they see approaching a Neptune, who threatens them with his trident; or if they try some other way, they cause some monster, who vomits water into their faces, to dart out; or like contrivances, according to the fancy of the engineers who have made them. And lastly, when the rational soul is lodged in this machine, it will have its principal seat in the brain, and will take the place of the engineer, who ought to be in that part of the works with which all the pipes are connected, when he wishes to increase or to slacken, or in some way to alter, their movements.—HUXLEY *Lay Sermons*, serm. 14, p. 322. (G. P. P., 1899.)

391. ——— ——— *Inscrutable Mystery of Life—Personality.*—All investigation goes to show that in a mechanical sense the body of an animal is only a very ingenious and effective machine, by means of which the living inhabitant which controls it can utilize the energy derived from the food taken into the stomach. The body, regarded as a mechanism, is only a food-engine in which the stomach and the lungs stand for the furnace and boiler of a steam-engine, the nervous system for the valve-gear, and the muscles for the cylinder. How the personality within, which wills and acts, is put into relation with this valve-gear, so as to determine the movements of the body it resides in, is the inscrutable mystery of life; the facts in the case, however, being no less facts because inexplicable.—YOUNG *The Sun*, int., p. 3. (A., 1898.)

392. BODY, THE HUMAN, MECHANICAL FUNCTIONS OF—*Involuntary Closing of the Eye.*—Consider what happens when a blow is aimed at the eye. Instantly, and without our knowledge or will, and even against the will, the eyelids close. What is it that happens? A picture of the rapidly advancing fist is made upon the retina at the back of the eye. The retina changes this picture into an affection of a number of the fibers of the optic nerve; the fibers of the optic nerve affect certain parts of the brain; the brain, in consequence, affects those particular fibers of the seventh nerve which go to the orbicular muscle of the eyelids; the change in these nerve-fibers causes the muscular fibers to change their dimensions, so as to become shorter and broader; and the result is the closing of the slit between the two lids round which these fibers are disposed. Here is a pure mechanism, giving rise to a purposive action, and strictly comparable to that by which Descartes supposes his water-work Diana [see BODY OF MAN, 390] to be moved. But we may go further, and inquire whether our volition, in what we term voluntary action, ever plays any other part than that of Descartes's engineer, sitting in his office, and turning this tap or the other, as he wishes to set one or another machine in motion, but exercising no direct influence upon the movements of the whole.—HUXLEY *Lay Sermons*, serm. 14, p. 335. (G. P. P., 1899.)

393. BOMBARDMENT BY MOLECULES—*Expansion and Contraction Explained.*—According to this theory, which is known as the Kinetic Theory of gases, we are to figure the molecules of a gas as flying in straight lines through space, impinging like little projectiles upon each other, and striking against the boundaries of the space they occupy. I place a bladder, half filled with air, under the receiver of the air-pump, and remove the air from the receiver. The bladder swells. According to our present theory, this expansion of the bladder is produced by the shooting of atomic projectiles against its interior surface. When air is admitted into the receiver, the bladder shrivels to its former size; and here we must figure the discharge of the atoms against the outer surface of the bladder, driving the envelope inwards, causing, at the same time, the atoms within to concentrate their fire, until finally the force from within equals that from without, and the envelope remains quiescent. All the impressions, then, which we derive from heated air or vapor are, according to this hypothesis, due to the impact of gaseous molecules. Thus the impression one receives on entering the hot-room of a Turkish bath is caused by the atomic patter there maintained against the surface of the body.—TYNDALL *Heat a Mode of Motion*, lect. 5, p. 118. (A., 1900.)

394. BONDAGE OF FACT—*Science Must Master Details.*—The bondage under which all true science lies to fact—the necessity of groping among the detail of little and common things—this is a hard lesson for the human intellect to learn—conscious as that intellect is of its own great powers—of its own high aims—of its own large capacities of intuitive understanding. But it is a lesson which must be learned. There are no short cuts in Nature. Her results are always attained by method. Her purposes are always worked out by law. So must ours be. For our bodies and our spirits are both parts of the great order of Nature; and our wills can attain no end, and can ac-

complish no design, except through knowledge and through use of the appropriate and appointed means. Nor can those means be ascertained except by careful observation, and as careful reasoning. It is a hard thing to know all the forces which operate even on our own individual minds; and it is a much harder problem to understand the forces which arise out of the complicated conditions of human society.—ARGYLL *Reign of Law,* ch. 7, p. 197. (Burt.)

395. BOW, THE, A PREHISTORIC WEAPON—*Stone Arrow-heads Prove Antiquity.*—However invented, the bow came into use in ages before history. Its arrow is a miniature of the full-sized javelin, and the old stone arrow-heads found in most regions of the world show the existence of the bow and arrow in the Stone Age, tho hardly back to the drift period. The art of feathering the arrow goes back as far as history, and we know not how much further.—TYLOR *Anthropology,* ch. 8, p. 195. (A., 1899.)

396. BRAIN, ACTIVITY OF, PRODUCES LOCAL HEAT—*Anger Really a Hot Passion—Great Strain of Silent Recitation.*—Brain-activity seems accompanied by a local disengagement of heat. . . . Dr. J. S. Lombard . . . found [in more than 60,000 observations] that any intellectual effort, such as computing, composing, reciting poetry silently or aloud, and especially that emotional excitement such as an anger fit, caused a general rise of temperature, which rarely exceeded a degree Fahrenheit. The rise was in most cases more marked in the middle region of the head than elsewhere. Strange to say, it was greater in reciting poetry silently than in reciting it aloud. Dr. Lombard's explanation is that "in internal recitation an additional portion of energy, which in recitation aloud was converted into nervous and muscular force, now appears as heat." I should suggest rather, if we must have a theory, that the surplus of heat in recitation to oneself is due to inhibitory processes which are absent when we recite aloud. . . . The simple central process is to speak when we think; to think silently involves a check in addition.—JAMES *Psychology,* vol. i, ch. 3, p. 99. (H. H. & Co., 1899.)

397. BRAIN BENUMBED BY HEAT—*Effect of Molecular Motion.*—But what is heat, that it should work such changes in moral and intellectual nature? Why are we unable to read "Mill's Logic" or study the "Kritik der reinen Vernunft" with any profit in a Turkish bath? Heat, defined without reference to our sensations, is a kind of motion, as strictly mechanical as the waves of the sea, or as the aerial vibrations which produce sound. The communication of this motion to the molecules of the brain produces the moral and intellectual effects just referred to. Human action is only possible within a narrow zone of temperature. Transgress the limit on one side, and we are torpid by excess; transgress it on the other, and we are torpid by defect. The intellect is in some sense a function of temperature. Thus at noon we were drained of intellectual energy; eight hours later the mind was awake and active, and through her operations was shed that feeling of earnestness and awe which the mystery of the starry heavens ever inspires. Physically considered, however, the intellect of noon differed from that of 8 p. m. simply in the amount of motion possessed by the molecules of the brain.—TYNDALL *Hours of Exercise in the Alps,* ch. 5, p. 61. (A., 1898.)

398. BRAIN, HEMISPHERES OF, SPECIALIZED — *Right-handed People Are Left-brained.*—Most people, in fact, are left-brained, that is, all their delicate and specialized movements are handed over to the charge of the left hemisphere. The ordinary right-handedness for such movements is only a consequence of that fact, a consequence which shows outwardly on account of that extensive decussation of the fibers whereby most of those from the left hemisphere pass to the right half of the body only.—JAMES *Psychology,* vol. i, ch. 2, p. 39. (H. H. & Co., 1899.)

399. BRAIN NOT INVOLVED IN REFLEX ACTION—*Breathing, the Beating of the Heart, etc., Unconscious—The Highest (Cerebral) Force Economized.*—The reflex actions—breathing, the movements of the intestines, the heart's action, winking, etc. —are known to be stimulated through the spinal cord, and its immediate continuations at the base of the brain; they do not involve the cerebral mass. The responding movements in the case of each of them are limited to the work to be done: to the chest, in breathing; to the intestines, in propelling the food; to the muscles of the heart, in pumping the blood. These actions are unaccompanied with feeling. So, in touching the hand of one asleep, we see the hand curl up, or the arm move away. This is called reflex; it is prompted through the lower centers, without lateral diffusion or communication, and it is directed to a single local group of muscles. In such examples, as formerly seen, the limitation is owing to want of force. There are ways open to the brain; but they are not entered at the instance of a very feeble contact. Still, the fact of limitation of range is accompanied by the fact of unconsciousness: an isolated response is our evidence for contraction of the sphere of excitement; and such isolated responses are little, if at all, accompanied with feeling.—BAIN *Mind and Body,* ch. 4, p. 14. (Hum., 1880.)

400. BRAIN OF MAN AND OF APE—*Absolute and Relative Differences.*—So far as I am aware, no human cranium belonging to an adult man has yet been observed with a

less cubical capacity than 62 cubic inches, the smallest cranium observed in any race of men, by Morton, measuring 63 cubic inches; while, on the other hand, the most capacious gorilla skull yet measured has a content of not more than 34½ cubic inches. Let us assume, for simplicity's sake, that the lowest man's skull has twice the capacity of the highest gorilla.

No doubt this is a very striking difference, but it loses much of its apparent systematic value when viewed by the light of certain other equally indubitable facts respecting cranial capacities.

The first of these is, that the difference in the volume of the cranial cavity of different races of mankind is far greater, absolutely, than that between the lowest man and the highest ape, while, relatively, it is about the same. For the largest human skull measured by Morton contained 114 cubic inches—that is to say, had very nearly double the capacity of the smallest, while its absolute preponderance of 52 cubic inches is far greater than that by which the lowest adult male human cranium surpasses the largest of the gorillas ($62 - 34\frac{1}{2} = 27\frac{1}{2}$). Secondly, the adult crania of gorillas which have as yet been measured differ among themselves by nearly one-third, the maximum capacity being 34.5 cubic inches, the minimum 24 cubic inches; and, thirdly, after making all due allowance for difference of size, the cranial capacities of some of the lower apes fall nearly as much, relatively, below those of the higher apes as the latter fall below man.

Thus, even in the important matter of cranial capacity, men differ more widely from one another than they do from the ape, while the lowest apes differ as much, in proportion, from the highest as the latter does from man. The last proposition is still better illustrated by the study of the modifications which other parts of the cranium undergo in the Simian series.—HUXLEY *Man's Place in Nature*, p. 221. (Hum.)

401. ——— ——— *Difference in Weight of Brain.*—It must not be overlooked, however, that there is a very striking difference in absolute mass and weight between the lowest human brain and that of the highest ape—a difference which is all the more remarkable when we recollect that a full-grown gorilla is probably pretty nearly twice as heavy as a Bosjes man, or as many an European woman. It may be doubted whether a healthy human adult brain ever weighed less than thirty-one or two ounces, or that the heaviest gorilla brain has exceeded twenty ounces. This is a very noteworthy circumstance, and doubtless will one day help to furnish an explanation of the great gulf which intervenes between the lowest man and the highest ape in intellectual power.—HUXLEY *Man's Place in Nature*, p. 231. (Hum.)

402. ——— ——— *Enormous Increase in Human Brain.*—We find the most pronounced distinction between man and the anthropoid apes in the size and complexity of his brain. Thus, Professor Huxley tells us that "it may be doubted whether a healthy human adult brain ever weighed less than 31 or 32 ounces, or that the heaviest gorilla brain has exceeded 20 ounces," altho "a full-grown gorilla is probably pretty nearly twice as heavy as a Bosjes man, or as many an European woman." The average human brain, however, weighs 48 or 49 ounces, and if we take the average ape brain at only 2 ounces less than the very largest gorilla's brain, or 18 ounces, we shall see better the enormous increase which has taken place in the brain of man.—WALLACE *Darwinism*, ch. 15, p. 308. (Hum.)

403. BRAIN OF PRIMITIVE MAN HELD THE POSSIBILITIES OF THE FUTURE—The one endowment that this creature [primitive man] possessed, having in it the promise and potency of all future achievements, was the creative spark called invention. The superabundant brain over and above all the amount required for mere animal existence, held in trust the possibilities of the future, and stamped upon man the divine likeness. This naked ignoramus is the father of the clothed philosopher, looking out into infinite space and time and causation.—MASON *The Birth of Invention, Address at Centenary of Amer. Patent System, Washington, D. C., 1891*, (procs.) p. 405.

404. BRAIN, THE ESSENTIAL ORGAN OF KNOWLEDGE—*Results of Changes in.*—The experiences of the body are one of the conditions of the faculty of memory being what it is. And . . . the brain is the part whose experiences are directly concerned. If the nervous communication be cut off between the brain and other parts, the experiences of those other parts are non-existent for the mind. The eye is blind, the ear deaf, the hand insensible and motionless. And conversely, if the brain be injured, consciousness is abolished or altered, even altho every other organ in the body be ready to play its normal part. A blow on the head, a sudden subtraction of blood, the pressure of an apoplectic hemorrhage, may have the first effect; whilst a very few ounces of alcohol or grains of opium or hasheesh, or a whiff of chloroform or nitrous oxid gas, are sure to have the second. The delirium of fever, the altered self of insanity, are all due to foreign matters circulating through the brain, or to pathological changes in that organ's substance.—JAMES *Psychology*, vol. i, ch. 1, p. 4. (H. H. & Co., 1899.)

405. BREAD CONTAINS FEW BACTERIA—*The Universal Food Relatively Pure.*—Bread forms an excellent medium for molds, but unless specially exposed the bacteria in it are few. Waldo and Walsh have,

however, demonstrated that baking does not sterilize the interior of bread. These observers cultivated numerous bacteria from the center of newly baked London loaves. The writer has recently made a series of examinations of the air of several underground bakehouses in central London; but, tho the air was highly impregnated with flour-dust, few bacteria were present. —NEWMAN *Bacteria*, ch. 6, p. 239. (G. P. P., 1899.)

406. BRIGHTNESS THAT ONLY DARKNESS AND GLOOM REVEAL—*Sun's Chromosphere and Corona Seen Only in Eclipse.*—But what a marvelous spectacle is then afforded to all eyes directed to the same point of the sky! In place of the sun appears a black disk, surrounded by a glorious crown of light. In this ethereal crown we see immense rays diverging from the eclipsed sun. Rose-colored flames appear to issue from the lunar screen which masks the god of day. During two minutes, three minutes, four minutes, the astronomer studies this strange frame, rendered visible by the passage of the moon before the radiant disk, while the people, surprised and still silent, seem to await with anxiety the end of a spectacle which they have never seen before and may never see again. Suddenly a jet of light, a shout of pleasure from a thousand throats, announces the return of the joyous sun, still pure, still luminous, still fiery, still faithful.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 9, p. 197. (A.)

407. BRILLIANCY A MEANS OF CONCEALMENT—*The White-headed Fruit-pigeon.*—In some cases the concealment is effected by colors and markings which are so striking and peculiar that no one who had not seen the creature in its native haunts would imagine them to be protective. An example of this is afforded by the banded fruit-pigeon of Timor, whose pure white head and neck, black wings and back, yellow belly, and deeply curved black band across the breast, render it a very handsome and conspicuous bird. Yet this is what Mr. H. O. Forbes says of it: "On the trees the white-headed fruit-pigeon (*Ptilopus cinctus*) sat motionless during the heat of the day in numbers, on well-exposed branches; but it was with the utmost difficulty that I or my sharp-eyed native servant could ever detect them, even in trees where we knew they were sitting." The trees referred to are species of Eucalyptus which abound in Timor. They have whitish or yellowish bark and very open foliage, and it is the intense sunlight casting black curved shadows of one branch upon another, with the white and yellow bark and deep blue sky seen through openings of the foliage, that produces the peculiar combination of colors and shadows to which the colors and markings of this bird have become so closely assimilated.—WALLACE *Darwinism*, ch. 8, p. 136. (Hum., 1889.)

408. BRILLIANCY OF COLOR CHARACTERIZES MALE BIRDS—*Mothers Commonly Protected by Modest Colors.*—The most fundamental characteristic of birds, from our present point of view, is a greater intensity of color in the male. . . . In order that the species may be continued, young birds must be produced, and the female birds have to sit assiduously on their eggs. While doing this they are exposed to observation and attack by the numerous devourers of eggs and birds, and it is of vital importance that they should be protectively colored in all those parts of the body which are exposed during incubation. To secure this end all the bright colors and showy ornaments which decorate the male have not been acquired by the female, who often remains clothed in the sober hues which were probably once common to the whole order to which she belongs.—WALLACE *Darwinism*, ch. 10, p. 187. (Hum., 1889.)

409. BROTHERHOOD OF MAN—*A Growing Conviction and Sentiment of the Human Race.*—"If we would indicate an idea which, throughout the whole course of history, has ever more and more widely extended its empire, or which, more than any other, testifies to the much-contested and still more decidedly misunderstood perfectibility of the whole human race, it is that of establishing our common humanity—of striving to remove the barriers which prejudice and limited views of every kind have erected among men, and to treat all mankind, without reference to religion, nation, or color, as one fraternity, one great community, fitted for the attainment of one object, the unrestrained development of the physical powers. This is the ultimate and highest aim of society, identical with the direction implanted by nature in the mind of man toward the indefinite extension of his existence. He regards the earth in all its limits, and the heavens as far as his eye can scan their bright and starry depths, as inwardly his own, given to him as the objects of his contemplation, and as a field for the development of his energies. Even the child longs to pass the hills or the seas which enclose his narrow home; yet, when his eager steps have borne him beyond those limits, he pines, like the plant, for his native soil; and it is by this touching and beautiful attribute of man—this longing for that which is unknown, and this fond remembrance of that which is lost—that he is spared from an exclusive attachment to the present. Thus deeply rooted in the innermost nature of man, and even enjoined upon him by his highest tendencies, the recognition of the bond of humanity becomes one of the noblest leading principles in the history

of mankind." [Quoted from Wilhelm von Humboldt.]—HUMBOLDT *Cosmos*, vol. i, p. 358. (H., 1897.)

410. BUBBLE AND FROG—*Elementary Law Has No Adaptation to Circumstance.*—Blow bubbles through a tube into the bottom of a pail of water, they will rise to the surface and mingle with the air. Their action may again be poetically interpreted as due to a longing to recombine with the mother-atmosphere above the surface. But if you invert a jar full of water over the pail, they will rise and remain lodged beneath its bottom, shut in from the outer air, altho a slight deflection from their course at the outset, or a redescent towards the rim of the jar when they found their upward course impeded, would easily have set them free. Suppose a living frog in the position in which we placed our bubbles of air, namely, at the bottom of a jar of water. The want of breath will soon make him also long to rejoin the mother-atmosphere, and he will take the shortest path to his end by swimming straight upwards. But if a jar full of water be inverted over him, he will not, like the bubbles, perpetually press his nose against its unyielding roof, but will restlessly explore the neighborhood until by redescending again he has discovered a path round its brim to the goal of his desires.—JAMES *Psychology*, vol. i, ch. 1, p. 7. (H. H. & Co., 1899.)

411. BUILDINGS, ANCIENT, UNDERMINED BY WORMS—*Subsidence and Cracking of Walls, Cause of.*—Worms have played a considerable part in the burial and concealment of several Roman and other old buildings in England; but no doubt the washing down of soil from the neighboring higher lands, and the deposition of dust, have together aided largely in the work of concealment. Dust would be apt to accumulate wherever old broken-down walls projected a little above the then existing surface and thus afforded some shelter. The floors of the old rooms, halls, and passages have generally sunk, partly from the settling of the ground, but chiefly from having been undermined by worms; and the sinking has commonly been greater in the middle than near the walls. The walls themselves, whenever their foundations do not lie at a great depth, have been penetrated and undermined by worms, and have consequently subsided. The unequal subsidence thus caused probably explains the great cracks which may be seen in many ancient walls, as well as their inclination from the perpendicular.—DARWIN *Formation of Vegetable Mould*, ch. 4, p. 68. (Hum., 1887.)

412. BUTTRESSES, NATURAL—*Supporting Roots of the Brazilian Pashiúba—Tree Stands as if on Stilts—Strange Result of Struggle for Life.*—My guide put me ashore in one place to show me the roots of the Pashiúba. These grow above ground, radiating from the trunk many feet above the surface, so that the tree looks as if supported on stilts; and a person can, in old trees, stand upright among the roots with the perpendicular stem wholly above his head. It adds to the singularity of their appearance that these roots, which have the form of straight rods, are studded with stout thorns, while the trunk of the tree is quite smooth. The purpose of this curious arrangement is, perhaps, similar to that of the buttress-roots already described—namely, to recompense the tree by root-growth above the soil for its inability, in consequence of the competition of neighboring roots, to extend it underground. The great amount of moisture and nutriment contained in the atmosphere may also favor these growths.—BATES *Naturalist on the River Amazon*, ch. 5, p. 661. (Hum., 1880.)

413. CALCULATION, ANCIENT, BY PEBBLES—*Language Preserves the Story of Early Arithmetic.*—In Africa, negro traders may be seen at market reckoning with pebbles, and when they come to five, putting them aside in a little heap. In the South Sea Islands it has been noticed that people reckoning, when they came to ten, would not put aside a heap of ten things, but only a single bit of coconut stalk to stand for ten, and then a bigger piece when they wanted to represent ten tens or a hundred. Now to us it is plain that this use of different kinds of markers is unnecessary, but all that the reckoner with little stones or beans has to do is to keep separate his unit-heap, his ten-heap, his hundred-heap, etc. This use of such things as pebbles for "counters," which still survives in England among the ignorant, was so common in the ancient world that the Greek word for reckoning was *psêphizein*, from *psêphos*, a pebble, and the corresponding Latin word was *calculare*, from *calculus*, a pebble, so that our word calculate is a relic of very early arithmetic. —TYLOR *Anthropology*, ch. 13, p. 313. (A., 1899.)

414. CALCULATION VERIFIED—*A Fine Test—Utilizing the Moon—Star-colors Proved Real—Varied Glory in Distant Space.*—It was long thought that at least the more strongly marked colors, in the case of small companion stars, were due merely to contrast. But the supposition that the colors seen in double stars are due to contrast has been in several instances completely disposed of, by so arranging matters that one star only of a pair is seen at a time. This can readily be arranged where the stars are not very close, and in a great number of cases it has been found that the small star, seen alone, was really blue or green or purple, as the case might be. The experiment was in one case tried in the case of a very close pair, in a very interesting way. The star in question is the ruddy

Antares, called also the Scorpion's Heart. This star has a minute green companion, far too close to the red primary star to be seen alone by any arrangement of the telescope. But advantage was taken by an eminent observer of the passage of the moon over this star. In a moment or two the moon hid the larger star, leaving the other shining alone, and then it was seen that the small star was unmistakably green.—PROCTOR *Expanse of Heaven*, pp. 220-221. (L. G. & Co., 1897.)

415. CALM OF NATURE — *Supposed Discord of the Elements Lost in Higher Unity.*—The knowledge of the laws of Nature, whether we can trace them in the alternate ebb and flow of the ocean, in the measured path of comets, or in the mutual attractions of multiple stars, alike increases our sense of the calm of Nature, while the chimera so long cherished by the human mind in its early and intuitive contemplations, the belief in a "discord of the elements," seems gradually to vanish in proportion as science extends her empire.—HUMBOLDT *Cosmos*, vol. i, int., p. 42. (H., 1897.)

416. CALMNESS OF SCIENCE—*Relief from Strife and Discord—Fascination of Botany or Astronomy.*—He therefore, who amid the discordant strife of nations would seek intellectual repose, turns with delight to contemplate the silent life of plants, and to study the hidden forces of Nature in her sacred sanctuaries; or, yielding to that inherent impulse which for thousands of years has glowed in the breast of man, directs his mind, by a mysterious presentiment of his destiny, towards the celestial orbs, which, in undisturbed harmony, pursue their ancient and eternal course.—HUMBOLDT *Views of Nature*, p. 21. (Bell, 1896.)

417. CAMEL, CHARACTERISTICS OF —*Stolid Endurance Joined with Limited Intelligence.*—The sole good quality that the camel possesses is his seriousness. His intelligence is very limited, he neither shows love nor hate, he is indifferent to everything that is not food or his young. He is irritated whenever he is obliged to work; if he perceives that his wrath is of no avail he submits to his task with the indifference he brings to everything else. He is vicious and dangerous when he is in a rage; his cowardice has no bounds; the roar of a lion will put an entire caravan to flight. Under such circumstances every camel throws down its charge and flees. The howl of a hyena terrifies it; a monkey, a dog, or even a lizard will put it in a fright. I know of no animal with which it is on friendly terms. The donkey's relation to it is kind enough, but of friendship there is no trace. The horse seems to regard him as the most unsightly animal. For his part, the camel appears to regard all other animals with the same bad humor which he feels toward man.—BREHM *La Vie des Animaux illustré, Mammiferes*, p. 443. (Translated for *Scientific Side-Lights.)*

418. CANDOR OF SCIENTIST—*Change of Opinion with Advancing Knowledge.*—But it is the misfortune of progress that one is forced not only to unlearn a great deal, but, if one has been in the habit of communicating his ideas to others, to destroy much of his own work. I now find myself in this predicament; and after teaching my students for years that the Carboniferous epoch belongs to the Paleozoic or Primary age, I am convinced—and this conviction grows upon me constantly as I free myself from old prepossessions and bias on the subject—that with the Carboniferous epoch we have the opening of the Secondary age in the history of the world.—AGASSIZ *Geological Sketches*, ser. i, ch. 5, p. 140. (H. M. & Co., 1896.)

419. CANNIBALISM NOT PRACTISED BY SHELL-MOUND BUILDERS — The observations of Arctic travelers prove that even if human bones had been found in the shell-mounds, this would not of itself be any evidence of cannibalism; but the absence of such remains satisfactorily shows that the primitive population of the North were free from this practise. On the other hand, the tumuli have supplied us with numerous skeletons which probably belong to the Stone Age. The skulls are very round, and in many respects resemble those of the Lapps, but have a more projecting ridge over the eye.—AVEBURY *Prehistoric Times*, ch. 7, p. 229. (A., 1900.)

420. CAPACITY OF VARIATION A CAPACITY OF IMPROVEMENT — No case is on record of a variable organism ceasing to vary under cultivation. Our oldest cultivated plants, such as wheat, still yield new varieties: our oldest domesticated animals are still capable of rapid improvement or modification.—DARWIN *Origin of Species*, ch. 1, p. 6. (Burt.)

421. CAPITAL, VITAL — *The Young Plant Draws on Accumulated Store.*—The food of plants being in great measure the same for all, and bathing all so that it can be absorbed without effort, their vital processes result almost entirely in profit. Once fairly rooted in a fit place, a plant may thus from the outset add a very large proportion of its entire returns to capital; and may soon be able to carry on its processes on a large scale, tho it does not at first do so. When, however, plants are expenders, namely, during their germination and first stages of growth, their degrees of growth are determined by their amounts of vital capital. It is because the young tree commences life with a ready-formed embryo and store of food sufficient to last for some time, that it is enabled to strike root and lift its head above the surrounding herbage.—SPENCER *Biology*, pt. ii, ch. 1, p. 159. (A., 1900.)

422. CARELESSNESS, CAUSE OF DEATH—*Fatal Result of Neglect—Uncleanliness Destroys Infant Life.*—Careless feeding, in conjunction with a warm, dry summer, invariably results in a high death-rate from this cause. These two causes interact upon each other. A warm temperature is a favorable temperature for the growth of the poisonous micro-organism; a dry season affords ample opportunity for its conveyance through the air. Unclean feeding-bottles are obviously an admirable nidus for these injurious bacteria, for in such a resting-place the three main conditions necessary for bacterial life are well fulfilled, viz.: heat, moisture, and pabulum. The heat is supplied by the warm temperature, the moisture and food by the dregs of milk left in the bottle, and the dry air assists in transit.—NEWMAN *Bacteria*, ch. 6, p. 204. (G. P. P., 1899.)

423. CARE OF OFFSPRING AMONG BIRDS—*Intelligence Combined with Devotion.*—The care of the young and their mental and physical development afford us unequal opportunities for the study of bird-character. We may now become acquainted not only with the species, but with individual birds, and at a time when the greatest demands are made upon their intelligence. We may see the seed-eaters gathering insects and perhaps beating them into a pulp before giving them to their nestlings; or we may learn how the doves, high-holes, and humming-birds pump softened food from their crops down the throats of their offspring. The activity of the parents at this season is amazing. Think of the day's work before a pair of chickadees with a family of six or eight fledglings clamoring for food from daylight to dark!—CHAPMAN *Bird-Life*, ch. 6, p. 70. (A., 1900.)

424. CARE OF OFFSPRING INCREASES AS NUMBER DIMINISHES—*Maternal Instinct among Birds—Division of Labor among Them—Man's Single and Costly Infancy.*—With birds, the necessity of maintaining a high temperature for the eggs leads to the building of nests, to a division of labor in the securing of food, to the development of a temporary maternal instinct, and to conjugal alliances which in some birds last for a lifetime. As the eggs become effectively guarded the number diminishes, till instead of millions there are half a dozen. When it comes to her more valuable products Nature is not such a reckless squanderer after all. So with mammals, for the most part the young are in litters of half a dozen or so; but in man, with his prolonged and costly infancy, parental care reaches its highest development and concentration in rearing children one by one.—FISKE *Through Nature to God*, pt. ii, ch. 11, p. 118. (H. L. & Co., 1900.)

425. CASTS OF VANISHED REMAINS—*Mold of Skeleton Preserved in Rock.*—I have had occasion to work out the nature of fossil remains of which there was nothing left except casts of the bones, the solid material of the skeleton having been dissolved out by percolating water. It was a chance, in this case, that the sandstone happened to be of such a constitution as to set, and to allow the bones to be afterward dissolved out, leaving cavities of the exact shape of the bones. Had that constitution been other than what it was, the bones would have been dissolved, the layers of sandstone would have fallen together into one mass, and not the slightest indication that the animal had existed would have been discoverable.—HUXLEY *American Addresses*, lect. 2, p. 45. (A., 1898.)

426. CAUSALITY, THE IDEA OF, INHERENT IN MAN—*Science Springs from the Search for Causes.*—All our notions of Nature, however exalted or however grotesque, have some foundation in experience. The notion of personal volition in Nature had this basis. In the fury and the serenity of natural phenomena the savage saw the transcript of his own varying moods, and he accordingly ascribed these phenomena to beings of like passions with himself, but vastly transcending him in power. Thus the notion of causality—the assumption that natural things did not come of themselves, but had unseen antecedents—lay at the root of even the savage's interpretation of Nature. Out of this bias of the human mind to seek for the antecedents of phenomena all science has sprung.—TYNDALL *Lectures on Light*, lect. 1, p. 4. (A., 1898.)

427. CAUSATION, PERSONAL, AN ULTIMATE FACT OF CONSCIOUSNESS—*Force, as Known to Man, Connected with Conscious Mind.*—There is a philosophy which has fully as true and as broad a basis in man's psychical experience as can be claimed for the fabric of physical science; and in the admirable words of the great master I have already quoted (Sir John Herschel, in his "Familiar Lectures on Scientific Subjects," p. 460), I shall sum up an argument which this paper is intended rather to illustrate and enforce by an appeal to the familiar facts of consciousness than to present in strict logical form:

"In the mental sense of effort, clear to the apprehension of every one who has ever performed a voluntary act, which is present at the instant when the determination to do a thing is carried out into the act of doing it, we have a consciousness of immediate and personal causation which cannot be disputed or ignored. And when we see the same kind of act performed by another, we never hesitate in assuming for him that consciousness which we recognize in ourselves; and in this case we can verify our conclusion by oral communication." "In the only case in which we are admitted into any personal knowledge of the origin of force, we find it connected (possibly by intermediate links untraceable by our faculties, yet

indisputably connected) with volition, and by inevitable consequence, with motive, with intellect, and with all those attributes of mind in which personality consists."—CARPENTER *Nature and Man*, lect. 12, p. 363. (A., 1889.)

428. CAUSE AND EFFECT IN MENTAL PHENOMENA — *Law in Realm of Mind.*—When we pass from the phenomena of matter to the phenomena of mind, we do not pass from under the reign of law. Here, too, facts do range themselves in an observed order; here, too, there is a chain of cause and effect running throughout all events; here, too, we see around us, and feel within us, the work of forces which have always a certain definite tendency to produce certain definite results; here, too, it is by combination and adjustment among these forces that they are mutually held in check; here, too, accordingly, special ends can only be accomplished by the use of special means.—ARGYLL *Reign of Law*, ch. 6, p. 163. (Burt.)

429. CAUSE AND EFFECT, TESTS OF—*Change of Result Corresponding to Change of Agency.*—The dependence of one thing upon another is ordinarily shown by two classes of facts—the first, the presence of the cause followed by the presence of the effect; the second, the absence of the cause followed by the absence of the effect; as when we prove that lighting a fire is the cause of smoke, or oxygen the cause of putrefaction and decay. Of the two methods, the second—the absence of the cause followed by the absence of the effect—is the most decisive; the preservation of meat by excluding air is the best proof that air, or some ingredient of it, is the cause of putrefaction. More especially convincing is the abrupt removal of a supposed cause, leading at once to the suspension of an effect. There are cases, however, where we cannot make the experiment of removing an agent. We cannot get away from the earth where we live. We cannot remove the moon from its sphere, so as to see what actions on the earth depend upon it; we cannot by an abrupt suspension of lunar gravitation prove that the tides are very largely dependent on lunar influence. For such cases, recourse is had to a third expedient, which happily solves the difficulty, and furnishes the proof required. If the agency in question, altho irremovable, passes through gradations whose amount can be measured, we are able to observe whether the effect has corresponding changes of degree; and if a strict concomitance is observable between the intensity of the cause and the intensity of the effect, we have a presumption that may rise to positive proof of the connection. It is thus shown that the tides depend on the moon and the sun conjointly; that the gaseous and liquid states of matter are due to heat.—BAIN *Mind and Body*, ch. 3, p. 5. (Hum., 1880.)

430. CAUSE BEHIND CAUSE—*Subterranean Forces Built the Mountains—Rain, Snow, Frost, and Rivers Carved Them into Shape.*—We are led by recent geological investigations to reject the notions which were formerly accepted, by which mountain ranges were supposed to be suddenly and violently upheaved by volcanic forces. . . . The actual forms of the mountain ranges are due directly to the action of denuding forces, which have sculptured out from the rude rocky masses all the varied outlines of peaks and crags, of ravines and valleys. But it is none the less true that the determining causes which have directed and controlled all this earth-sculpture are found in the relative positions of hard and soft masses of rock; but these rock-masses have acquired their hardness and consistency, and have assumed their present positions, in obedience to the action of subterranean forces. Hence we see that tho the formation of mountain ranges is proximately due to the denuding forces, which have sculptured the earth's surface, the primary cause for the existence of such mountain chains must be sought for in the fact that subterranean forces have been at work, folding, crumpling, and hardening the soft sediments, and placing them in such positions that, by the action of denudation, the more indurated portions are left standing as mountain masses above the general surface.—JUDD *Volcanoes*, ch. 10, p. 290. (A., 1899.)

431. CAUSE BEHIND THE PRIMORDIAL GERM — In the case of Mr. Darwin, observation, imagination, and reason combined have run back with wonderful sagacity and success over a certain length of the line of biological succession. Guided by analogy, in his "Origin of Species" he placed at the root of life a primordial germ, from which he conceived the amazing variety of the organisms now upon the earth's surface might be deduced. If this hypothesis were even true, it would not be final. The human mind would infallibly look behind the germ, and, however hopeless the attempt, would inquire into the history of its genesis.—TYNDALL *Fragments of Science*, vol. ii, ch. 8, p. 127. (A., 1897.)

432. CAUSE DEMANDED BY HUMAN MIND FOR EVERY EFFECT — Every occurrence in Nature is preceded by other occurrences which are its causes, and succeeded by others which are its effects. The human mind is not satisfied with observing and studying any natural occurrence alone, but takes pleasure in connecting every natural fact with what has gone before it, and with what is to come after it.—TYNDALL *Forms of Water*, p. 1. (A., 1899.)

433. CAUSE, FINAL, NEVER FULLY KNOWN—*We See Immediate, Not Ultimate, Purpose.*—When man makes an implement, he knows the purpose for which he makes it

—he knows the function assigned to it in his own intention. But as in making it there are a thousand chips and fragments of material which he casts aside, so in its final use it often produces consequences and results which he did not contemplate or foresee. But in Nature all this is different. Nature has no chips or fragments which she does not put to use; and as on the way to her apparent ends there are no incidents which she did not foresee, so beyond those ends there are no ulterior results which do not open out into new firmaments of design. Of nothing, therefore, can we say with even the probability of truth that we see its final cause; that is to say, its ultimate purpose. All that we can ever see are the facts of adjustment and of function, and these constitute not final but immediate purpose. But a purpose is not less a purpose because other purposes may lie beyond it. And not only can we detect purpose in natural phenomena, but . . . it is very often the only thing about them which is intelligible to us. The how is very often incomprehensible where the why is apparent at a glance. And be this observed, that when purpose is perceived it is a "making plain" to a higher faculty of the mind than the mere sense of order. It is a making plain to reason. It is the reduction of phenomena to that order of thought which is the basis of all other order in the works of man, and which, he instinctively concludes, is the basis also of all order in the works of Nature.—ARGYLL *Reign of Law*, ch. 2, p. 49. (Burt.)

434. CAUSE OF MIGRATION OF BIRDS —*Nesting-season the Controlling Factor—Bird Goes against Appearances.*—Why do birds migrate? It is true that in temperate and boreal regions the return of cold weather robs them of their food, and they retreat southward. But many, in fact most, birds begin their southern journey long before the first fall frost. We have seen that some species start as early as July and August. Furthermore, there are many birds that come to our Gulf and South Atlantic States to nest, and when the breeding season is over they return to the tropics. Surely, a lower temperature cannot be said to compel them to migrate. Even more remarkable than the southward journey in the fall is the northward journey in the spring. Our birds leave their winter homes in the tropics in the height of the tropical spring, when insect and vegetable food is daily increasing. They leave this land of plenty for one from which the snows of winter have barely disappeared, often coming so early that unseasonable weather forces them to retreat.

I believe that the origin of this great pilgrimage of countless millions of birds is to be found in the existence of an annual nesting-season. . . . There is good reason for the belief that the necessity of securing a home in which their young could be reared was, as it still is, the cause of migration.—CHAPMAN *Bird-Life*, ch. 4, p. 58. (A., 1900.)

435. CAUSE, PHYSICAL, OF THE ALPS—*All Earthly Energy Derived from the Sun.*—And as I looked over this wondrous scene towards Mont Blanc, the Grand Combin, the Dent Blanche, the Weisshorn, the Dom, and the thousand lesser peaks which seemed to join in celebration of the risen day, I asked myself, as on previous occasions: How was this colossal work performed? Who chiseled these mighty and picturesque masses out of a mere protuberance of the earth? And the answer was at hand. Ever young, ever mighty—with the vigor of a thousand worlds still within him —the real sculptor was even then climbing up the eastern sky. It was he who raised aloft the waters which cut out these ravines; it was he who planted the glaciers on the mountain slopes, thus giving gravity a plow to open out the valleys; and it is he who, acting through the ages, will finally lay low these mighty monuments, rolling them gradually seaward—

Sowing the seeds of continents to be;

so that the people of an older earth may see mold spread and corn wave over the hidden rocks which at this moment bear the weight of the Jungfrau.—TYNDALL *Hours of Exercise in the Alps*, ch. 17, p. 190. (A., 1898.)

436. CAUSE, SAME, PRODUCES UNLIKE EFFECTS—*Dew and Frost Results of Radiation.*—It is thus that dew is produced. By the effect of nocturnal radiation bodies exposed in the open air are cooled down, and this cooling condenses on them the vapor of water diffused in the atmosphere. Dew does not descend from the sky, nor does it rise from the earth. A light covering, a sheet of paper, a cloud, is sufficient to check the radiation and prevent dew, as it would prevent frost.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 8, p. 175. (A.)

437. CAUSE SEEN IN LEAST EFFECT —*Motions of Stars Overwhelm Thought.*—In the falling of a rock from a mountain-head, in the shoot of an avalanche, in the plunge of a cataract, we often see more impressive illustrations of the power of gravity than in the motions of the stars. When the intellect has to intervene, and calculation is necessary to the building up of the conception, the expansion of the feelings ceases to be proportional to the magnitude of the phenomena.—TYNDALL *Hours of Exercise in the Alps*, ch. 20, p. 251. (A., 1898.)

438. CAUSE, THE HIGHEST WORK OF SCIENCE TO FIND—*Three Departments of Scientific Study—Observation; Experiment, Theory.*—In the house of science are many mansions, occupied by tenants of diverse kinds. Some of them execute with painstaking fidelity the useful work of ob-

servation, recording from day to day the aspects of Nature, or the indications of instruments devised to reveal her ways. Others there are who add to this capacity for observation a power over the language of experiment, by means of which they put questions to Nature, and receive from her intelligible replies. There is, again, a third class of minds, that cannot rest content with observation and experiment, whose love of causal unity tempts them perpetually to break through the limitations of the senses, and to seek beyond them the roots and reasons of the phenomena which the observer and experimenter record. To such spirits—adventurous and firm—we are indebted for our deeper knowledge of the methods by which the physical universe is ordered and ruled.—TYNDALL *Fragments of Science*, vol. i, ch. 5, p. 131. (A., 1897.)

439. CAUSES, KNOWLEDGE OF, SAVES LIFE—*Bacteria Recognized, Antiseptic Treatment Follows—Surgery Conquers Wounds and Disease.*—Even more important was the introduction of the antiseptic treatment in 1865, which, by preventing the suppuration of incised or wounded surfaces, has reduced the death-rate for serious amputations from forty-five per cent. to twelve per cent., and has besides rendered possible numbers of operations which would have been certainly fatal under the old system. . . . The antiseptic treatment was the logical outcome of the proof that suppuration of wounds and all processes of fermentation and putrefaction were not due to normal changes either in living or dead tissues, but were produced by the growth and the rapid multiplication of minute organisms, especially of those low fungoid groups termed bacteria. If, therefore, we can adopt measures to keep away or destroy these organisms and their germs, or in any way prevent their increase, injured living tissues will rapidly heal. . . . In the case of wounds and surgical operations this is effected by means of a weak solution of corrosive sublimate, in which all instruments and everything that comes in contact with the wound are washed, and by filling the air around the part operated on with a copious spray of carbolic acid.—WALLACE *The Wonderful Century*, ch. 14, p. 148. (D. M. & Co., 1899.)

440. CAUTION NEEDED IN INTERPRETING DISCOVERIES—Stone weapons, however, of many kinds were still in use during the Age of Bronze, and lingered on even into that of iron, so that the mere presence of a few stone implements is not in itself sufficient evidence that any given "find" belongs to the Stone Age.—AVEBURY *Prehistoric Times*, ch. 1, p. 3. (A., 1900.)

441. CAVE-MEN OF DENMARK LIKE MODERN FUEGIANS—*Hunting and Fishing the Great Reliance of Primitive Man.*—The Fuegians wander along their bleak inhospitable shores, feeding mostly on shell-fish, so that in the course of ages their shells, with fish-bones and other rubbish, have formed long banks above high-water mark. Such shell-heaps, or "kitchen-middens," are found here and there all round the coasts of the world, marking the old resorts of such tribes; for instance, on the coast of Denmark, where archeologists search them for relics of rude Europeans, who, in the Stone Age, led a life somewhat like that of Terra del Fuego. Hunting and fishing go on through all levels of society, beginning with the savages who have no other means of subsistence, till at last among civilized nations game and fish hardly do more than supplement the more regular supplies of grain and meat from the farm. Looking at the devices of the hunter and fisher, it will be seen how thoroughly most of them belong to the ruder stages of culture.—TYLOR *Anthropology*, ch. 9, p. 207. (A., 1899.)

442. CAVERNS CARVED BY OCEAN-WAVES—*Fingal's Cave—Remains of Ancient Beaches.*—We are, perhaps, generally disposed to associate the formation of caves with the action of the waves upon a rocky shore, and certainly some of the most remarkable caves are due to this cause. The process of attrition can indeed often be observed in actual progress, and those who have seen the gigantic waves break upon a rock-bound coast, and have observed the huge masses of stone which have been torn away like so many fragments of timber and strewn upon the beach, can form some tolerably accurate idea of the power of the sea to eat its way into the face of any cliff when once it has found a weak place in the rock. . . . [Such is the] familiar cavern known as Fingal's Cave, which is due to the action of the waves. These sea-worn caves are easily distinguished from those formed by other agencies. They are seldom of great extent, and they generally lie in a tolerably horizontal plane. Sometimes they lie far above the present water-line, but the nearly level floor, the indication in their vicinity of an ancient beach, and the fact that in many cases at least similar caves of greater or less extent are to be observed opening on the same general horizon, prove conclusively that they must be due to the prolonged beating of the ocean-waves upon a rocky shore.—DALLAS *Nature-Studies*, p. 37. (Hum., 1888.)

443. CAVES AS READY-MADE HOUSES—*The Cave-men of Europe.*—Rock-shelters under the cliffs were in Europe the resort of the ancient savages, as is proved by the bones and flint flakes and other remains that are found lying there in the ground. Caves are ready-made houses for beast or man. It has been already mentioned how in such countries as England and France caverns were the abodes of the old tribes of the reindeer and mammoth period, and the bushmen of South Africa

are a modern example of rude tribes thus given to dwelling in caves in the rocks. But caverns are so convenient that they are now and then still used in the civilized world, and most of us have seen some cave in a cliff forming the back of a fisherman's cottage, or at least a storehouse.—TYLOR *Anthropology*, ch. 10, p. 229. (A., 1899.)

444. CEDARS OF THE HIMALAYAS—*Timber for the Gods.*—On the Himalayas the acicular-leaved form of trees is distinguished by the mighty thickness and height of the stem as well as by the length of the leaf. The chief ornament of the mountain range is the cedar Deodwara [deodar] *(Pinus Deodara,* Roxb.) [*Cedrus Deodara*], which word is, in Sanskrit, dewa-dâru—*i. e.*, timber for the gods—its stem being nearly from 13 to 14 feet in diameter. It ascends in Nepaul to more than 11,700 feet above the level of the sea. More than 2,000 years ago the Deodwara cedar, near the River Behut—that is, the Hydaspes—furnished the timber for the fleet of Nearchus.—HUMBOLDT *Views of Nature,* p. 317. (Bell, 1896.)

445. CELL, THE FUNDAMENTAL UNIT OF ALL LIVING THINGS—The first of the great fundamental conceptions referred to is the cell theory, which was definitely established for plants in 1838, and immediately afterward for animal structures. The theory is that all the parts and tissues of plants and animals are built up of cells, modified in form and function in an infinite variety of ways, but to be traced in the early stages of growth, alike of bone and muscle, nerve and blood-vessel, skin and hair, root, wood, and flower. And, further, that all organisms originate in simple cells, which are almost identical in form and structure, and which thus constitute the fundamental unit of all living things.—WALLACE *The Wonderful Century,* ch. 14, p. 143. (D. M. & Co., 1899.)

446. ——— ——— *The Constitution of the Ameba.*—The creature which naturalists call the Ameba, one of the lowest in the animal series, consists of nothing but an apparently simple and formless jelly. But simple, and formless as it appears to be, this jelly exhibits all the wonder and mystery of that power which we know as life. It is in virtue of that power that the dead or inorganic elements of which it is composed are held together in a special and delicate combination, which no other power can preserve in union, and which begins to dissolve the moment that power departs. And as in virtue of this power the constituent elements are held in a peculiar relation to each other, so in virtue of the same power does the combination possess peculiar relations with external things. It has the faculty of appropriating foreign substances into its own, making them subservient to the renewal of its own material, to the maintenance of its own energy, and to the preservation of its own separate individuality. It has the faculty, moreover, of giving off parts of itself, endowed with the same properties, to lead a separate existence. This same substance, which when analyzed has always the same chemical composition, and when alive has always the same fundamental properties, is at the root of every organism, whether animal or vegetable.—ARGYLL *Unity of Nature,* ch. 2, p. 29. (Burt.)

447. CELLS THE POPULATION OF THE VITAL KINGDOM—*Perfect Division of Labor—Definition and Size of Cell.*—What, then, is a cell? Imagine a speck of this living matter, averaging, say, the one-four-hundredth of an inch in diameter, of rounded shape, bounded by a kind of envelope, and having a particle (the nucleus) somewhere or other embedded in its interior, and you will have a fair conception of what a cell of ordinary size and form is likely to be. Some cells we know of—nerve-cells, indeed—average only the one-five-thousandth of an inch, or less, in diameter; and between big cells and little cells there are, of course, all gradations in size. These cells, then, are the workers of the body. They are the population of the vital kingdom. . . . There is perfect division of labor in the living state. One group of cells does not interfere with the work of another group. Each piece of labor, from the building of bone to the making of gastric juice, is carried out independently and thoroughly by workers set apart for the given purpose. The economy of a bee's hive is not more rigidly ordered than is the work of our own body in respect of its laborers and their specific duties.—ANDREW WILSON *Glimpses of Nature,* ch. 25, p. 81. (Hum., 1892.)

448. CERTAINTY AND CONJECTURE—*True Science Will Not Confuse.*—The burden, however, of this celebrated lecture [of Virchow] is a warning that a marked distinction ought to be made between that which is experimentally proved and that which is still in the region of speculation. . . . He insists that it [speculation] ought not to be put on the same evidential level as the former. "It ought," as he poetically expresses it, "to be written in small letters under the text." The audience ought to be warned that the speculative matter is only possible not actual truth—that it belongs to the region of "belief," and not to that of demonstration. As long as a problem continues in this speculative stage it would be mischievous, he considers, to teach it in our schools. "We ought not," he urges, "to represent our conjecture as a certainty, nor our hypothesis as a doctrine: this is inadmissible."—TYNDALL *Fragments of Science,* vol. ii, ch. 15, p. 397. (A., 1900.)

449. CERTAINTY OF INSTINCT—*Young Turtles and Crocodiles Readily Find Their Way to Unseen Water.*—Dr.

Davy, in his "Account of Ceylon," gives an interesting observation of his own on a young crocodile, which he cut out of the egg, and which, as soon as it escaped, started off in a direct line for a neighboring stream. Dr. Davy placed his stick before it to try to make the little animal deviate from its course; but it stoutly resisted the opposition, and raised itself into a posture of offense, just as an older animal would have done. Humboldt made exactly the same observation with regard to young turtles, and he remarks that, as the young normally quit the egg at night, they cannot see the water which they seek, and must therefore be guided to it by discerning the direction in which the air is most humid. He adds that experiments were made which consisted in putting the newly hatched animals into bags, carrying them to some distance from the shore, and liberating them with their tails turned towards the water. It was invariably found that the young animals immediately faced round and took without hesitation the shortest way to the water.—ROMANES *Animal Intelligence*, ch. 8, p. 257. (A., 1899.)

450. CERTAINTY, SCIENTIFIC, THE GROUND OF—*A Stable Consensus of Belief.*—It would thus appear that philosophy tends, after all, to unsettle what appear to be permanent convictions of the common mind and the presuppositions of science much less than is sometimes imagined. Our intuitions of external realities, our indestructible belief in the uniformity of Nature, in the nexus of cause and effect, and so on, are, by the admission of all philosophers, at least partially and relatively true; that is to say, true in relation to certain features of our common experience. At the worst, they can only be called illusory as slightly misrepresenting the exact results of this experience. And even so, the misrepresentation must, by the very nature of the case, be practically insignificant. And so in full view of the subtleties of philosophic speculation, the man of science may still feel justified in regarding his standard of truth, a stable consensus of belief, as above suspicion.—SULLY *Illusions*, ch. 12, p. 361. (A., 1897.)

451. CHALK CLIFFS OF ENGLAND WERE ONCE PART OF THE OCEAN FLOOR—However, the important points for us are, that the living *Globigerinæ* [see MICRO-ORGANISMS] are exclusively marine animals, the skeletons of which abound at the bottom of deep seas; and that there is not a shadow of reason for believing that the habits of the *Globigerinæ* of the chalk differed from those of the existing species. But if this be true, there is no escaping the conclusion that the chalk itself is the dried mud of an ancient deep sea.—HUXLEY *Lay Sermons*, ch. 9, p. 186. (G. P. P., 1899.)

452. CHANCE, A WORLD OF—*Cause and Effect Abolished—Reason Impossible.*—There used to be a children's book which bore the fascinating title of "The Chance World." It described a world in which everything happened by chance. The sun might rise or it might not; or it might appear at any hour, or the moon might come up instead. When children were born they might have one head or a dozen heads, and those heads might not be on their shoulders—there might be no shoulders—but arranged about the limbs. If one jumped up in the air it was impossible to predict whether he would ever come down again. That he came down yesterday was no guarantee that he would do it next time. For every day antecedent and consequent varied, and gravitation and everything else changed from hour to hour. To-day a child's body might be so light that it was impossible for it to descend from its chair to the floor; but to-morrow, in attempting the experiment again, the impetus might drive it through a three-story house and dash it to pieces somewhere near the center of the earth. In this chance world cause and effect were abolished. Law was annihilated. And the result to the inhabitants of such a world could only be that reason would be impossible. It would be a lunatic world with a population of lunatics.—DRUMMOND *Natural Law in the Spiritual World*, p. 33. (H. Al.)

453. CHANCE DOES NOT GIVE COHERENCE AND CONSISTENCY—*Earth's Progress Marked by Consistent Purpose.*—The tree is known by its fruits, and the fruits of chance are incoherence, incompleteness, unsteadiness, the stammering utterance of blind, unreasoning force. A coherence that binds all the geological ages in one chain, a stability of purpose that completes in the beings born to-day an intention expressed in the first creatures that swam in the Silurian ocean or crept upon its shores, a stedfastness of thought, practically recognized by man, if not acknowledged by him, whenever he traces the intelligent connection between the facts of Nature and combines them into what he is pleased to call his system of geology, or zoology, or botany—these things are not the fruits of chance or of an unreasoning force, but the legitimate results of intellectual power.—AGASSIZ *Geological Sketches*, ser. i, ch. 1, p. 21. (H. M. & Co., 1896.)

454. CHANCE FINALLY RULED OUT OF NATURE—*No "Fortuitous Concourse of Atoms"—Law Rules the Universe.*—The element of chance, which some atheists formerly admitted into their scheme of things, is expelled. Nobody would now waste his time in theorizing about a fortuitous concourse of atoms. We have so far spelled out the history of creation as to see that all has been done in strict accordance with law. The method has been the method of evolution, and the more we study it the more do we discern in it intelligible coherence. One

part of the story never gives the lie to another part.—FISKE *Through Nature to God*, pt. iii, ch. 2, p. 147. (H. M. & Co., 1900.)

455. CHANGE ALWAYS THE RESULT OF PREPARATION—*The Law of Continuity —Necessity of Belief in Causation.*—There is a common superstition that this so-called law [the law of continuity] shuts out the idea of creation and negatives the possibility, for example, of the sudden appearance of new forms of life. What it does negative, however, is not any appearance which is sudden, but only any appearance which has been unprepared. But these are two very different conceptions, altho they are conceptions very easily confounded. Innumerable things may come to be in a moment—in the twinkling of an eye. But nothing can come to be without a long, even if it be a secret, history. The "law of continuity" is, therefore, a phrase of ambiguous meaning; but at the bottom of it there lies the true and invincible conviction that for every change, however sudden—for every "leap," however wide—there has always been a long chain of predetermining causes, and that even the most tremendous bursts of energy and the most sudden exhibitions of force have all been slowly and silently prepared. In this sense the law of continuity is nothing but the idea of causation. It is founded on the necessary duration which we cannot but attribute to the existence of force, and this appears to be the only truth which the law of continuity represents.—ARGYLL *Unity of Nature*, ch. 4, p. 84. (Burt.)

456. CHANGE AMONG THE STARS—*Sirius Attended by a Darkened Sun.*—The knowledge of the law of gravitation has here also led to the discovery of new bodies, as in the case of Neptune. Peters of Altona found, confirming therein a conjecture of Bessel, that Sirius, the most brilliant of the fixed stars, moves in an elliptical path about an invisible center. This must have been due to an unseen companion, and when the excellent and powerful telescope of the University of Cambridge, in the United States, had been set up, this was discovered. It is not quite dark, but it light is so feeble that it can only be seen by the most perfect instruments. The mass of Sirius is found to be 13.76, and that of its satellite 6.71, times the mass of the sun; their mutual distance is equal to thirty-seven times the radius of the earth's orbit, and is therefore somewhat larger than the distance of Neptune from the sun. Another fixed star, Procyon, is in the same case as Sirius, but its satellite has not yet been discovered. You thus see that in gravitation we have discovered a property common to all matter, which is not confined to bodies in our system, but extends as far in the celestial space as our means of observation have hitherto been able to penetrate.—HELMHOLTZ *Popular Lectures*, lect. 4, p. 150. (L. G. & Co., 1898.)

457. CHANGE, CEASELESS, OF THE EARTH'S POSITION — *Its Path through Space an Infinite Spiral—We Never Twice Visit the Same Place.*—Owing to the existence of this motion [of the whole solar system toward a distant center], our globe has never passed twice through the same place, and it can never return to the spot where it is at present. We fall into the infinite, describing a series of spirals which are continually changing. Our abode is simply a moving globe carried through space, a veritable sport of cosmical forces, speeding through the eternal void towards an end of which we are ignorant, subject in its unsteady course to the most varied oscillations, balancing itself in the infinite with the lightness of an atom of dust in the sunlight, flying with a dizzy velocity above the unfathomable abyss, and carrying us for thousands of years past, and perhaps for thousands of years to come, to a mysterious destiny, which the most far-seeing mind cannot discern, beyond an horizon always fading into the future.—FLAMMARION *Popular Astronomy*, bk. i, ch. 1, p. 11. (A.)

458. CHANGE, GRADUAL, OF EARTH'S SURFACE—*Inroads of the Sea on British Coast.*—The waves constantly undermine the low chalk cliffs, covered with sand and clay, between Weybourne and Sherringham, a certain portion of them being annually removed. At the latter town I ascertained, in 1829, some facts which throw light on the rate at which the sea gains upon the land. It was computed, when the present inn was built, in 1805, that it would require seventy years for the sea to reach the spot, the mean loss of land being calculated, from previous observations, to be somewhat less than one yard annually. The distance between the house and the sea was fifty yards; but no allowance was made for the slope of the ground being from the sea, in consequence of which the waste was naturally accelerated every year, as the cliff grew lower, there being at each succeeding period less matter to remove when portions of equal area fell down. Between the years 1824 and 1829 no less than seventeen yards were swept away, and only a small garden was then left between the building and the sea. There was, in 1829, a depth of twenty feet (sufficient to float a frigate) at one point in the harbor of that port, where, only forty-eight years before, there stood a cliff fifty feet high, with houses upon it! If once in half a century an equal amount of change were produced suddenly by the momentary shock of an earthquake, history would be filled with records of such wonderful revolutions of the earth's surface; but, if the conversion of high land into deep sea be gradual, it excites only local attention.—LYELL *Principles of Geology*, ch. 19, p. 305. (A., 1854.)

459. CHANGE OF CHARACTER PRODUCED THROUGH CONTACT—*Alloys Made*

by Pressure.—In order to produce chemical changes in bodies, it is usually necessary that one at least be a liquid or be in a state of solution, and the combinations that occur lead to the production of bodies having quite different properties from either of their components. Similar results occur when metals are mixed together, forming alloys. Thus a mixture in certain proportions of lead, tin, bismuth, and cadmium produces an alloy which melts in boiling water, while the component metals only melt at double that temperature or more. Again, the strength of gold is doubled by the addition of one-five-hundredth part of the rare metal zirconium, indicating that the alloy must have a new arrangement of the molecules. But the interesting point is that alloys can be produced without melting the metals, for mere pressure often produces an alloy at the surfaces of contact; while in other cases, if fine filings of the component metals are thoroughly mixed together and then subjected to continued pressure, true alloys are produced.—WALLACE *The Wonderful Century,* ch. 7, p. 56. (D. M. & Co., 1899.)

460. CHANGE OF CLIMATE OF NORTH AMERICA—*Once the Home of Mastodon, Mammoth, and Camel.*—Of the remains of vertebrates, the bones of the mastodon or mammoth, and of the ox, camel, and horse, have been found in the sediments of Lake Lahontan, together with a single undetermined fish. The bones of a musk-ox were obtained near Salt Lake City under such conditions that it is believed they were buried in the upper strata of the Bonneville sediments. . . . The mastodon and mammoth roamed over nearly the whole of North America during Pleistocene times, but have since become extinct. The camel is no longer found on this continent, and the horse was extinct before the coming of the white man. The musk-ox is now found only far to the north. The extinction of some of these large animals, and the scattering of others to distant regions, suggests the lapse of a long period of time since they lived together where their remains are now found, and also points to great changes in climatic and other elements of their environment.—RUSSELL *Lakes of North America,* ch. 6, p. 114. (G. & Co., 1895.)

461. CHANGE OF COLOR AS THE EFFECT OF SIGHT—*The Chameleon—Flatfish—Variable Protective Coloring.*—[In some cases] the change [of color] is caused by reflex action set up by the animal seeing the color to be imitated, and the change produced can be altered or repeated as the animal changes its position. . . . The most striking example . . . is that of the chameleon, which changes to white, brown, yellowish, or green, according to the color of the object on which it rests. This change is brought about by means of two layers of pigment cells, deeply seated in the skin, and of bluish and yellowish colors. By suitable muscles these cells can be forced upwards so as to modify the color of the skin, which, when they are not brought into action, is a dirty white. These animals are excessively sluggish and defenseless, and the power of changing their color to that of their immediate surroundings is no doubt of great service to them. Many of the flatfish are also capable of changing their color according to the color of the bottom they rest on.—WALLACE *Darwinism,* ch. 8, p. 133. (Hum., 1889.)

462. CHANGE OF EYES TO SUIT ENVIRONMENT IN DEEP-SEA ORGANISMS—If the animals that now live in the depths of the sea are descended from the shallow-water forms of bygone epochs, they must have passed through many different habitats with diminished light until they reached their present dark abode in the abyss. In every new region they came to, the forms with larger and better eyes would be at an advantage in the fainter light, and would be more likely to survive and transmit their favorable variation in this respect to their offspring, than their less fortunate neighbors. Thus down to the depth of the limit of sunlight we should expect to find, as we do find in fishes, large-eyed species.—HICKSON *Fauna of the Deep Sea,* ch. 4, p. 74. (A., 1894.)

463. CHANGE OF FORMS FROM ANCIENT TO MODERN—*The Chambered Nautilus.*—The chambered nautilus is familiar to all, since, from the exquisite beauty of its shell, it is especially sought for by conchologists; but it is nevertheless not so common in our days as the squids and cuttlefishes, which are the most numerous modern representatives of the class. In the earliest geological days, on the contrary, those with a shell predominated, differing from the later ones, however, in having the shell perfectly straight instead of curved, tho its internal structure was the same as it is now and has ever been. Then, as now, the animal shut himself out from his last year's home, building his annual wall behind him, till his whole shell was divided into successive chambers, all of which were connected by a siphon. Some of the shells of this kind belonging to the Silurian deposits are enormous: giants of the sea they must have been in those days. They have been found fifteen feet long, and as large round as a man's body.—AGASSIZ *Geological Sketches,* ser. i, ch. 2, p. 49. (H. M. & Co., 1896.)

464. CHANGE OF HABITS IN A BIRD—*The Kea (Parrot) of New Zealand.*—The kea *(Nestor notabilis)* is a curious parrot inhabiting the mountain ranges of the Middle Island of New Zealand. It belongs to the family of brush-tongued parrots, and naturally feeds on the honey of flowers and the insects which frequent them, together with such fruits or berries as are found in

the region. Till quite recently this comprised its whole diet, but since the country it inhabits has become occupied by Europeans it has developed a taste for a carnivorous diet, with alarming results. It began by picking the sheepskins hung out to dry or the meat in process of being cured. About 1868 it was first observed to attack living sheep, which had frequently been found with raw and bleeding wounds on their backs. Since then it is stated that the bird actually burrows into the living sheep, eating its way down to the kidneys, which form its special delicacy. As a natural consequence, the bird is being destroyed as rapidly as possible. . . . The case affords a remarkable instance of how the climbing feet and powerful hooked beak developed for one set of purposes can be applied to another altogether different purpose, and it also shows how little real stability there may be in what appear to us the most fixed habits of life.—WALLACE *Darwinism,* ch. 3, p. 52. (Hum., 1889.)

465. CHANGE OF HEART—*Effect of Grief or Fear—New Mental Level Produces New Perspective.*—There is a form of decision [in which], in consequence of some outer experience or some inexplicable inward change, we suddenly pass from the easy and careless to the sober and strenuous mood, or possibly the other way. The whole scale of values of our motives and impulses then undergoes a change like that which a change of the observer's level produces on a view. The most sobering possible agents are objects of grief and fear. When one of these affects us, all "light fantastic" notions lose their motive power, all solemn ones find theirs multiplied manifold. The consequence is an instant abandonment of the more trivial projects with which we had been dallying, and an instant practical acceptance of the more grim and earnest alternative which till then could not extort our mind's consent. All those "changes of heart," "awakenings of conscience," etc., which make new men of so many of us, may be classed under this head. The character abruptly rises to another "level," and deliberation comes to an immediate end.—JAMES *Psychology,* vol. ii, ch. 26, p. 533. (H. H. & Co., 1899.)

466. CHANGE OF POSITIONS OF FIXED STARS—*Not One Star of Greek Astronomers Now Holds Its Place Unchanged—"Fixed Stars" a Misnomer.*—The heaven of the fixed stars, in contradiction to its very name, exhibits not only changes in the intensity of light, but also further variation from the perpetual motion of the individual stars. Allusion has already been made to the fact that, without disturbing the equilibrium of the star systems, no fixed point is to be found in the whole heavens, and that of all the bright stars observed by the earliest of the Greek astronomers, not one has kept its place unchanged. In the case of Arcturus, of *υ* Cassiopeiæ, and of a double star in Cygnus, this change of position has, by the accumulation of their annual proper motion during 2,000 years, amounted, respectively, to 2½, 3½, and 6 moon's diameters. In the course of 3,000 years about twenty fixed stars will have changed their places by 1° and upward. Since the proper motions of the fixed stars rise from $\frac{1}{20}$th of a second to 7.7 seconds (and consequently differ, at the least, in the ratio of 1.154), the relative distances also of the fixed stars from each other, and the configuration of the constellations themselves, cannot in long periods remain the same. The Southern Cross will not always shine in the heavens exactly in its present form, for the four stars of which it consists move with unequal velocity in different paths. How many thousand years will elapse before its total dissolution cannot be calculated. In the relations of space and the duration of time, no absolute idea can be attached to the terms great and small.—HUMBOLDT *Cosmos,* vol. iii, p. 182. (H., 1897.)

467. CHANGE OF SKIES IN SOUTHERN CLIMES—*Reversal of All Ideas of Position—The Sun North at Noon.*—If we travel southward we find that the north pole gradually sinks towards the horizon, while new stars come into view above the south horizon; consequently the circles of perpetual apparition and of perpetual disappearance both grow smaller. When we reach the earth's equator the south pole has risen to the south horizon, the north pole has sunk to the north horizon; the celestial equator passes from east to west directly overhead; and all the heavenly bodies in their diurnal revolutions describe circles of which one-half is above and the other half below the horizon. These circles are all vertical. South of the equator only the south pole is visible, the north one, which we see, being now below the horizon. Beyond the southern tropic the sun is north at noon, and, instead of moving from left to right, its course is from right to left.—NEWCOMB *Popular Astronomy,* ch. 1, p. 13. (H., 1899.)

468. CHANGE OF VIEW OF SCIENTIST—*Spencer Accepts Natural Selection.*—In the days when, not having been better instructed by Mr. Darwin, I believed that all changes of structure in organisms result from changes of function, I held that the cause of such changes of function is migration. . . . This conception was wrong in so far as it ascribed the production of new species entirely to inheritance of functionally wrought alterations (thus failing to recognize natural selection, which was not yet enunciated).—SPENCER *Biology,* pt. iii, ch. 14A, p. 568. (A., 1900.)

469. CHANGE, SILENT WITNESS OF—*Surface, Former, of Earth Removed—Granite from Depths Found at New Surface.*

—Granite [is] a rock believed to be of deep-seated origin. Its Plutonic character is evinced not less by its composition and structure than by its relation to the rock-masses that surround it. Every mass of granite, then, has cooled and consolidated, probably very slowly, and certainly at a less or greater depth in the earth's crust. When this rock is met with over a wide area at the actual surface, therefore—forming, it may be, great mountains or rolling and broken lowlands—we know that in such regions thick masses of formerly overlying rocks have been removed. The granite appears at the surface simply because the covering of rocks underneath which it cooled and solidified has been subsequently carried away.—GEIKIE *Earth Sculpture*, ch. 1, p. 16. (G. P. P., 1898.)

470. CHANGE THE CONDITION OF LIFE—*Repose of the Earth Will Be Its Death.* —As long as our planet yields less heat to space than she receives from the bodies of space, so long will the forms upon her surface undergo mutation, and as soon as equilibrium, in regard to heat, has been established we shall have, as Thomson has pointed out, not peace, but death. Life is the product and accompaniment of change, and the selfsame power that tears the flanks of the hills to pieces is the mainspring of the animal and vegetable worlds. Still there is something chilling in the contemplation of the irresistible and remorseless character of those infinitesimal forces, whose integration through the ages pulls down even the Matterhorn. Hacked and hurt by time, the aspect of the mountain from its higher crags saddened me. Hitherto the impression that it made was that of savage strength, but here we had inexorable decay.—TYNDALL *Hours of Exercise in the Alps*, ch. 24, p. 291. (A., 1898.)

471. CHANGE, UNCEASING, OF THE "SOLID EARTH"—*Continents Rising beneath Our Feet—"Thou Renewest the Face of the Earth" (Ps. civ, 30).*—It is certain that during the enormous periods of time of which the records have been discovered by the geologist there have always been continents and oceans upon the earth's surface, just as at present, and it is almost equally certain that the proportions of the earth's surface occupied by land and water, respectively, have not varied very widely from those which now prevail. But, at the same time, it is an equally well-established fact that the denuding forces ever at work upon the earth's surface would have been competent to the removal of existing continents many times over, in the vast periods covered by geological records. Hence we are driven to conclude that the subterranean movements have in past times entirely compensated for the waste produced by the denuding forces ever at work upon our globe. But this is not all. The subterranean forces not only produce upheaval; in a great many cases the evidences of subsidence are as clear and conclusive as are those of upheaval in others. Hence we are driven to conclude that the forces producing upheaval of portions of the earth's crust are sufficient, not only to balance those producing subsidence, but also to compensate for the destructive action of denuding agents upon the land-masses of the globe.—JUDD *Volcanoes*, ch. 10, p. 286. (A., 1899.)

472. CHANGE, UNSEEN, INVOLVES LIFE OR DEATH—*Fish Drowns in Airless Water.*—If a fish be placed in cooked water it swims for a while with its mouth at the surface, for just there is a film that is reacquiring its charge of oxygen, etc., by absorbing it from the air; but this film is so thin, and so poorly charged, that after a short struggle the fish dies for lack of oxygen in its blood; drowned as truly and completely as an air-breathing animal when immersed in any kind of water.—WILLIAMS *Chemistry of Cookery*, ch. 2, p. 10. (A., 1900.)

473. CHANGE WROUGHT BY NINETEENTH CENTURY—*Practical Application of Science—Slow Progress in Moral and Social Life.*—The close of the nineteenth century offers one of the most remarkable spectacles to the thoughtful observer. All educated people are agreed that it has in many respects immeasurably outstripped its predecessors, and has achieved tasks that were deemed impracticable at its commencement. An entirely new character has been given to the whole of our modern civilization, not only by our astounding theoretical progress in sound knowledge of Nature, but also by the remarkably fertile practical application of that knowledge in technical science, industry, commerce, and so forth. On the other hand, however, we have made little or no progress in moral and social life, in comparison with earlier centuries; at times there has been serious reaction. And from this obvious conflict there have arisen, not only an uneasy sense of dismemberment and falseness, but even the danger of grave catastrophes in the political and social world. It is, then, not merely the right, but the sacred duty, of every honorable and humanitarian thinker to devote himself conscientiously to the settlement of that conflict, and to warding off the dangers that it brings in its train.—HAECKEL *Riddle of the Universe*, ch. 1, p. 1. (H., 1900.)

474. CHANGES AMONG THE STARS—*Increase and Decrease of Brightness.*—In this long and careful series of observations it has been remarked that the stars are not fixed or unalterable, as they appear to be. There are some which since the time of Hipparchus have slowly diminished in brightness, and have even ended by becoming completely extinct. There are others whose light has gradually increased, and which are now much brighter than they were formerly.

Others, again, have changed in tint. . . . There are some, also, which have suddenly appeared, have shone with a dazzling brightness for several weeks or months, and have then relapsed into obscurity. In a large number a periodical variation of light has been established, in virtue of which certain stars, at first invisible to the naked eye, appear, increase progressively in brightness, then gradually diminish, and disappear, to again reappear after a certain number of days has elapsed; their periodicity is sometimes so exact that they are now calculated in advance.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 3, p. 580. (A.)

475. CHANGES IN SHAPE OF THE EARTH—*Alps Thrust Up from beneath the Sea—Folded and Contorted Strata.*—That [the Alps] were in whole or in part once beneath the sea will not be disputed; for they are in great part composed of sedimentary rocks which required a sea to form them. Their present elevation above the sea is due to one of those local changes in the shape of the earth which have been of frequent occurrence throughout geologic time, and which in some cases have depressed the land, and in others caused the sea-bottom to protrude beyond its surface. Considering the inelastic character of its materials, the protuberance of the Alps could hardly have been pushed out without dislocation and fracture; and this conclusion gains in probability when we consider the foldings, contortions, and even reversals in position of the strata in many parts of the Alps. Such changes in the position of beds which were once horizontal could not have been effected without dislocation.—TYNDALL *Hours of Exercise in the Alps*, ch. 20, p. 230. (A., 1898.)

476. CHANGES IN STRUCTURE OF THE EARTH—*Rapid Growth of Coral.*—It may be concluded, first, that considerable thicknesses of rock have certainly been formed within the present geological era by the growth of corals and the accumulation of their detritus; and, secondly, that the increase of individual corals and of reefs, both outwards or horizontally, and upwards or vertically, under conditions favorable to such increase, is not slow, when referred either to the standard of the average oscillations of level in the earth's crust, or to the more precise but less important one of a cycle of years.—DARWIN *Coral Reefs*, ch. 4, p. 107. (A., 1900.)

477. CHANGES IN THE BRAIN—*Present State a Combined Result of Circumstance and Sensibility.*—Whilst we think, our brain changes, and, like the aurora borealis, its whole internal equilibrium shifts with every pulse of change. The precise nature of the shifting at a given moment is a product of many factors. The accidental state of local nutrition or blood-supply may be among them. But just as one of them certainly is the influence of outward objects on the sense-organs during the moment, so is another certainly the very special susceptibility in which the organ has been left at that moment by all it has gone through in the past. Every brain-state is partly determined by the nature of this entire past succession. Alter the latter in any part, and the brain-state must be somewhat different. Each present brain-state is a record in which the eye of Omniscience might read all the foregone history of its owner.—JAMES *Psychology*, vol. i, ch. 9, p. 234. (H. H. & Co., 1899.)

478. CHANGES, MOLECULAR, IN PLANTS DUE TO LIGHT—*Colors of Flower Petals—Chlorophyl Produced by Sun.*—Light is an all-important agent of molecular changes in organic substances. . . . The characteristic matter called chlorophyl, which gives the green color to leaves, makes its appearance whenever the blanched shoots of plants are exposed to the sun; the petals of flowers, uncolored while in the bud, acquire their bright tints as they unfold; and on the outer surfaces of animals analogous changes are induced.—SPENCER *Biology*, pt. i, ch. 2, p. 35. (A., 1900.)

479. CHANGES OF A STAR — *Once Bright as Sirius, Now Almost Invisible.*—Changes such as these [the repeated increase and decline of light of a star in the ship Argo]—or even one of these changes—if occurring in the case of our own sun, would destroy life very quickly from the face of the earth, and probably from all the inhabited planets of the solar system. The mere change from the second magnitude to a brightness approaching that of Sirius implies an increase of emission of light and heat more than tenfold. But from this amazing access of splendor how wonderful has been the falling off by which the star has been rendered almost invisible. It is absolutely certain that this star, once doubtless a sun, and probably, like our own sun, the center of a scheme of circling worlds, gives out, day by day, far less than the hundredth part of the light and heat which it gave out daily only thirty years ago.—PROCTOR *Expanse of Heaven*, p. 197. (L. G. & Co., 1897.)

480. CHANGES, SUBTERRANEAN—*Defy Human Perception—Imagination Often at Fault—Prejudices Arising from Our Not Seeing Subterranean Changes.*—Nor is his [man's] position less unfavorable when, beholding a volcanic eruption, he tries to conceive what changes the column of lava has produced, in its passage upwards, on the intersected strata; or what form the melted matter may assume at great depths on cooling; or what may be the extent of the subterranean rivers and reservoirs of liquid matter far beneath the surface. It should therefore be remembered that the task imposed on those who study the earth's history requires no ordinary share of discretion; &c

we are precluded from collating the corresponding parts of the system of things as it exists now, and as it existed at former periods. If we were inhabitants of another element—if the great ocean were our domain, instead of the narrow limits of the land—our difficulties would be considerably lessened; while, on the other hand, there can be little doubt, altho the reader may perhaps smile at the bare suggestion of such an idea, that an amphibious being who should possess our faculties would still more easily arrive at sound theoretical opinions in geology, since he might behold, on the one hand, the decomposition of rocks in the atmosphere, or the transportation of matter by running water; and, on the other, examine the deposition of sediment in the sea, and the embedding of animal and vegetable remains in new strata. He might ascertain, by direct observation, the action of a mountain torrent, as well as of a marine current; might compare the products of volcanoes poured out upon the land with those ejected beneath the waters; and might mark, on the one hand, the growth of the forest, and, on the other, that of the coral reef. Yet, even with these advantages, he would be liable to fall into the greatest errors, when endeavoring to reason on rocks of subterranean origin. He would seek in vain, within the sphere of his observation, for any direct analogy to the process of their formation, and would therefore be in danger of attributing them, wherever they are upraised to view, to some "primeval state of Nature."—LYELL *Principles of Geology*, ch. 5, p. 69. (A., 1854.)

481. CHARACTER A SUM OF ACTIVITIES—*Every Action Counts—Hell a Present Fact in Evil Life.*—The hell to be endured hereafter, of which theology tells, is no worse than the hell we make for ourselves in this world by habitually fashioning our characters in the wrong way. Could the young but realize how soon they will become mere walking bundles of habits, they would give more heed to their conduct while in the plastic state. We are spinning our own fates, good or evil, and never to be undone. Every smallest stroke of virtue or of vice leaves its never so little scar. The drunken Rip Van Winkle, in Jefferson's play, excuses himself for every fresh dereliction by saying, "I won't count this time!" Well! he may not count it, and a kind Heaven may not count it; but it is being counted none the less. Down among his nerve-cells and fibers the molecules are counting it, registering and storing it up to be used against him when the next temptation comes. Nothing we ever do is, in strict scientific literalness, wiped out. Of course, this has its good side as well as its bad one. As we become permanent drunkards by so many separate drinks, so we become saints in the moral, and authorities and experts in the practical and scientific spheres, by so many separate acts and hours of work.—JAMES *Psychology*, vol. i, ch. 4, p. 127. (H. H. & Co., 1899.)

482. CHARACTER, FORMATION OF—*Development of the Will.*—Whilst, in its earlier stages, the educator aims to call forth and train the intellectual faculties of his pupil, and to form his moral character, by bringing appropriate external influences to bear upon him, every one who really understands his profession will make it his special object to foster the development, and to promote the right exercise, of that internal power, by the exertion of which each individual becomes the director of his own conduct, and so far the arbiter of his own destinies. This power is exercised by the will, in virtue of its domination over the automatic operations of the mind, as over the automatic movements of the body; the real self-formation of the ego commencing with his consciousness of the ability to determine his own course of thought and action. Until this self-directing power has been acquired, the character is the resultant of the individual's original constitution, and of the circumstances in which he may have been placed; and so long as the circumstances are unfavorable to its development, and to the operation of those higher tendencies which should furnish the best motives to its exercise, so long the character of the individual is formed for him rather than by him.—CARPENTER *Mental Physiology*, bk. i, ch. 1, sec. 8, p. 9. (A., 1900.)

483. CHEAPENING OF LABOR—*Women and Children Made Victims—Legislation Must Control Rapacity.*—"Thus," says Mr. Baker, one of the most experienced of our factory inspectors, "most of the workshops of this great commercial country are found to have fallen into the inevitable track of competitive industry, when unrestricted by law—namely, to cheapen prices by the employment of women and children, in the first instance, and then to increase production by protracted hours of work, without much regard to age, to sex, or to physical capability." This is the result of nature—of nature, at least, such as ours now is. But it is the result of that nature with all its nobler powers allowed to sleep. Power to control such evils has been given to man, and he is bound to use it. "Free labor, even in a free country," as Mr. Baker says, "requires the strong arm of the law to protect it from the cupidity and ignorance of parents." And by the "strong arm of the law" is meant nothing but the law of conscience and of reason asserting itself over the lower instincts of our nature. If under such conditions of society higher motives are ever to prevail, they must be supplied from without, and must be imposed in authoritative form through the legitimate organs of positive institution.—ARGYLL *Reign of Law*, ch. 7, p. 214. (Burt.)

484. CHECKS UPON INCREASE OF WEEDS — Seedlings, also, are destroyed in vast numbers by various enemies; for instance, on a piece of ground three feet long and two wide, dug and cleared, and where there could be no choking from other plants, I marked all the seedlings of our native weeds as they came up, and out of 357 no less than 295 were destroyed, chiefly by slugs and insects.—DARWIN *Origin of Species*, ch. 1, p. 63. (Burt.)

485. CHEMISTRY DEVELOPED BY ARABS—*Debt of Science to Moslem Investigators.*—The most powerful influence exercised by the Arabs on general natural physics was that directed to the advances of chemistry, a science for which this race created a new era. It must be admitted that alchemistic and new Platonic fancies were as much blended with chemistry as astrology with astronomy. The requirements of pharmacy, and the equally urgent demands of the technical arts, led to discoveries which were promoted, sometimes designedly, and sometimes by a happy accident depending upon alchemistic investigation into the study of metallurgy. The labors of Geber and the much more recent ones of Razes have been attended by the most important results. This period is characterized by the preparation of sulfuric and nitric acids, aqua regia, preparations of mercury, and of the oxids of other metals, and by the knowledge of the alcoholic process of fermentation. The first scientific foundation, and the subsequent advances of chemistry, are so much the more important, as they imparted a knowledge of the heterogeneous character of matter, and the nature of forces not made manifest by motion, but which now led to the recognition of the importance of composition, no less than to that of the perfectibility of form assumed in accordance with the doctrines of Pythagoras and Plato. Differences of form and of composition are, however, the elements of all our knowledge of matter—the abstractions which we believe capable, by means of measurement and analysis, of enabling us to comprehend the whole universe.—HUMBOLDT *Cosmos*, vol. ii, pt. ii p. 217. (H., 1897.)

486. CHEMISTRY, MODERN, ELEVATES WORK AND WORKER—*Intelligence in the Kitchen.*—Modern chemistry can throw into the kitchen a great deal of light that shall not merely help the cook in doing his or her work more efficiently, but shall also elevate both the work and the worker, and render the kitchen far more interesting, to all intelligent people who have an appetite for knowledge, as well as for food; more so than it can be while the cook is groping in rule-of-thumb darkness—is merely a technical operator unenlightened by technological intelligence.—WILLIAMS *Chemistry of Cookery*, ch. 1, p. 5. (A., 1900.)

487. CHILD A TUTOR FOR THE AFFECTIONS—*The Lengthening of School-days—Giving Affection Time to Grow.*—No greater day ever dawned for evolution than this on which the first human child was born. For there entered then into the world the one thing wanting to complete the ascent of man—a tutor for the affections. It may be that a mother teaches a child, but in a far deeper sense it is the child who teaches the mother. . . . To create motherhood and all that enshrines itself in that holy word required a human child. The creation of the mammalia established two schools in the world—the two oldest and surest and best equipped schools of ethics that have ever been in it—the one for the child, who must now at least know its mother; the other for the mother, who must as certainly attend to her child. The only thing that remains now is to secure that they shall both be kept in that school as long as it is possible to detain them. The next effort of evolution, therefore—the fifth process, as one might call it—is to lengthen out these school-days, and give affection time to grow. —DRUMMOND *Ascent of Man*, p. 281. (J. P., 1900.)

488. CHILD BELIEVES IN SPONTANEOUS GENERATION — *Childhood of the Race.*—The most copious source of this life without an ancestry was putrefying flesh; and, lacking the checks imposed by fuller investigation, the conclusion that flesh possesses and exerts this generative power is a natural one. I well remember, when a child of ten or twelve, seeing a joint of imperfectly salted beef cut into, and coils of maggots laid bare within the mass. Without a moment's hesitation I jumped to the conclusion that these maggots had been spontaneously generated in the meat. I had no knowledge which could qualify or oppose this conclusion, and for the time it was irresistible. The childhood of the individual typifies that of the race, and the belief here enunciated was that of the world for nearly two thousand years.—TYNDALL *Fragments of Science*, vol. ii, ch. 13, p. 291. (A., 1900.)

489. CHILD-TRAINING, NEED OF A SCIENCE OF — The principles of the mental culture of children especially can be outlined without trouble. We have a sufficiency of pedagogic models, almost in greater number than we have in dietetics or hygiene. And a young mother could look upon her babe with much more assurance if she were not obliged to acknowledge that this child of hers was to be an experiment—one on which, with more or less independence, and according to her own starts of fancy, she would make her experiments in training. For— let us not blind ourselves to the fact—our family training still remains upon the same low plane as political economy in the preceding century; it is purely natural economy. It should be the mission of our times to develop the science of bringing up children, and to put it into application, and to do away with this continual experimenting,

this training of children according to mere tradition.—VIRCHOW *Ueber die Erziehung des Weibes für seinen Beruf*, p. 27. (Translated for *Scientific Side-Lights.)*

490. CHOICE AMONG METHODS OF REACHING A SINGLE END—*A Superior Intelligence Can Predetermine Results, while Leaving Inferior Intelligence Free.*—Not infrequently the one thing willed, as the only end before the mind, may be accomplished in either one of several ways. Thus a skilled fencer who has willed to attack his opponent at what he knows to be his only weak point, and under the influence of this volition is watching his opportunity, may with incredible speed, and yet with conscious intelligent choice, select the particular form of giving his thrust—some new trick he has recently learned.—LADD *Psychology*, ch. 26, p. 630. (S., 1899.)

491. CHOICE THE GREAT WORK OF CONSCIOUSNESS — Consciousness is at all times primarily a selecting agency. Whether we take it in the lowest sphere of sense or in the highest of intellection, we find it always doing one thing, choosing one out of several of the materials so presented to its notice, emphasizing and accentuating that and suppressing as far as possible all the rest. The item emphasized is always in close connection with some interest felt by consciousness to be paramount at the time. —JAMES *Psychology*, vol. i, ch. 5, p. 139. (H. H. & Co., 1899.)

492. CHOICE THE RESULT OF A SERIES OF COMPARISONS—*Decision the Result of What One Brings to the Test.*—How is it when an alternative is presented to you for choice, and you are uncertain what you ought to do? You first hesitate, and then you deliberate. And in what does your deliberation consist? It consists in trying to apperceive the case successively by a number of different ideas, which seem to fit it more or less, until at last you hit on one which seems to fit it exactly. If that be an idea which is a customary forerunner of action in you, which enters into one of your maxims of positive behavior, your hesitation ceases, and you act immediately. If, on the other hand, it be an idea which carries inaction as its habitual result, if it ally itself with prohibition, then you unhesitatingly refrain. The problem is, you see, to find the right idea or conception for the case.—JAMES *Talks to Teachers*, ch. 15, p. 184. (H. H. & Co., 1900.)

493. CHRISTIANITY DEMANDS NO EXCEPTION TO LAW — *Christ's Work a Means to an End.*—Assuredly, whatever may be the difficulties of Christianity, this is not one of them—that it calls on us to believe in any exception to the universal prevalence and power of law. Its leading facts and doctrines are directly connected with this belief, and directly suggestive of it. The divine mission of Christ on earth—does not this imply not only the use of means to an end, but some inscrutable necessity that certain means, and these only, should be employed in resisting and overcoming evil? What else is the import of so many passages of Scripture implying that certain conditions were required to bring the Savior of man into a given relation with the race he was sent to save? "It behoved him . . . to make the captain of our salvation perfect through suffering." "It behoved him in all things to be made like unto his brethren, that he might be," etc.—with the reason added: "for in that he himself hath suffered being tempted, he is able to succour them that are tempted." Whatever more there may be in such passages, they all imply the universal reign of law in the moral and spiritual, as well as in the material world: that those laws had to be—behooved to be—obeyed; and that the results to be obtained are brought about by the adaptation of means to an end, or, as it were, by way of natural consequences from the instrumentality employed. This, however, is an idea which systematic theology generally regards with intense suspicion, tho, in fact, all theologies involve it, and build upon it.—ARGYLL *Reign of Law*, ch. 1, p. 31. (Burt.)

494. CHRISTIANITY LED TO STUDY OF NATURE—*Religion Ministers to Science.*—At the period when the feelings died away which had animated classical antiquity, and directed the minds of men to a visible manifestation of human activity rather than to a passive contemplation of the external world, a new spirit arose; Christianity gradually diffused itself, and, wherever it was adopted as the religion of the state, it not only exercised a beneficial influence on the condition of the lower classes by inculcating the social freedom of mankind, but also expanded the views of men in their communion with Nature. The eye no longer rested on the forms of Olympic gods. The Fathers of the Church, in their rhetorically correct and often poetically imaginative language, now taught that the Creator showed himself great in inanimate no less than in animate nature, and in the wild strife of the elements no less than in the still activity of organic development. . . . The ancient world is not abruptly separated from the modern, but modifications in the religious sentiments and the tenderest social feelings of men, and changes in the special habits of those who exercise an influence on the ideas of the mass, must give a sudden predominance to that which might previously have escaped attention. It was the tendency of the Christian mind to prove from the order of the universe and the beauty of Nature the greatness and goodness of the Creator. This tendency to glorify the Deity in his works gave rise to a taste for natural description. The earliest and most remarkable instances of this kind are to be met with in the writings of Minucius Felix, a rhetorician and lawyer at Rome, who lived in the beginning of the third century. . . .

We follow with pleasure the delineation of his twilight rambles on the shore near Ostia, which he describes as more picturesque and more conducive to health than we find it in the present day. In the religious discourse entitled "Octavius" we meet with a spirited defense of the new faith against the attacks of a heathen friend.—HUMBOLDT *Cosmos*, vol. ii, pt. i, p. 38. (H., 1897.)

495. CHRISTIANITY UNSHAKEN BY COPERNICAN ASTRONOMY—*Religion Has Outgrown the Ancient Cosmic Theories.*—It is instructive to observe that, while the Copernican astronomy has become firmly established in spite of priestly opposition, the foundations of Christian theology have not been shaken thereby. It is not that the question which once so sorely puzzled men has ever been settled, but that it has been outgrown. The speculative necessity for man's occupying the largest and most central spot in the universe is no longer felt. It is recognized as a primitive and childish notion. With our larger knowledge we see that these vast and fiery suns are after all but the Titan-like servants of the little planets which they bear with them in their flight through the abysses of space. . . . And as when God revealed himself to his ancient prophet he came, not in the earthquake or the tempest, but in a voice that was still and small, so that divine spark the soul, as it takes up its brief abode in this realm of fleeting phenomena, chooses not the central sun where elemental forces forever blaze and clash, but selects an outlying terrestrial nook where seeds may germinate in silence, and where through slow fruition the mysterious forms of organic life may come to take shape and thrive.—FISKE *Destiny of Man*, ch. 1, p. 16. (H. M. & Co., 1900.)

496. CHROMOSPHERE OF THE SUN—*Eclipses of 1842 and 1851—The Solar "Prominences."*—In July, 1842, a great eclipse occurred, and the shadow of the moon described a wide belt running across southern France, northern Italy, and a portion of Austria. The eclipse was carefully observed by many of the most noted astronomers of the world: and so completely had previous observations of the kind been forgotten, that the prominences, which appeared then with great brilliance, were regarded with extreme surprise, and became objects of warm discussion, not only as to their cause and location, but even as to their very existence. Some thought them mountains upon the sun, some that they were solar flames, and others, clouds floating in the sun's atmosphere. Others referred them to the moon, and yet others claimed that they were mere optical illusions. At the eclipse of 1851 (in Sweden and Norway), similar observations were repeated, and, as a result of the discussions and comparison of observations which followed, astronomers generally became satisfied that the prominences are real phenomena of the solar atmosphere, in many respects analogous to our terrestrial clouds; and several came more or less confidently to the conclusion, now known to be true, that the sun is entirely surrounded with a continuous stratum of the same substance.—YOUNG *The Sun*, ch. 6, p. 105. (A., 1898.)

497. CIRCULATION ON THE SUN—*Products Cooled on the Surface Poured Back for Reheating—Otherwise All on Earth Would Die—Spots That Seem to Dim the Glory Are the Very Source of Life.*—"Are the spots, these gigantic areas of disturbance, comparable to whirlpools or to volcanoes?" It may seen unphilosophical to assume that they are one or the other, and in fact they may possibly be neither; but it is certain that the surface of the sun would soon cool from its enormous temperature, if it were not supplied with fresh heat, and it is almost certain that this heat is drawn from the interior. As M. Faye has pointed out, there must be a circulation up and down, the cooled products being carried within, heated and brought out again, or the sun would, however hot, grow cold outside; and, what is of interest to us, the earth would grow cold also, and we should all die. No one, I believe, who has studied the subject, will contradict the statement that if the sun's surface were absolutely cut off from any heat-supply from the interior, organic life in general upon the earth (and our own life in particular) would cease much within a month. This solar circulation, then, is of nearly as much consequence to us as that of our own bodies, if we but knew it.—LANGLEY *New Astronomy*, ch. 1, p. 28. (H. M. & Co., 1896.)

498. CIVILIZATION A GAIN—*The Poor, as a Rule, Better Fed than Savages.*—To uncivilized men supplies of food come very irregularly. Long periods of scarcity are divided by short periods of abundance. And tho by gorging when opportunity occurs, something is done towards compensating for previous fasting, yet the effects of prolonged starvation cannot be neutralized by occasional enormous meals. Bearing in mind, too, that, improvident as they are, savages often bestir themselves only under pressure of hunger, we may fairly consider them as habitually ill-nourished—may see that even the poorer classes of civilized men, making regular meals on food separated from innutritive matters, easy to masticate and digest, tolerably good in quality, and adequate if not abundant in quantity, are much better nourished.—SPENCER *Biology*, pt. vi, ch. 12, p. 515. (A., 1900.)

499. CIVILIZATION, ANCIENT—*Encumbered by Relics of Barbarism—Evidences of Slow Advance—Hieroglyphics—Dog and Cat Worship.*—These, then [the Egyptians and Babylonians], are the two nations whose culture is earliest vouched for by inscriptions done at the very time of their ancient gran-

deur, and therefore it is safer to appeal to them than to other nations which can only show as proofs of their antiquity writings drawn up in far later ages. Looking at their ancient civilization, it seems to have been formed by men whose minds worked much like our own. No superhuman powers were required for the work, but just human nature groping on by roundabout ways, reaching great results, yet not half knowing how to profit by them when reached; solving the great problem of writing, yet not seeing how to simplify the clumsy hieroglyphics into letters; devoting earnest thought to religion and yet keeping up a dog and cat worship which was a jest even to the ancients; cultivating astronomy and yet remaining mazed in the follies of astrology. —TYLOR *Anthropology*, ch. 1, p. 22. (A., 1899.)

500. ——— ——— *Shows Traces of More Remote Antiquity—Prehistoric Development and Progress.*—In the midst of their [Egyptians and Babylonians] most striking efforts of civilization, the traces may be discerned of the barbaric condition which prevailed before; the Egyptian pyramids are burial-mounds like those of prehistoric England, but huge in size and built of hewn stone or brick; the Egyptian hieroglyphics, with their pictures of men and beasts and miscellaneous things, tell the story of their own invention, how they began as a mere picture-writing, like that of the rude hunters of America. Thus it appears that civilization, at the earliest dates where history brings it into view, had already reached a level which can only be accounted for by growth during a long prehistoric period. This result agrees with the conclusions already arrived at by the study of races and language.—TYLOR *Anthropology*, ch. 1, p. 22. (A., 1899.)

501. CIVILIZATION CAME TO EUROPE FROM WITHOUT—*Archeology Tells the Story—Fixing a Relative Date.*—When metals were very scarce, it would naturally sometimes happen that, in order to make up the necessary quantity, some tin would be added to copper, or vice versa. It would then be found that the properties of the alloy were quite different from those of either metal, and a very few experiments would determine the most advantageous proportion, which for axes and other cutting instruments is about nine parts of copper to one of tin. No implements or weapons of tin have yet been found, and those of copper are extremely rare, in western Europe, whence it has been inferred that the art of making bronze was known elsewhere before the use of either copper or tin was introduced into Europe.—AVEBURY *Prehistoric Times*, ch. 1, p. 4. (A., 1900.)

502. CIVILIZATION, CULTURE THE RIPE FRUIT OF—*Pioneer Too Hard Driven for Abstractions.*—**When the Pilgrim Fathers landed at Plymouth Rock, and when Penn made his treaty with the Indians, the newcomers had to build their houses, to chasten the earth into cultivation, and to take care of their souls. In such a community, science, in its more abstract forms, was not to be thought of. And at the present hour, when your hardy Western pioneers stand face to face with stubborn Nature, piercing the mountains and subduing the forest and the prairie, the pursuit of science, for its own sake, is not to be expected. The first need of man is food and shelter; but a vast portion of this continent is already raised far beyond this need. The gentlemen of New York, Brooklyn, Boston, Philadelphia, Baltimore, and Washington have already built their houses, and very beautiful they are; they have also secured their dinners, to the excellence of which I can also bear testimony. They have, in fact, reached that precise condition of well-being and independence when a culture, as high as humanity has yet reached, may be justly demanded at their hands. They have reached that maturity, as possessors of wealth and leisure, when the investigator of natural truth, for the truth's own sake, ought to find among them promoters and protectors.—TYNDALL *Lectures on Light*, p. 224. (A., 1898.)**

503. CIVILIZATION, DECLINE OF—*The Half-castes of India—The Digger Indians of North America.*—Degeneration is to be seen among the descendants of Portuguese in the East Indies, who have intermarried with the natives and fallen out of the march of civilization, so that newly arrived Europeans go to look at them lounging about their mean hovels in the midst of luxuriant tropical fruits and flowers, as if they had been set there to teach by example how man falls in culture where the need of effort is wanting. Another frequent cause of loss of civilization is when people once more prosperous are ruined or driven from their homes, like those Shoshone Indians who have taken refuge from their enemies, the Blackfeet, in the wilds of the Rocky Mountains, where they now roam, called Digger Indians, from the wild roots they dig for as part of their miserable subsistence. Not only the degraded state of such outcasts, but the loss of particular arts by other peoples, may often be explained by loss of culture under unfavorable conditions. —TYLOR *Anthropology*, ch. 1. p. 19. (A., 1899.)

504. ——— ——— *The South Sea Islanders Planting Nails—Lost Arts.*—The South Sea Islanders, tho not a very rude people when visited by Captain Cook, used only stone hatchets and knives, being indeed so ignorant of metal that they planted the first iron nails they got from the English sailors, in the hope of raising a new crop. Possibly their ancestors never had metals, but it seems as likely that these ancestors were an Asiatic people to whom metal was

known, but who, through emigration to ocean islands and separation from their kinsfolk, lost the use of it and fell back into the Stone Age. It is necessary for the student to be alive to the importance of decline in civilization.—TYLOR *Anthropology*, ch. 1, p. 19. (A., 1899.)

505. CIVILIZATION FAILS TO TEACH HUMANITY—*Extermination of Animals—Our Domestic Species Spared by Ancient Barbarians.*—It is sad to reflect that all our domestic animals have descended to us from those ancient times which we are accustomed to regard as dark or barbarous, while the effect of our modern so-called humane civilization has been purely destructive to animal life. Not one type do we rescue from the carnage going on at an ever-increasing rate over all the globe. To Australia and America, North and South, we look in vain for new domestic species, while even from Africa, with its numerous fine mammalian forms, and where England has been the conquering colonizing power for nearly a century, we take nothing. Even the sterling qualities of the elephant, the unique beauty of the zebra, appeal to us in vain. We are only teaching the tribes of that vast continent to exterminate a hundred noble species they would not tame. With grief and shame, even with dismay, we call to mind that our country is now a stupendous manufactory of destructive engines, which we are rapidly placing in the hands of all the savage and semi-savage peoples of the earth, thus insuring the speedy destruction of all the finest types in the animal kingdom.—HUDSON *Naturalist in La Plata*, ch. 17, p. 233. (C. & H., 1895.)

506. CIVILIZATION FOUNDED UPON HOME—*Influence of a Fixed Abode.*—What a simple fact and what a simple idea a house seems to be. To one it is a possession, to another wealth; to one nothing but property, to another only an investment. And yet with the house a new form was given to the entire world's history. There have been houseless peoples capable of making inroads into the world's history with elementary power, that have won great battles, overthrown empires and destroyed them. But they were not able to accomplish anything lasting until the wild riders and hunters from the forest and the wilderness built for themselves a hearth, or made themselves at home in what they had conquered. It was first with the home that the general civilization began, with the domestic life of the individual, the civilization of the individual. —STEIN *Die Frau auf dem Gebiete der Nationalökonomie. A Lecture.* (Translated for *Scientific Side-Lights.*)

507. CIVILIZATION IN NORTHERN LANDS—*Diversity and Interest of Northern Life—Abundance of Tropics Favors Indolence and Improvidence—Possible Future of Humanity under the Equator.*—During this last night on the Pará River a crowd of unusual thoughts occupied my mind. Recollections of English climate, scenery, and modes of life came to me with a vividness I had never before experienced during the eleven years of my absence. Pictures of startling clearness rose up of the gloomy winters, the long gray twilights, murky atmosphere, elongated shadows, chilly springs, and sloppy summers; of factory chimneys and crowds of grimy operatives, rung to work in early morning by factory bells; of union workhouses, confined rooms, artificial cares, and slavish conventionalities. To live again amid these dull scenes I was quitting a country of perpetual summer, where my life had been spent, like that of three-fourths of the people, in gipsy fashion, on the endless streams or in the boundless forests. I was leaving the equator, where the well-balanced forces of Nature maintained a land-surface and climate that seemed to be typical of mundane order and beauty, to sail toward the north pole, where lay my home under crepuscular skies somewhere about fifty-two degrees of latitude. It was natural to feel a little dismayed at the prospect of so great a change; but now, after three years of renewed experience of England, I find how incomparably superior is civilized life, where feelings, tastes, and intellect find abundant nourishment, to the spiritual sterility of half-savage existence, even tho it be passed in the Garden of Eden. What has struck me powerfully is the immeasurably greater diversity and interest of human character and social conditions in a single civilized nation than in equatorial South America, where three distinct races of men live together. The superiority of the bleak north to tropical regions, however, is only in their social aspect; for I hold to the opinion that, altho humanity can reach an advanced state of culture only by battling with the inclemencies of Nature in high latitudes, it is under the equator alone that the perfect race of the future will attain to complete fruition of man's beautiful heritage, the earth.—BATES *The Naturalist on the River Amazon*, ch. 13, p. 773. (Hum., 1880.)

508. CIVILIZATION, IN WHAT DOES IT CONSIST?—An extended knowledge of the useful arts, and the possession of such a settled system of law and government as enables men to live in great political communities, these are the essential features of what we understand by civilization.—ARGYLL *Unity of Nature*, ch. 10, p. 225. (Burt.)

509. CIVILIZATION NOT COMPLETED BY MATERIAL GOOD—*Spiritual Advance Its Goal—The Body the Vehicle for the Soul.*—If we can imagine a future time when warfare and crime shall have been done away with forever, when disease shall have been for the most part curbed, and when every human being by moderate labor can secure ample food and shelter, we can also see that in such a state of things the

work of civilization would be by no means completed. In ministering to human happiness in countless ways, through the pursuit of purely spiritual ends, in enriching and diversifying life to the utmost, there would still be almost limitless work to be done. I believe that such a time will come for weary and suffering mankind. Such a faith is inspiring. It sustains one in the work of life, when one would otherwise lose heart. But it is a faith that rests upon induction. The process of evolution is excessively slow, and its ends are achieved at the cost of enormous waste of life, but for innumerable ages its direction has been toward the goal here pointed out; and the case may be fitly summed up in the statement that whereas in its rude beginnings the psychical life was but an appendage to the body, in fully developed humanity the body is but the vehicle for the soul.—FISKE *Destiny of Man*, ch. 8, p. 64. (H. M. & Co., 1900.)

510. CIVILIZATION REMOVES OCCASIONS FOR FEAR — The progress from brute to man is characterized by nothing so much as by the decrease in frequency of proper occasions for fear. In civilized life, in particular, it has at last become possible for large numbers of people to pass from the cradle to the grave without ever having had a pang of genuine fear. Many of us need an attack of mental disease to teach us the meaning of the word. Hence the possibility of so much blindly optimistic philosophy and religion. The atrocities of life become "like a tale of little meaning, tho the words are strong"; we doubt if anything like us ever really was within the tiger's jaws, and conclude that the horrors we hear of are but a sort of painted tapestry for the chambers in which we lie so comfortably at peace with ourselves and with the world.—JAMES *Psychology*, vol. ii, ch. 24, p. 415. (H. H. & Co., 1899.)

511. CIVILIZATION TEACHES REGULAR WORK—*Savage Requires Excitement.*—We naturally assume that because barbarians are averse to regular labor their muscular action is less than our own. But this is not necessarily true. The monotonous toil is what they cannot tolerate; and they may be ready to go through as much or more exertion when it is joined with excitement. If we remember that the sportsman who gladly scrambles up and down rough hillsides all day after grouse or deer, would think himself hardly used had he to spend as much effort and time in digging; we shall see that a savage who is the reverse of industrious, may nevertheless be subject to a muscular waste not very different in amount from that undergone by the industrious.—SPENCER *Biology*, pt. vi, ch. 12, p. 515. (A., 1900.)

512. CIVILIZATION, THE DWELLING AN INDEX OF—In general, the dwelling provides an instrument for measuring the degree of civilization a people has attained. —ALSBERG *Die gesunde Wohnung*. (Translated for *Scientific Side-Lights.)*

513. CLASSIFICATION, BACTERIA ELUDE—Even yet, however, we are far from a scientific classification for bacteria. Nor is this matter for surprise. The development in this branch of biology has been so rapid that it has been impossible to assimilate the facts collected. The facts themselves by their remarkable variety have not aided classification. Names which a few years ago were applied to individual species are now representative, not of individuals, but of families and groups of species. Again, isolated characteristics of certain microbes, such as motility, power of liquefying gelatin, size, color, and so forth, which at first sight might appear as likely to form a basis for classification, are found to vary not only between similar germs, but in the same germ. Different physical conditions have so powerful an influence upon these microscopic cells that their individual characters are constantly undergoing change. For example, bacteria in old cultures assume a different size, and often a different shape, from younger members of precisely the same species. . . . Hence it will at once appear to the student of bacteriology that, tho there is great need for classification amongst the six or seven hundred species of microbes, our present knowledge of their life-history is not yet advanced enough to form more than a provisional arrangement.—NEWMAN *Bacteria*, ch. 1, p. 7. (G. P. P., 1899.)

514. CLASSIFICATION DEPENDENT UPON PURPOSE — It is always easy to find fault with a classification. There are a hundred possible ways of arranging any set of objects, and something may almost always be said against the best and in favor of the worst of them. But the merits of a classification depend on the purposes to which it is instrumental.—MILL *Positive Philosophy of Auguste Comte*, p. 40. (H. H. & Co., 1887.)

515. CLEANLINESS SECURES PURITY OF MILK—*Gross Pollution under Ordinary Conditions.*—Professor Russell [in "Dairy Bacteriology," p. 46] recounts a simple experiment [as follows]:

"A cow that had been pastured in a meadow was taken for the experiment, and the milking done out-of-doors, to eliminate as much as possible the influence of germs in the barn air. Without any special precaution being taken the cow was partially milked, and during the operation a covered glass dish, containing a thin layer of sterile gelatin, was exposed for sixty seconds underneath the belly of the cow in close proximity to the milk-pail. The udder, flank, and legs of the cow were then thoroughly cleaned with water, and all of the precautions referred to before were carried out, and the milking then resumed. A second

plate was then exposed in the same place for an equal length of time, a control also being exposed at the same time at a distance of ten feet from the animal and six feet from the ground to ascertain the germ contents of the surrounding air. From this experiment the following instructive data were gathered. Where the animal was milked without any special precautions being taken there were 3,250 bacterial germs per minute deposited on an area equal to the exposed top of a ten-inch milk-pail. Where the cow received the precautionary treatment as suggested above, there were only 115 germs per minute deposited on the same area. In the plate that was exposed to the surrounding air at some distance from the cow there were 65 bacteria. This indicates that a large number of organisms from the dry coat of the animal can be kept out of milk if such simple precautions as these are carried out."—NEWMAN *Bacteria*, ch. 6, p. 182. (G. P. P., 1899.)

516. CLEANLINESS, UTILITY OF, DISCOVERED WHILE REASONS WERE UNKNOWN—To the credit of English surgeons it stands recorded that, guided by their practical sagacity, they had adopted in their hospitals measures of amelioration which reduced, almost to a minimum, the rate of mortality arising from the "mortification" of wounds. They had discovered the evils incident to "dirt"; and, by keeping dirt far away from them, they had saved innumerable lives, which would undoubtedly have succumbed under conditions prevalent in many of the hospitals of continental Europe. In thus acting, English surgeons were, for the most part, "wiser than they knew." Their knowledge, however momentous in its practical applications, was still empirical knowledge. That dirt was fatal they had discovered; but why it was fatal few of them knew.—TYNDALL *Floating Matter of the Air*, int., p. 7. (A., 1895.)

517. CLEANLINESS, UTILITY OF, SCIENTIFICALLY DEMONSTRATED—*Lister and Schwann Proved Germs to Be Deadly.*—At this point Lister came forward with a scientific principle which rendered all plain. Dirt was fatal, not as dirt, but because it contained living germs which, as Schwann was the first to prove, are the cause of putrefaction. Lister extended the generalization of Schwann from dead matter to living matter, and by this apparently simple step revolutionized the art of surgery. He changed it, in fact, from an art into a science.—TYNDALL *Floating Matter of the Air*, int., p. 8. (A., 1895.)

518. CLEARNESS OF THE CELESTIAL ETHER—*Contrast with the Atmosphere of Earth.*—It is marvelous that we can perceive the stars at such a distance. What an admirable transparency in these immense spaces to permit the light to pass, without being wasted, to thousands of billions of miles! Around us, in the thick air which envelops us, the mountains are already darkened and difficult to see at seventy miles; the least fog hides from us objects on the horizon. What must be the tenuity, the rarefaction, the extreme transparency of the ethereal medium which fills the celestial spaces!—FLAMMARION *Popular Astronomy*, bk. vi, ch. 1, p. 553. (A.)

519. CLIMATE, ALTERNATIONS OF—*Change from Glacial Epoch to Tropical Period—Siberian Mammoths — Elephant, Lion, Tiger.*—It will naturally be asked whether some recent geological discoveries bringing evidence to light of a colder, or as it has been termed "glacial epoch," towards the close of the Tertiary period throughout the northern hemisphere, does not conflict with the theory, above alluded to, of a warmer temperature having prevailed in the eras of the Eocene, Miocene, and Pliocene formations. In answer to this inquiry, it may certainly be affirmed that an oscillation of climate has occurred in times immediately antecedent to the peopling of the earth by man; but proof of the intercalation of a less genial climate, at an era when nearly all the marine and terrestrial testacea had already become specifically the same as those now living, by no means rebuts the conclusion previously drawn, in favor of a warmer condition of the globe during the ages which elapsed while the tertiary strata were deposited. In some of the most superficial patches of sand, gravel, and loam, scattered very generally over Europe, and containing recent shells, the remains of extinct species of land quadrupeds have been found, especially in places where the alluvial matter appears to have been washed into small lakes, or into depressions in the plains bordering ancient rivers. Similar deposits have also been lodged in rents and caverns of rocks, where they may have been swept in by land floods, or introduced by engulfed rivers during changes in the physical geography of these countries. . . . Among the extinct mammalia thus entombed, we find species of the elephant, rhinoceros, hippopotamus, bear, hyena, lion, tiger, monkey (*Macacus*), and many others, consisting partly of genera now confined to warmer regions.—LYELL *Principles of Geology*, ch. 6, p. 75. (A., 1854.)

520. ——— ——— *Elephants Once Abundant in Siberia—Ivory in Northern Russia.*—The most recent discoveries made in 1843 by Mr. Middendorf, a distinguished Russian naturalist, and which he communicated to me in September, 1846, afford more precise information as to the climate of the Siberian lowlands, at the period when the extinct quadrupeds were entombed. One elephant was found on the Tas, between the Obi and Yenisei, near the arctic circle, about lat. 66° 30′ N., with some parts of the flesh in so perfect a state that the bulb of the eye is now preserved in the mu-

seum at Moscow. Another carcass, together with a young individual of the same species, was met with in the same year, 1843, in lat. 75° 15′ N., near the River Taimyr, with the flesh decayed. It was embedded in strata of clay and sand, with erratic blocks, at about 15 feet above the level of the sea. In the same deposit Mr. Middendorf observed the trunk of a larch tree *(Pinus larix)*, the same wood as that now carried down in abundance by the Taimyr to the Arctic Sea. There were also associated fossil shells of living northern species, and which are moreover characteristic of the drift or glacial deposits of Europe. Among these *Nucula pygmæa*, *Tellina calcarea*, *Mya truncata*, and *Saxicava rugosa* were conspicuous.

So fresh is the ivory throughout northern Russia that, according to Tilesius, thousands of fossil tusks have been collected and used in turning; yet others are still procured and sold in great plenty. He declares his belief that the bones still left in northern Russia must greatly exceed in number all the elephants now living on the globe.—LYELL *Principles of Geology*, ch. 6, p. 81. (A., 1854.)

521. CLIMATE, EFFECT OF, ON STRUGGLE FOR LIFE—The action of climate seems at first sight to be quite independent of the struggle for existence; but in so far as climate chiefly acts in reducing food, it brings on the most severe struggle between the individuals, whether of the same or of distinct species, which subsist on the same kind of food. Even when climate, for instance, extreme cold, acts directly, it will be the least vigorous individuals, or those which have got least food through the advancing winter, which will suffer the most.—DARWIN *Origin of Species*, ch. 1, p. 64. (Burt.)

522. CLIMATE, EFFECT OF, UPON MAN—In the climate of America, compared with that of England, there is an important difference. That of England is a moist, moderate island climate, while that of America is continental, with extremely dry west winds and great extremes of heat and cold in summer and winter. The elimination of heat is greater in America, and consequently greater production of warmth within the organism is necessary; the tissue change has to be more rapid. This is apparent in the entire being of the American. Désor describes him exactly when he says that the American's activity, his hurry, his rushing, is more a matter of instinct, more the result of natural impatience than of necessity, the cause that creates restlessness and haste in the Englishman. The latter runs from zeal for business, the American from an inner impulse.—OPPENHEIMER *Ueber den Einfluss des Klimas auf den Menschen*, p. 31. (Translated for *Scientific Side-Lights.*)

523. CLIMATE EFFECTS CHANGES OF CHARACTERISTICS—*Wool Replaced by Hair—Hairless Cattle—Whiteness of Arctic Animals.*—I have myself seen in Southdown sheep, which had been transported only two years previously to the West Indies, the thick covering of wool replaced by short crisp hair, scarcely distinguishable from that of the goats which had inhabited the island for several generations; and the hottest parts of the South American pampas are inhabited by breeds of cattle (the descendants of those introduced by the Spaniards), of which some are nearly, and others quite, destitute of hair, and which cannot live in the more temperate air of the slopes of the Andes. It seems clear, then, that this adaptation results from some direct physical action of temperature on the constitution of the animals; and yet (like the expansion of water in cooling from 39.2° to 32°) it is in direct opposition to a very general law. The same may be said of the winter whitening of the fur and plumage of arctic mammals and birds. For, altho this (like the preceding) has been adduced as an example of "natural selection"—the white varieties surviving because they escape being seen upon ground whitened by snow—yet there must have been some cause for the production of the white varieties.—CARPENTER *Nature and Man*, lect. 15, p. 441. (A., 1889.)

524. CLOTHING OF BARK AND LEAVES—*Reversion to Primitive Customs.*—To come now to clothing proper. The man who wants a garment gets it in the simplest way when he takes the covering off a tree or a beast, and puts it on himself. The bark of trees provides clothes for rude races in many districts, as for instance in the curious use which natives of the Brazilian forests have long made of the so-called "shirt-tree" *(Lecythis)*. A man cuts a four- or five-feet length of the trunk, or a large branch, and gets the bark off in an entire tube, which he has then only to soak and beat soft and to cut slits for armholes, to be able to slip it on as a ready-made shirt; or a short length will make a woman's skirt. The wearing of bark has sometimes been kept up as a sign of primitive simplicity. Thus in India it is written in the laws of Manu that when the gray-haired Brahman retires into the forest to end his days in religious meditation, he shall wear a skin or a garment of bark. A ruder people, the Kayans of Borneo, while in common life they like the smart foreign stuffs of the trader, when they go into mourning throw them off and return to the rude native garment of bark-cloth. In Polynesia the manufacture of tapa from the bark of the paper-mulberry was carried to great perfection, the women beating it out with grooved clubs into a sort of vegetable felt, and ornamenting it with colored patterns stamped on. The people were delighted with the white paper of the Europeans, and dressed themselves in it as a fine

variety of tapa, till they found that the first shower of rain spoiled it. Leaves, also, are made into aprons or skirts which clothe various rude tribes. Not only are there "leaf-wearers" in India, but at a yearly festival in Madras the whole low-caste population cast off their ordinary clothing and put on aprons of leafy twigs.—TYLOR *Anthropology*, ch. 10, p. 244. (A., 1899.)

525. CLOUD-CAPITALS OF VIEWLESS COLUMNS—*Cumulous Clouds.*—Similar remarks apply to the formation of cumuli in our own latitudes; they are the heads of vaporous columns which rise from the earth's surface, and are precipitated as soon as they reach a certain elevation. Thus, the visible cloud forms the capital of an invisible pillar of saturated air. The top of such a column, raised above the lower vapor-screen which clasps the earth, and offering itself to space, is chilled by radiation and precipitated as cloud. Mountains act as condensers, partly by the coldness of their own masses, which they owe to their elevation. Above them spreads no vapor-screen of sufficient density to intercept their heat, which consequently passes unrequited into space. When the sun is withdrawn, this loss is shown by the quick descent of the thermometer.—TYNDALL *Heat a Mode of Motion*, lect. 13, p. 384. (A., 1900.)

526. CLOUD, INCIPIENT—*Rivals Azure of Italian Sky.*—It is possible, by duly regulating the quantity of vapor, to make our precipitated particles grow from an infinitesimal, and altogether ultra-microscopic size, to specks of sensible magnitude; and by means of these particles, in a certain stage of their growth, we can produce a blue which shall rival, if it does not transcend, that of the deepest and purest Italian sky. Let this point be in the first place established. Associated with our experimental tube is a barometer, the mercurial column of which now indicates that the tube is exhausted. Into the tube I introduce a quantity of the mixed air and nitrite of butyl vapor, sufficient to depress the mercurial column one-twentieth of an inch; that is to say, the air and vapor together exert a pressure of one-six-hundredth of an atmosphere. I now add a quantity of air and hydrochloric acid, sufficient to depress the mercury half an inch further, and into this compound and highly attenuated atmosphere I discharge the beam of the electric light. The effect is slow; but gradually within the tube arises a splendid azure, which strengthens for a time, reaches a maximum of depth and purity, and then, as the particles grow larger, passes into whitish blue. This experiment is representative, and it illustrates a general principle. Other colorless substances of the most diverse properties, optical and chemical, might be employed for this experiment. The incipient cloud, in every case, would exhibit this superb blue; thus proving to demonstration that particles of infinitesimal size, without any color of their own, and irrespective of the optical properties exhibited by the substances in a massive state, are competent to produce the color of the sky.—TYNDALL *Heat a Mode of Motion*, lect. 16, p. 484. (A., 1900.)

527. CLOUDS WITH LINING OF BLUE AND GOLD—*Beauty of Sunrise and Sunset on Worlds Lit by Colored Suns.*—The skies, however, must be often exceedingly beautiful. Our clouds have their silver lining, because it is the white light of the sun which illumines them. Our summer sky presents glowing white clouds to our view, and at other times we see the various shades between perfect whiteness and an almost black hue, corresponding to the various degrees in which the illuminated side of a cloud is turned towards us. But imagine how beautiful the scene must be, when those parts of a cloud which would otherwise appear simply darker, shine with a fuller blue light or (as the case may be) with a fuller orange light. How gorgeous again must be the coloring of the clouds which fleck the sky when one or other sun is setting! At such times on our earth we see the most beautiful tints, owing to the various degrees in which the atmosphere affects the light of our single sun; but how wonderful must be the varieties of color when, in addition to this cause of varying tints, there is a sun of complementary color illuminating those parts of each cloud which would be simply dark were there no other sun but the orb which is actually setting!—PROCTOR *Expanse of Heaven*, pp. 235-236. (L. G. & Co., 1897.)

528. COAL-DEPOSITS PROVE MILDER CLIMATE—*Tree-ferns Now Only Tropical.*—But it is from the more ancient coal-deposits that the most extraordinary evidence has been supplied in proof of the former existence of a very different climate—a climate which seems to have been moist, warm, and extremely uniform—in those very latitudes which are now the colder, and, in regard to temperature, the most variable, regions of the globe. We learn from the researches of Adolphe Brongniart, Goeppert, and other botanists, that in the flora of the Carboniferous era there was a great predominance of ferns, some of which were arborescent. . . . This prevalence of ferns indicates a moist, equable, and temperate climate, and the absence of any severe cold, for such are the conditions which, at the present day, are found to be most favorable to that tribe of plants. It is only in the islands of the tropical oceans, and of the southern temperate zone, such as Norfolk Island, Otaheite, the Sandwich Islands, Tristan d'Acunha, and New Zealand, that we find any near approach to that remarkable preponderance of ferns which is characteristic of the Carboniferous flora. It has been observed that tree-ferns and other forms of vegetation which flourished most luxuriantly within the tropics extend to a much

greater distance from the equator in the southern hemisphere than in the northern, being found even as far as 46° S. latitude in New Zealand. There is little doubt that this is owing to the more uniform and moist climate occasioned by the greater proportional area of sea.—LYELL *Principles of Geology*, ch. 6, p. 87. (A., 1854.)

529. CODE OF HONOR—*Permissions of Moral Evil.*—What may be called "club opinion" is one of the very strongest forces in life. The thief must not steal from other thieves; the gambler must pay his gambling debts, tho he pay no other debts in the world. The code of honor of fashionable society has throughout history been full of permissions as well as of vetoes, the only reason for following either of which is that so we best serve one of our social selves. You must not lie in general, but you may lie as much as you please if asked about your relations with a lady; you must accept a challenge from an equal, but if challenged by an inferior you may laugh him to scorn: these are examples of what is meant. —JAMES *Psychology*, vol. i, ch. 10, p. 295. (H. H. & Co., 1899.)

530. COINCIDENCE OF GREAT DISCOVERIES—*Columbus and Copernicus.*—The age of Columbus, Gama, and Magellan—the age of great maritime enterprises—coincided in a most wonderful manner with many great events, with the awakening of a feeling of religious freedom, with the development of nobler sentiments for art, and with the diffusion of the Copernican views regarding the system of the universe. Nicolaus Copernicus had already attained his twenty-first year, and was engaged in making observations with the astronomer Albert Brudzewski, at Cracow, when Columbus discovered America. Hardly a year after the death of the great discoverer, and after a six years' residence at Padua, Bologna, and Rome, we find him returned to Cracow, and busily engaged in bringing about a thorough revolution in the astronomical views of the universe. . . . He was nominated, in 1510, canon of Frauenburg, where he labored for thirty-three years on the completion of his work, entitled "De Revolutionibus Orbium Cœlestium." The first printed copy was brought to him when, shattered in mind and body, he was preparing himself for death. He saw it and touched it, but his thoughts were no longer fixed on earthly things, and he died several days afterward (on the 24th of May, 1543).—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 303. (H., 1897.)

531. ——— ——— *Moons of Jupiter Simultaneously Discovered.*—The moons of Jupiter, the first of all the secondary planets discovered by the telescope, were first seen, almost simultaneously and wholly independently, on the 29th of December, 1609, by Simon Marius at Ansbach, and on the 7th of January, 1610, by Galileo at Padua. In the publication of this discovery, Galileo, by the "Nuncius Siderius" (1610), preceded the "Mundus Jovialis" (1614) of Simon Marius. . . .

The discovery of Jupiter's satellites marks an ever memorable epoch in the history and the vicissitudes of astronomy. The occultations of the satellites, or their entrance into Jupiter's shadow, led to a knowledge of the velocity of light (1675), and, through this knowledge, to the explanation of the *aberration-ellipse* of the fixed stars (1727), in which the great orbit of the earth, in its annual course round the sun, is, as it were, reflected on the vault of heaven. These discoveries of Römer and Bradley have been justly termed "the keystone of the Copernican system," the perceptible evidence of the translatory motion of the earth.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, pp. 320, 322. (H., 1897.)

532. COLOR, ABSENCE OF, HELPFUL AT A CERTAIN STAGE—*Advantages of the Glass Animals in the Struggle for Existence.*—Evidently for all glass animals, carrying on their unceasing warfare, their waterlike bodily composition is of the greatest utility. The pursuers can approach their prey without being observed, the pursued are able more easily to escape than if both were colored and wanting in transparency, and therefore more readily visible in clear water. Suppose we assume that of these glass animals different varieties existed originally, varying especially in the degree of transparency and want of color. Then, certainly, those individuals that were most transparent and colorless would achieve the preponderance in the struggle for existence, at the same time confirming and strengthening those advantageous individual peculiarities for generations, and finally arrive at a perfectly glasslike development.—HAECKEL *Generelle Morphologie*, vol. ii, p. 243. (Translated for *Scientific Side-Lights.*)

533. COLOR A NEGATIVE QUALITY—*Produced by Subtraction, Not by Addition.*—Pass a black ribbon through the colors of the spectrum; it quenches all of them. The meaning of blackness is thus revealed—it is the result of the absorption of all the constituents of solar light. Pass a red ribbon through the spectrum. In the red light the ribbon is a vivid red. Why? Because the light that enters the ribbon is not quenched or absorbed, but in great part sent back to the eye. Place the same ribbon in the green of the spectrum; it is black as jet. It absorbs the green light, and leaves the space on which it falls a space of intense darkness. Place a green ribbon in the green of the spectrum. It shines vividly with its proper color; transfer it to the red, it is black as jet. Here it absorbs all the light that falls upon it, and offers mere darkness to the eye. Thus, when white light is employed, the red sifts it by quenching the

green, and the green sifts it by quenching the red, both exhibiting the residual color. The process through which natural bodies acquire their colors is therefore a negative one. The colors are produced by subtraction, not by addition. This red glass is red because it destroys all the more refrangible rays of the spectrum. This blue liquid is blue because it destroys all the less refrangible rays. Both together are opaque because the light transmitted by the one is quenched by the other. In this way, by the union of two transparent substances we obtain a combination as dark as pitch to solar light. This other liquid, finally, is purple because it destroys the green and the yellow, and allows the terminal colors of the spectrum to pass unimpeded. From the blending of the blue and the red this gorgeous purple is produced.—TYNDALL *Lectures on Light*, lect. 1, p. 32. (A., 1898.)

534. COLOR A PROTECTION—*Bird Feeding on Ground—Tree-trunk a Hiding-place.*—The Sclerurus, altho an inhabitant of the darkest forest, and provided with sharply curved claws, never seeks its food on trees, but exclusively on the ground, among the decaying fallen leaves; but, strangely enough, when alarmed it flies to the trunk of the nearest tree, to which it clings in a vertical position, and, remaining silent and motionless, escapes observation by means of its dark protective color.—HUDSON *Naturalist in La Plata*, ch. 18, p. 240. (C. & H., 1895.)

535. COLOR AS PROTECTIVE FROM HEAT—*White for Military Uniforms.*—By instinct, or perhaps as the result of the experience of centuries, the native Algerians have adopted white as the color for their clothing. Evidently they never dream of manufacturing uniforms of colored woolen cloth. It would be possible to shade soldiers on a march, or other expedition, from the sun's rays, with the aid of a simple cotton burnoose at only a slightly increased cost, and whose volume would be very little. This is an experiment worth trying, at least on a small scale; the use of this vestment would have as an immediate result the placing of the soldier within a medium cooler by ten or a dozen degrees, and all physicians who have accompanied troops on a march are aware that a number of degrees more or less for a man that is fatigued, or has an attack of fever, or is wounded, is a question of life or death. In any case, it would always be well to place some of these white vestures at the disposal of the physician for the use of sick men menaced or attacked by congestion during a march.—COULIER *Expériences sur les Étoffes qui servent à confectionner les Vêtements Militaires*, p. 138, *Journal de la Physiologie de l'Homme et des Animaux.* (Translated for *Scientific Side-Lights.*)

536. COLOR, DEPENDENCE OF, ON OBSERVER—*Color-blindness—The World in Chiaroscuro.*—It is agreed alike by physicists and physiologists that color does not exist as such in the object itself, which has merely the power of reflecting or transmitting a certain number of millions of undulations in a second, and these only produce that affection of our consciousness which we call color, when they fall upon the retina of the living percipient. And if there be that defect either in the retina or in the apparatus behind it, which we call "color-blindness" or Daltonism, some particular hues cannot be distinguished, or there may even be no power of distinguishing any color whatever. If we were all like Dalton, we should see no difference, except in form, between ripe cherries hanging on a tree and the green leaves around them; if we were all affected with the severest form of color-blindness, the fair face of Nature would be seen by us as in the chiaroscuro of an engraving of one of Turner's landscapes, not as in the glowing hues of the wondrous picture itself.—CARPENTER *Nature and Man*, p. 201. (A., 1889.)

537. COLOR IN FLOWERS AND FRUITS—*Beauty Subserves a Purpose.*—Between fruits and flowers, in the matter of color, there is a close and intimate association. Every schoolboy who is taught botany knows that flowers are colored to attract insects, while the insects in turn cross-fertilize the plants by carrying the pollen-dust from one flower to another flower of the same species. Color in flowers, then, has a purpose all undreamt of by the older botanists. What of fruits? Color here, in the logical sequence of events, must be credited with a purpose also. Let us see what that design may be. When you look at an apple or orange you are struck by the apparently big size of the edible part of the fruit, and by the relatively small size of the seeds. Compared with, say, the fruits of a buttercup, represented by the collection of little dry green bodies borne on the end of the flower-stalk, the apple, orange, peach, plum, and cherry are grandiose in the extreme. The apple-substance does not nourish the seed. There is no question of nutrition involved in the matter at all. The seeds are all ready to produce the new plants, and lie concealed within the apple, and cherry or plum stone, waiting their season and opportunity. Why, then, all this big growth of eatable material? The answer is, "For the birds and insects, and for any other animal agencies which will help the plant on its way of life." The blackbirds that peck at the peaches and apples are Nature's servitors. They come for their food to the gardener's preserves, and as they split up the dainty succulent fruit, they liberate [and scatter] the seeds, and thus secure the prospect of

fresh generations of plants.—ANDREW WILSON *Glimpses of Nature,* ch. 22. p. 72. (Hum., 1892.)

538. COLOR OF PIGMENTS—*Absorption and Reflection Unite to Determine—The Rose Seen by Light Reflected Back through Its Substance—Exhaustion by Waste of Echoes.*—Pigments are composed of particles mixed with a vehicle: but how intimately soever the particles may be blended, they still remain particles, separated it may be by exceedingly minute distances, but still separated. To use the scientific phrase, they are not optically continuous. Now, wherever optical continuity is ruptured we have reflection of the incident light. It is the multitude of reflections at the limiting surfaces of the particles that prevents light from passing through glass, or rock salt, when these transparent substances are pounded into powder. The light here is exhausted in a waste of echoes, not extinguished by true absorption. It is the same kind of reflection that renders the thunder-cloud so impervious to light. Such a cloud is composed of particles of water mixed with particles of air, both separately transparent, but practically opaque when thus mixed together. In the case of pigments, then, the light is reflected at the limiting surfaces of the particles, but it is in part absorbed within the particles. The reflection is necessary to send the light back to the eye; the absorption is necessary to give the body its color. The same remarks apply to flowers. The rose is red in virtue, not of the light reflected from its surface, but of light which has entered its substance, which has been reflected from surfaces within, and which in returning through the substance has had its green extinguished. A similar process in the case of hard green leaves extinguishes the red, and sends green light from the body of the leaves to the eye. —TYNDALL *Lectures on Light,* lect. 1, p. 34. (A., 1898.)

539. COLOR OF THE SKY—*Hues of Flowers Due to Absorption—Fine Particles Make Blue of Sky—Alpine Sunrise and Sunset.*—First, then, with regard to the sky: how is it produced, and can we not reproduce it? Its color has not the same origin as that of ordinary coloring matter, in which certain portions of the white solar light are absorbed, the color of the body being that of the light which remains. A violet is blue because its molecular texture enables it to quench the yellow and red constituents of white light, and to send back the blue from its interior. A geranium is red because its molecular texture is such as quenches all rays except the red. Such colors are called colors of absorption; but the hue of the sky is not of this character. The blue light of the sky is scattered light; and, were there nothing in our atmosphere competent to scatter the solar rays, we should see no blue firmament, but the mere darkness of infinite space. The blue of the sky is produced by perfectly colorless particles. Smallness of size alone is requisite to insure the selection and reflection of this color. Of all the visual waves emitted by the sun, the shortest and smallest are those corresponding to the color blue. To such small waves minute particles offer more obstruction than to large ones, hence the predominance of blue color in all light reflected from such particles. The crimson glow of the evening and the morning, seen so finely in the Alps, is due, on the other hand, to transmitted light; that is to say, to light which, in its passage through great atmospheric distances, has its blue constituents sifted out of it by repeated collision with suspended particles.—TYNDALL *Heat a Mode of Motion,* lect. 16, p. 484. (A., 1900.)

540. ——— ——— *May Be Produced Artificially—Light Liberates Atoms from Vapor.*—We can liberate, in air, particles of a size capable of producing a blue as deep and pure as the azure of the firmament. In fact, artificial skies may be thus generated, which prove their brotherhood with the natural sky by exhibiting all its phenomena. There are certain chemical compounds—aggregates of molecules—the constituent atoms of which are readily shaken asunder by the impact of special waves of light. Probably, if not certainly, the atoms and the waves are so related to each other, as regards vibrating period, that the wave-motion can accumulate until it becomes disruptive. A great number of substances might be mentioned whose vapors, when mixed with air and subjected to the action of a solar or an electric beam, are thus decomposed, the products of decomposition hanging as liquid or solid particles in the beam which generates them. . . . Like the natural sky, the artificial one shows all the colors of the spectrum, but blue in excess.—TYNDALL *Fragments of Science,* vol. i, ch. 5, p. 137. (A., 1897.)

541. COLORATION, PROTECTIVE, UNIVERSAL—*Natural Objects of Every Kind Imitated by Living Beings.*—Protective coloration, in some of its varied forms, has not improbably modified the appearance of one-half of the animals living on the globe. The white of arctic animals, the yellowish tints of the desert forms, the dusky hues of crepuscular and nocturnal species, the transparent or bluish tints of oceanic creatures, represent a vast host in themselves; but we have an equally numerous body whose tints are adapted to tropical foliage, to the bark of trees, or to the soil or dead leaves on or among which they habitually live. Then we have the innumerable special adaptations to the tints and forms of leaves, or twigs, or flowers; to bark or moss; to rock or pebble; by which such vast numbers of the insect tribes obtain protection: and these various forms of coloration are equally prevalent in

the waters of the seas and oceans, and are thus coextensive with the domain of life upon the earth.—WALLACE *Darwinism*, ch. 8, p. 155. (Hum., 1889.)

542. COLOR-BLINDNESS—*More Common among Men than among Women—Defect Commonly Congenital.*—Color-blindness is found much more common among men than women. Out of one hundred and fifty registered cases, there are but six of females, and one of these is doubtful. It has been conjectured that needlework on a variety of colored articles might be the means of counteracting the tendency to this defect, as well as to produce a delicacy of discrimination of different shades of color not possessed by those otherwise employed. But in answer to this it has been remarked, that in the case of "Daltonians" engaged in painting there has been found but little, if any, improvement of the condition of vision; and the very employment of the females on works which require a constant comparison of color would daily reveal cases of blindness of this kind did it frequently exist in the female sex. This peculiarity of vision is principally congenital. Professor Wartmann has found but two exceptions. In one of these, colors were perceived in the usual manner until at the ninth year, when the boy received a violent blow on the head, which fractured the skull, and rendered a surgical operation necessary. The fact, however, that three of the brothers of this individual were affected with the same kind of vision renders it probable that he was constitutionally predisposed to this peculiarity. —HENRY *Scientific Works*, vol. i, p. 238. (Sm. Inst., 1886.)

543. COLORS IN DEEP-SEA FISH—*Dark or Dull Hues Prevail.*—The majority of the fish are dark brown or black, but many other colors are represented. . . . Many examples could be given to show the prevalence in these regions of these black, dull, and pale uniform colors. But there are many exceptional cases.—HICKSON *Fauna of the Deep Sea*, ch. 4, p. 59. (A., 1894.)

544. COLORS OBTAINED FROM THIN FILMS—*Due to Interference of Light-waves.*—He [Robert Hooke] then describes fully and clearly the experiment with pressed glasses: "Take two small pieces of ground and polished looking glass plate, each about the bigness of a shilling; take these two dry, and with your forefingers and thumbs press them very hard and close together, and you shall find that when they approach each other very near there will appear several irises or colored lines, . . . and you may very easily change any of the colors of any part of the interposed body by pressing the plates closer and harder together, or leaving them more lax—that is, a part which appeared colored with a red may be presently tinged with a yellow, blue, green, purple, or the like. Any substance," he says, "provided it be thin and transparent, will show these colors." Like Boyle, he obtained them with glass films; he also "produced them with bubbles of pitch, rosin, colophony, turpentine, solutions of several gums, as gum arabic in water, any glutinous liquor, as wort, wine, spirit of wine, oil of turpentine, glare of snails, etc." [See COLORS OF THIN PLATES, 548-9.]—TYNDALL *Lectures on Light*, lect. 2, p. 70. (A., 1898.)

545. COLORS OF SPECTRUM—*Aristotle's Theory of Combination of Black and White—Experiment Disposes of Ancient Error.*—Aristotle taught that black and white are the two fundamental qualities of light, and that every color can be obtained from their intermixture in varying amounts. . . . The Aristotelian view of the origin of color prevailed until modern times. Goethe defended it, and many of his admirers are its enthusiastic champions. But it has been banished from science these two hundred years, thanks to Newton's discoveries. Newton said to himself: If there really are simple kinds of light or simple colors, which intermix in various ways, we must be able both to isolate and to recombine the simple constituents of any given compound color. That meant that the whole question was referred to the tribunal of experiment, where alone it could be definitely answered. For direct perception is deceptive. Can the chemist "see" of what elements a body is composed? Of course not. We know that bodies of very different chemical composition appear just alike. May not the same hold of light? May not similar kinds of light give rise to different mixtures, and different kinds to similar mixtures? So Newton looked round him for a means of analyzing compound light, and by a happy accident found what he wanted in the refraction of light by the prism.—WUNDT *Psychology*, lect. 6, p. 88. (Son. & Co., 1896.)

546. COLORS OF STARS—*Change of Color of Sirius.*—The Greek astronomers were acquainted with red stars only, while modern science has discovered, by the aid of the telescope, in the radiant fields of the starry heaven, as in the blossoms of the phanerogamia, and in the metallic oxids, almost all the gradations of the prismatic spectrum between the extremes of refrangibility of the red and the violet ray. Ptolemy enumerates in his catalog of the fixed stars six (ὑποκίρροι) fiery red stars—viz., Arcturus, Aldebaran, Pollux, Antares, α Orionis (in the right shoulder), and Sirius. Cleomedes even compares Antares in Scorpio with the fiery red Mars, which is called both πυῤῥός and πυροειδής. Of the six above-named stars, five still retain a red or reddish light. Pollux is still indicated as a reddish but Castor as a greenish star. Sirius therefore affords the only example of

an historically proved change of color, for it has at present a perfectly white light. A great physical revolution must therefore have occurred at the surface or in the photosphere of this fixed star.—HUMBOLDT *Cosmos*, vol. iii, p. 130. (H., 1897.)

547. ——— ——— *Variety and Contrast of—Instances of Double, Triple, and Multiple Stars.* — Stars have also been noticed which, instead of showing a white or golden light, as is generally the case, are colored with the most vivid tints, such as those of the emerald, sapphire, ruby, topaz, garnet, and the finest of our precious stones. The telescope has discovered a large number which, instead of being single, as they appear to the naked eye, are double, composed of two stars close together which turn round each other in revolutions which we have already been able to calculate, and which include the most varied periods, from a few years to several centuries and even thousands of years. Sometimes the system is triple: a bright star is seen accompanied by two little companions, and while these two revolve round each other, they move together and revolve round the large one. It is among these multiple systems that we find the most wonderful contrasts of colors. The science is already so far advanced in this respect that I have been able to form a catalog of nearly 1,000 double stars in certain motion, and to construct a chart of more than 10,000 double stars which have been discovered.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 3, p. 580. (A.)

548. COLORS OF THIN PLATES— *Films of Any Kind Illustrate—Newton Blowing Soap-bubbles.*—This subject [of the interference of light-waves] may be illustrated by the class of phenomena which first suggested the undulatory theory to the mind of Hooke. These are the colors of thin transparent films of all kinds, known as the colors of thin plates. In this relation no object in the world possesses a deeper scientific interest than a common soap-bubble. And here let me say emerges one of the difficulties which the student of pure science encounters in the presence of "practical" communities like those of America and England; it is not to be expected that such communities can entertain any profound sympathy with labors which seem so far removed from the domain of practise as many of the labors of the man of science are. Imagine Dr. Draper spending his days in blowing soap-bubbles and in studying their colors! Would you show him the necessary patience, or grant him the necessary support? And yet, be it remembered, it was thus that minds like those of Boyle, Newton, and Hooke were occupied; and that on such experiments has been founded a theory the issues of which are incalculable. I see no other way for you, laymen, than to trust the scientific man with the choice of his inquiries; he stands before the tribunal of his peers, and by their verdict on his labors you ought to abide.—TYNDALL *Lectures on Light*, lect. 2, p. 65. (A., 1898.)

549. ——— ——— *Interference of Light-waves Illustrated—Prismatic Colors of a Film of Spirit of Turpentine on Water.*—Take with you a little bottle of spirit of turpentine, and pour it into one of your country ponds. You will then see the flashing of those colors over the surface of the water. On a small scale we produce them thus: A common tea-tray is filled with water, beneath the surface of which dips the end of a pipette. A beam of light falls upon the water, and is reflected by it to the screen. Spirit of turpentine is poured into the pipette; it descends, issues from the end in minute drops, which rise in succession to the surface. On reaching it, each drop spreads suddenly out as a film, and glowing colors immediately flash forth upon the screen. The colors change as the thickness of the film changes by evaporation. They are also arranged in zones, in consequence of the gradual diminution of thickness from the center outwards. [See COLORS OBTAINED FROM THIN FILMS; LIGHT, DOUBLE REFLECTION OF, PLATES; etc.]—TYNDALL *Lectures on Light*, lect. 2, p. 67. (A., 1898.)

550. COLORS RESULTING FROM MOLECULAR ARRANGEMENT OF SUBSTANCES—It is the molecular arrangement of reflecting or transparent substances which gives rise to the different reflections of light—that is to say, the colors. A slight difference produces here a blue eye, pensive and thoughtful, there a brown eye with half-hidden flames, there a look dull and distasteful. The dazzling rose which blooms in the flower-garden receives the same light as the lily, the buttercup, the cornflower, or the violet; molecular reflection produces all the difference; and we might even say, without metaphor, that objects are of all colors except that which they appear. Why is the meadow green? Because it keeps all except the green, which it does not want, and sends back. White is formed by the reflective nature of an object which keeps nothing and returns all: black, by a surface which keeps all and sends back nothing.—FLAMMARION *Popular Astronomy*, bk. iii, ch. 7, p. 321. (A.)

551. COMBINATION MAY PERISH— *Substance or Agent Must Remain.*—There is no existing order—no present combination of matter or of force—which we cannot conceive coming to an end. But when that end is come, we cannot conceive but that something must remain—if it be nothing else than that by which the ending was brought about.—ARGYLL *Unity of Nature*, ch. 4, p. 85. (Burt.)

552. COMBINATION OF INTELLIGENCE— *The Republic of the Stars—By Electricity the Astronomer Looks from All Parts of the World at Once.*—Modern facilities of communication have helped to impress more

deeply upon modern astronomy its associative character. The electric telegraph gives a certain ubiquity which is invaluable to an observer of the skies. With the help of a wire, a battery, and a code of signals, he sees whatever is visible from any portion of our globe, depending, however, upon other eyes than his own, and so entering as a unit into a wide-spread combination of intelligence. The press, again, has been a potent agent of cooperation. I has mainly contributed to unite astronomers all over the world into a body animated by the single aim of collecting "particulars" in their special branch for what Bacon termed a History of Nature, eventually to be interpreted according to the sagacious insight of some one among them gifted above his fellows.—CLERKE *History of Astronomy*, int., p. 7. (Bl., 1893.)

553. COMBINATION OF THE SEEMINGLY INCOMPATIBLE — *Fossils Ejected from Depths of Volcano.*—At Vesuvius fragments of limestone are frequently ejected, and may be picked up all over the slopes of the mountains. These limestone-fragments frequently contain fossils, and Professor Guiscardi, of Naples, has been able to collect several hundred species of shells, transported thus by volcanic action from the rock-masses which form the foundation of the volcano of Vesuvius. The action of water at a high temperature, and under such enormous pressure as must exist beneath volcanic mountains, has often produced changes in the rocks of which fragments are ejected from volcanic vents.—JUDD *Volcanoes*, ch. 3, p. 45. (A., 1899.)

554. COMBINATIONS, HUMAN, MUST ACT WITH NATURE—Combination is natural to man. The desire for it and the need of it grow with the growth of knowledge and with the increasing complications of society. It has now, for the most part, emerged from the stage of rude ignorance which led to the breaking of machinery. It is conducted, comparatively at least, with high intelligence, and aims for the most part at legitimate objects of desire. Yet in the rebellion which has been roused against the doctrines of necessity, founded on false conceptions of invariable law, there is a constant danger lest the spirit of association should attempt to act against Nature, instead of acting with it.—ARGYLL *Reign of Law*, ch. 7, p. 224. (Burt.)

555. COMBUSTION, ITS CHIEF PRODUCTS INVISIBLE—The chief products of ordinary combustion—that is, the compounds of oxygen with the elements of coal, wood, and illuminating gas—are only two in number, carbonic dioxid gas and aqueous vapor. These products, as is well known, are perfectly colorless and transparent aeriform substances, wholly without odor or taste, and entirely devoid of every active quality. For this reason they escape without observation from the burning wood, ascend our chimneys, and by the force of diffusion are spread throughout the atmosphere; but if, as may readily be done by chemical means, we collect the neglected smoke and weigh it, we shall find that it weighs much more than the burnt wood, and, as more careful experiments will show, its weight is exactly equal to that of the wood added to that of the oxygen of the air consumed during the burning.—COOKE *Religion and Chemistry*, ch. 3, p. 78. (A., 1897.)

556. COMETS ARE MOVING ELECTRIC LIGHTS—The gaseous surroundings of comets are then largely made up of a compound of hydrogen with carbon. Other materials are also present; but the hydrocarbon element is probably unfailing and predominant. Its luminosity is, there is little doubt, an effect of electrical excitement. Zöllner showed in 1872 that, owing to evaporation and other changes produced by rapid approach to the sun, electrical processes of considerable intensity must take place in comets; and that their original light is immediately connected with these, and depends upon solar radiation, rather through its direct or indirect electrifying effects than through its more obvious thermal power may be considered a truth permanently acquired to science. They are not, it thus seems, bodies incandescent through heat, but glowing by electricity; and this is compatible, under certain circumstances, with a relatively low temperature.—CLERKE *History of Astronomy*, pt. ii, ch. 10, p. 416. (Bl., 1893.)

557. COMMUNICATION, ELECTRICAL—*Vision of a Possible Future.*—In a lecture on Submarine Telegraphy at the Imperial Institute (February 15, 1897), Professor Ayrton said: "I have told you about the past and about the present. What about the future? Well, there is no doubt the day will come, maybe when you and I are forgotten, when copper wires, gutta-percha coverings, and iron sheathings will be relegated to the museum of antiquities. Then, when a person wants to telegraph to a friend, he knows not where, he will call in an electro-magnetic voice, which will be heard loud by him who has the electro-magnetic ear, but will be silent to every one else. He will call, 'Where are you?' and the reply will come, 'I am at the bottom of the coal-mine,' or 'Crossing the Andes,' or 'In the middle of the Pacific'; or perhaps no reply will come at all, and he may then conclude the friend is dead."—FAHIE *Wireless Telegraphy*, pref., p. 7. (D. M. & Co., 1900.)

558. COMMUNION OF PRIMITIVE MAN WITH NATURE—*Astronomy the Most Ancient of the Sciences—The Moon's Phases the Origin of the Calendar—"He Appointed the Moon for Seasons" (Ps. civ. 19).*—Our forefathers lived in more intimate com-

munication with Nature than we do. They had neither the artificial life, nor the hypocrisy, nor the anxieties created by the factitious necessities of modern existence. It was they who established the first bases of the sciences by the direct observation of natural phenomena. If astronomy is the most ancient of the sciences, the study of the moon was the most ancient of astronomical observations, because it was the simplest, the easiest, and the most useful. The solitary globe of night pours out its calm and clear light in the midst of the silence and contemplation of Nature. The succession of its phases provided shepherds as well as travelers with the first measure of time, after that of day and night, due to the diurnal rotation of our planet. The lunar crescent, with its melancholy light, gave to Nature a pastoral calendar.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 2, p. 96. (A.)

559. COMMUNITY OF NEED AND SUPPLY—*Chopping-knife in Use among Eskimo Women.*—The Eskimo women have a knife precisely like the mincing-choppers in every kitchen, which they use at present for all sorts of work. But is it not interesting to find dainty little women almost at the jumping-off place of the globe holding on to the primeval form of an implement as well as its use whose modern representative does service both in our kitchens and our saddler-shops? The saddler and his wife now divide between them an implement which many thousands of years ago would have been hers alone, and he would have been defiled to touch it. With it, in that early day, she made harness for dogs and for herself to wear, besides cutting out clothing and tents, skinning animals, and mincing food.—MASON *Woman's Share in Primitive Culture*, ch. 2, p. 27. (A., 1894.)

560. COMPARISON OF DIFFERENT VIEWS—*Celestial Objects Located by Combining Observations—Transit of Venus—The Planet a Celestial Index.*—To determine the distance of an inaccessible object we must compare the direction in which it lies as seen from two stations sufficiently far apart. This, which is a principle of ordinary land-surveying, is equally true of the celestial objects. The astronomer determines the moon's distance by observing her from the northern and southern hemispheres, as from the Greenwich Observatory and the observatory at Cape Town; or else he takes advantage of the fact that the earth rotates on her axis, and so carries any given station from one side to another in a given time. The distance of the sun can be measured in no other (direct) way, and altho we hear of the transits of Venus as means of which the astronomer avails himself to determine the sun's distance, yet the very same principle is involved—the value of a transit of Venus depending solely on the fact that the observers at two distant stations can in point of fact regard her as a celestial index, traversing the sun's face as an index-plate, so that they possess, as it were, an instrument of survey more powerful than any terrestrial instrument.—PROCTOR *Expanse of Heaven*, p. 241. (L. G. & Co., 1897.)

561. COMPENSATION IN CHRONOMETER—*Self-adjustment to Heat or Cold—Cause Back of Mechanism.*—We find a singularly parallel case in that beautiful piece of human workmanship—a clock or chronometer so constructed as, by the accurate "compensation" of its pendulum or balance-wheel, to keep accurate time under all ordinary variations of climatic temperature. Surely we do not consider it a sufficient account of its self-adjustment to attribute it to the physical action of heat or cold: for this would disturb the performance of an ordinary clock or watch. We seek the explanation of its special "potentiality" in the compensating apparatus; and we trace back the origin of this apparatus to the mind of its contriver. So, as it seems to me, however long may be the chain of "causation," or the series of "unconditional sequences," that may be traceable backwards in the ancestral history of any organized type, we come to a beginning of it, as to the first term of an arithmetical or geometrical progression; and we have no less to account for the common beginning of the whole organized creation, with its unlimited possibilities of modification and adaptation, than if we had to account for the separate production of each type of plant and animal.—CARPENTER *Nature and Man*, lect. 15, p. 442. (A., 1889.)

562. COMPENSATION IN NATURE—*Insectivorous Plants Flourish in Poor Soil—Interchange of Functions of Organs—Roots Defective when Leaves Supply Food.*—The absorption of animal matter from captured insects explains how Drosera can flourish in extremely poor peaty soil. . . . Altho the leaves at a hasty glance do not appear green, owing to the purple color of the tentacles, yet the upper and lower surfaces of the blade, the pedicels of the central tentacles, and the petioles contain chlorophyl, so that, no doubt, the plant obtains and assimilates carbonic acid from the air. Nevertheless, considering the nature of the soil where it grows, the supply of nitrogen would be extremely limited, or quite deficient, unless the plant had the power of obtaining this important element from captured insects. We can thus understand how it is that the roots are so poorly developed. These usually consist of only two or three slightly divided branches, from half to one inch in length, furnished with absorbent hairs. It appears, therefore, that the roots serve only to imbibe water; tho, no doubt, they would absorb nutritive matter if present in the soil. . . . A plant of Drosera, with the edges of its leaves curled inwards, so as to form a temporary stomach, with the

glands of the closely inflected tentacles pouring forth their acid secretion, which dissolves animal matter, afterwards to be absorbed, may be said to feed like an animal. But, differently from an animal, it drinks by means of its roots; and it must drink largely, so as to retain many drops of viscid fluid round the glands, sometimes as many as 260, exposed during the whole day to a glaring sun.—DARWIN *Insectivorous Plants*, ch. 1, p. 14. (A., 1900.)

563. COMPENSATIONS OF THE DEEP—*Lack of Sight Accompanied by Superior Organs of Touch.*—The disappearance of the sense of sight in the animals of the deep sea is sometimes accompanied by an enormous development of tactile organs. Thus, among fishes we find *Bathypterois*, a form that possesses extremely small eyes, provided with enormously long pectoral fin-rays that most probably possess the functions of organs of touch. Among the Crustacea we find the blind form, *Galathodes Antonii*, with an extraordinary development in length of the antennæ, and *Nematocarcinus*, with enormously long antennæ and legs.—HICKSON *Fauna of the Deep Sea*, ch. 4, p. 75. (A., 1894.)

564. COMPETITORS, NEW, AFFECT PLANT OR ANIMAL IN NEW LAND—Hence we can see that when a plant or animal is placed in a new country, among new competitors, the conditions of its life will generally be changed in an essential manner, altho the climate may be exactly the same as in its former home. If its average numbers are to increase in its new home, we should have to modify it in a different way to what we should have had to do in its native country; for we should have to give it some advantage over a different set of competitors or enemies.—DARWIN *Origin of Species*, ch. 3, p. 72. (Burt.)

565. COMPLEXITY OF CONSCIOUSNESS ALWAYS—*No Feeling or Motive Simple and Unmingled.*—We have thus fields of consciousness—that is the first general fact; and the second general fact is that the concrete fields are always complex. They contain sensations of our bodies and of the objects around us, memories of past experiences and thoughts of distant things, feelings of satisfaction and dissatisfaction, desires and aversions, and other emotional conditions, together with determinations of the will, in every variety of permutation and combination.—JAMES *Talks to Teachers*, ch. 2, p. 17. (H. H. & Co., 1900.)

566. COMPLEXITY OF HUMAN BRAIN AND FINENESS OF STRUCTURE—*Adapted to Freedom and Variety of Human Thought.*—When it is remembered, indeed, that the brain itself is very large, the largest mass of nerve-matter in the organic world; when it is further realized that each of the cells of which it is built up measures only one-ten-thousandth of an inch in diameter, that the transit-fibers which connect them are of altogether unimaginable fineness, the limitlessness of the powers of thought and the inconceivable complexity of these processes will begin to be understood.—DRUMMOND *Ascent of Man*, p. 286. (J. P., 1900.)

567. COMPLEXITY OF THE STRUGGLE FOR LIFE—*Humblebees—Field-mice—Cats.*—Humblebees alone visit red clover, as other bees cannot reach the nectar. . . . Hence we may infer as highly probable that, if the whole genus of humblebees became extinct or very rare in England, the red clover would become very rare, or wholly disappear. The number of humblebees in any district depends in a great measure upon the number of field-mice, which destroy their combs and nests; and Colonel Newman, who has long attended to the habits of humblebees, believes that "more than two-thirds of them are thus destroyed all over England." Now the number of mice is largely dependent, as every one knows, on the number of cats. . . . Hence it is quite credible that the presence of a feline animal in large numbers in a district might determine, through the intervention first of mice and then of bees, the frequency of certain flowers in that district.—DARWIN *Origin of Species*, ch. 1, p. 68. (Burt.)

568. COMPLEXITY REQUIRES TIME FOR DEVELOPMENT—Two organisms of the same size, but belonging to different grades of organization, will require different periods of time for their development. Certain animals of a very lowly organization, such as the Rhizopoda, may attain a diameter of .5 mm. and may thus become larger than many insects' eggs. Yet under favorable circumstances an ameba can divide into two animals in ten minutes, while no insect's egg can develop into the young animal in a less period than twenty-four hours. Time is required for the development of the immense number of cells which must in the latter case arise from the single egg-cell.—WEISMANN *Heredity*, vol. i, ch. 1, p. 8. (Cl. P., 1891.)

569. COMPOSITION OF FORCES—*Path of a Pendulum Changed to an Ellipse.*—Suspended before you is a pendulum, which, when drawn aside and liberated, oscillates to and fro. If, when the pendulum is passing the middle point of its excursion, I impart a shock to it tending to drive it at right angles to its present course, what occurs? The two impulses compound themselves to a vibration oblique in direction to the former one, but the pendulum still oscillates in a plane. But, if the rectangular shock be imparted to the pendulum when it is at the limit of its swing, then the compounding of the two impulses causes the suspended ball to describe, not a straight line, but an ellipse; and, if the shock be competent of itself to produce a vibration of the

same amplitude as the first one, the ellipse becomes a circle.—TYNDALL *Lectures on Light*, lect. 4, p. 142. (A., 1898.)

570. COMPREHENSIVENESS OF GENIUS—*Newton Proved Gravitation by Studying the Disturbances of the Moon's Motion.*—It was in dealing with these disturbances [of the moon] that Newton showed with what wonderful mental powers he had been endowed. He tracked the moon through all her movements, and measured the sun's action on her in all positions; he showed where she would be hastened, where retarded, where drawn away from the earth, where drawn closer, where her path would be more tilted, where less, where its eccentricity would be increased, where diminished. All the peculiarities of motion thus calculated from the law of gravitation were found to accord in the most convincing manner with those peculiarities actually observed in the moon's motions which had long perplexed astronomers. The demonstration of the law of gravitation was so complete, as it thus first came from Newton's hands, that within a very short time men of science were thoroughly convinced, and the law of gravitation has not been seriously questioned from that day to this.—PROCTOR *Expanse of Heaven*, p. 113. (L. G. & Co.)

571. COMPREHENSIVENESS OF THE HUMAN MIND—*Man Reads System into Phenomena.*—Through this faculty of invention the whole earth is man's. There is not a lone island fit for his abode whereon some Alexander Selkirk has not made a home. Every mineral, plant, and animal is so far known that a place has been found for it in his *Systema Naturæ*. Every creature is subject to man; the winds, the seas, the sunshine, the lightning do his bidding. Projecting his vision beyond his tiny planet, this inventing animal has catalogued and traced the motion of every star. But his crowning glory (which always fills me with admiration) is his ever-increasing comprehensiveness. After centuries of cultivating acquaintance with the discrete phenomena around him, he has now striven to coordinate them, to make them organic, to read system into them. He has learned by degrees to comprehend all things as parts of a single mechanism. Sir Isaac Newton and Kepler conceived all objects and all worlds to be held by universal gravitation.—MASON *The Birth of Invention. Address at Centenary of Am. Pat. System, Washington, D. C., 1891;* proceedings, p. 403.

572. COMPULSION ABOLISHES MORAL QUALITY OF ACTIONS—If any human action is determined not by any motive whatever, but simply by external or physical compulsion, then no moral element is present at all, and no perception of the moral sense can arise respecting it. Freedom, therefore, in the sense of exemption from such compulsion, must be assumed as a condition of human action absolutely essential to its possessing any moral character whatever.—ARGYLL *Unity of Nature*, ch. 9, p. 197. (Burt.)

573. COMPULSION OF BODY BY MIND—*The "Mountain Sickness"—Milk Refreshes Alpine Climber.*—It is not good to go altogether without food in these climbing expeditions; nor is it good to eat copiously. Here a little and there a little, as the need makes itself apparent, is the prudent course. For, left to itself, the stomach infallibly sickens, and the forces of the system ooze away. Should the sickness have set in so as to produce a recoil from nutriment, the stomach must be forced to yield. A small modicum of food usually suffices to set it right. The strongest guides and the sturdiest porters have sometimes to use this compulsion. . . . On the present occasion I had a bottle of milk, which suits me better than anything else. That and a crust are all I need to keep my vigor up and to ward off *le mal des montagnes.*—TYNDALL *Hours of Exercise in the Alps*, ch. 25, p. 302. (A., 1898.)

574. CONCENTRATION OF INDUSTRY—*The Factory System Antedates Steam—Apprenticeship an Incident.*—And just as Hargreaves and Arkwright and Crompton were inventing the new machines which were to be moved, Watt was laboring at the new power which was to move them. But meanwhile, before the steam-engine had been made available, the factory system had begun under the old motive power of water; and here it is very curious to observe how each stage in the progress of discovery had, by way of natural consequence, its own special effect on the conduct and the wills of men. Very soon the course of every mountain stream in Lancashire and Yorkshire was marked by factories. This again had another consequence. It was a necessity of the case that such factories must generally be situated at a distance from preexisting populations, and, therefore, from a full supply of labor. Consequently they had to create communities for themselves. From this necessity, again, it arose that the earlier mills were worked under a system of apprenticeship. The due attendance of the requisite number of "hands" was secured by engagements which bound the laborer to his work for a definite period.—ARGYLL *Reign of Law*, ch. 7, p. 207. (Burt.)

575. CONCENTRATION OF POWER—*Through a Three-foot Burning-glass the Sun's Heat Vaporizes Diamond—A Partial Revelation of the Heat of the Sun's Surface—Source of Heat Exceeds Its Reflection or Refraction.*—One certain thing is this—that we cannot by any contrivance raise the temperature in the focus of any lens or mirror beyond that of its source (practically we cannot do even so much); we cannot, for instance, by any burning-lens make the

image of a candle as hot as the original flame. Whatever a thermometer may read when the candle-heat is concentrated on its bulb by a lens, it would read yet more if the bulb were dipped in the candle-flame itself; and one obvious application of this fact is that tho we cannot dip our thermometer in the sun, we know that if we could do so the temperature would at least be greater than any we get by the largest burning-glass. We need have no fear of making the burning-glass too big; the temperature at its solar focus is always and necessarily lower than that of the sun itself.

For some reason no very great burning-lens or mirror has been constructed for a long time, and we have to go back to the eighteenth century to see what can be done in this way. . . .

In England, the largest burning-lens on record was made . . . by an optician named Parker for the English Government, who designed it as a present to be taken by Lord Macartney's embassy to the Emperor of China. Parker's lens was three feet in diameter and very massive, being seven inches thick at the center. In its focus the most refractory substances were fused, and even the diamond was reduced to vapor, so that the temperature of the sun's surface is at any rate higher than this.—LANGLEY *New Astronomy*, ch. 4, p. 102. (H. M. & Co.)

576. CONCEPTION, INFINITE, FROM FINITE EXPERIENCE—*Indestructibility of Matter and of Force.*—It is indeed of the highest importance to observe that some of these conceptions, especially the indestructibility of matter and of force, belong to the domain of science. . . . As now accepted and defined, they are the result of direct experiment. And yet, strictly speaking, all that experiment can do is to prove that in all the cases in which either matter or force seems to be destroyed, no such destruction has taken place. Here then we have a very limited and imperfect amount of "experience" giving rise to an infinite conception. But it is another of the suggestions of the agnostic philosophy that this can never be a legitimate result. Nevertheless, it is a fact that these conceptions have been reached. They are now universally accepted and taught as truths lying at the foundation of every branch of natural science—at once the beginning and the end of every physical investigation.—ARGYLL *Unity of Nature*, ch. 4, p. 85. (Burt.)

577. CONCEPTION OF A FINITE CREATOR—*God Himself Viewed as Engaged in the Struggle against Inevitable Evil—Mill's Belief.*—He [John Stuart Mill] does not undertake to suggest how or why the divine power is limited; but he distinctly prefers the alternative which sacrifices the attribute of omnipotence in order to preserve in our conception of Deity the attribute of goodness. According to Mr. Mill, we may regard the all-wise and holy Deity as a creative energy that is perpetually at work in eliminating evil from the universe. His wisdom is perfect, his goodness is infinite, but his power is limited by some inexplicable viciousness in the original constitution of things which it must require a long succession of ages to overcome. In such a view Mr. Mill sees much that is ennobling. The humblest human being who resists an impulse to sin, or helps in the slightest degree to leave the world better than he found it, may actually be regarded as a participator in the creative work of God; and thus each act of human life acquires a solemn significance that is almost overwhelming to contemplate.—FISKE *Through Nature to God*, pt. i, ch. 3, p. 17. (H. M. & Co., 1900.)

578. CONCEPTIONS FOUNDED ON EXPERIENCE—*The "Falling Atoms" of Ancient Philosophy.*—Our conceptions of natural phenomena and their causes are founded on, but they are not bounded by, sensible experience. The eternally falling atoms of Epicurus and Lucretius, for example, were derived from the observation of small particles of matter; but in transforming such particles, by a mental act, into atoms, the ancient philosophers broke ground in an ideal region. The notion of falling indicates the manner in which the ancient mind was conditioned by experience; for in those days, while the action of gravity was known, the action of molecular force, capable of attracting and arranging the atoms, was unknown. The case is representative, the visible world being converted by science into the symbol of an invisible one. We can have no explanation of the objects of experience, without invoking the aid and ministry of objects which lie beyond the pale of experience. We can only reach the roots of natural phenomena by laying down, intellectually, a subsensible soil out of which such phenomena spring.—TYNDALL *Heat a Mode of Motion*, lect. 1, p. 32. (A., 1900.)

579. CONCURRENCE OF EVENTS TO ADVANCE ASTRONOMY—*The "Set Time" of a Great Movement—Herschel "Bursts the Barriers of Heaven."*—Much of this interest was due to the occurrence of events calculated to arrest the attention and excite the wonder of the uninitiated. The predicted return of Halley's comet in 1759 verified, after an unprecedented fashion, the computations of astronomers. It deprived such bodies forever of their portentous character; it ranked them as denizens of the solar system. Again, the transits of Venus in 1761 and 1769 were the first occurrences of the kind since the awakening of science to their consequence. Imposing preparations, journeys to remote and hardly accessible regions, official expeditions, international communications, all for the purpose of observing them to the best advantage, brought their high significance vividly to the public consciousness; a result aided

by the facile pen of Lalande, in rendering intelligible the means by which these elaborate arrangements were to issue in an accurate knowledge of the sun's distance. Lastly, Herschel's discovery of Uranus, March 13, 1781, had the surprising effect of utter novelty. Since the human race had become acquainted with the company of the planets, no addition had been made to their number. The event thus broke with immemorial traditions, and seemed to show astronomy as still young and full of unlooked-for possibilities.—CLERKE *History of Astronomy*, int., p. 5. (Bl., 1893.)

580. CONDEMNATION OF PRESENT JUDGES BRAVED FOR HIGHER APPROVAL (*1 Cor. iv, 3-4*)—*The Highest, God—The "Great Companion."*—When for motives of honor and conscience I brave the condemnation of my own family, club, and "set"; when, as a Protestant, I turn Catholic; as a Catholic, freethinker; as a "regular practitioner," homeopath, or what not, I am always inwardly strengthened in my course and steeled against the loss of my actual social self by the thought of other and better possible social judges than those whose verdict goes against me now. The ideal social self which I thus seek in appealing to their decision may be very remote: it may be represented as barely possible. I may not hope for its realization during my lifetime; I may even expect the future generations, which would approve me if they knew me, to know nothing about me when I am dead and gone. Yet still the emotion that beckons me on is indubitably the pursuit of an ideal social self, of a self that is at least worthy of approving recognition by the highest possible judging companion, if such companion there be. This self is the true, the intimate, the ultimate, the permanent Me which I seek. This judge is God, the Absolute Mind, the "Great Companion."—JAMES *Psychology*, vol. i, ch. 10, p. 315. (H. H. & Co., 1899.)

581. CONDITIONS APPARENTLY SIMILAR PRODUCE DIFFERENT RESULTS—*In Coldest Siberia Glaciers Unknown—Hasty Inferences Untrustworthy.*—A study of the arctic regions quickly impresses one fact upon our minds, viz., the markedly unequal distribution of the larger masses of land-ice. . . . The other islands north of the American continent, tho some are of a fair size and rise to a considerable elevation, nowhere exhibit an accumulation of ice in any way comparable with that of Greenland. The same is true of the northern part of Siberia; the cold there is no less intense than in the north of the other continent. . . . The January temperature of Yakutsk, in latitude 62° north, is as low as — 40° F., and the soil is permanently frozen to a depth of about 700 feet. Yet in all this region, notwithstanding the intense cold, glaciers are unknown. The reason is simple: the air is dry and the snowfall is but light. So far as temperature goes, a glacial epoch rules in Siberia, but no marks of ice-action will be left behind in the event of its departure.—BONNEY *Ice-work, Present and Past*, pt. i, ch. 2, p. 39. (A., 1896.)

582. CONFIDENCE IN COMMON SENSE—Common sense, however, universally feels that analogy is here a safer guide to truth than the skeptical demand for impossible evidence.—ROMANES *Animal Intelligence*, int., p. 6. (A., 1899.)

583. CONFLAGRATION OF A STAR—*News Centuries in Coming.*—Between thirty and fifteen minutes before midnight of May 12, 1866, Mr. John Birmingham, of Millbrook, near Tuam, in Ireland, saw with astonishment a bright star of the second magnitude unfamiliarly situated in the constellation of the Northern Crown. Four hours earlier, Schmidt, of Athens, had been surveying the same part of the heavens, and was able to testify that it was not visibly there; that is to say, a few hours, or possibly a few minutes, sufficed to bring about a conflagration the news of which may have occupied hundreds of years in traveling to us across space. . . . The chief of [the lines observed in the spectrum] agreed in position with lines of hydrogen; so that the immediate cause of the outburst was plainly perceived to have been the eruption, or ignition, of vast masses of that subtle kind of matter the universal importance of which throughout the cosmos is one of the most curious facts revealed by the spectroscope.—CLERKE *History of Astronomy*, pt. ii, ch. 12, p. 473. (Bl., 1893.)

584. ——— ——— *Sudden Brightness of "The Blaze Star"—Possible Conflagration of Our Sun—The "Day of Fire" on Earth.*—Years ago a star suddenly appeared in the constellation of the Northern Crown, shining as a star of the second magnitude. It was found that it occupied the same place as a star of the tenth magnitude, and no doubt now exists that it was this known faint star which had thus suddenly acquired a new brilliancy: for tho the star soon lost its great brightness, it can still be seen, as before, as a star of about the tenth magnitude. Now, when the star (appropriately called the Blaze Star) came to be examined with the spectroscope, it was found that a great portion of its light came from glowing hydrogen. Doubtless, by some circumstances the exact nature of which we shall never know, there had been a tremendous conflagration in that distant star. It was estimated that the brightness of the star increased fully eight hundredfold while this conflagration was in progress. If a change such as this took place in our own sun—and who shall say that such a change is impossible?—the prophecy of St. Peter would be fulfilled: "The day of the Lord will come as a thief in the night; in the

which the heavens shall pass away with a great noise; and the elements shall melt with fervent heat: the earth also and the works that are therein shall be burned up" [2 Peter iii, 10]. For aught that is certainly known, the mere daily continuance of the sun's light and heat may be due to causes which need only be excited to unusual activity to produce such a catastrophe. . . . Sometimes there are outbursts in the sun which suggest very significantly the possibility of much more terrible, because more general, catastrophes.—PROCTOR *Expanse of Heaven*, p. 199. (L. G. & Co., 1897.)

585. CONFLAGRATION ON THE SUN—" *A Prairie on Fire*"—*Chromosphere and Prominences.*—At its base [of the sun's corona], and in contact with the photosphere, is what resembles a sheet of scarlet fire. The appearance, which probably indicates a fact, is as if countless jets of heated gas were issuing through vents and spiracles over the whole surface, thus clothing it with flame which heaves and tosses like the blaze of a conflagration—" like a prairie on fire," to quote the vividly descriptive phrase of Professor Langley. This has received the name of chromosphere. . . .

Here and there masses of this hydrogen mixed with other substances rise to a great height, ascending far above the general level into the coronal regions, where they float like clouds, or are torn to pieces by contending currents. These cloud-masses are known as solar " prominences," or " protuberances," a non-committal sort of appellation applied in 1842, when they first attracted any considerable attention, and while it was a warmly disputed question whether they were solar, lunar, phenomena of our own atmosphere, or even mere optical illusions. It is unfortunate that no more appropriate and graphic name has yet been found for objects of such wonderful beauty and interest.—YOUNG *The Sun*, ch. 6, p. 192. (A., 1898.)

586. ——— ——— *Simultaneous and Wild Agitation of the Magnetic Needle—Aurora Borealis.*—On September 1, 1859, two astronomers, Carrington and Hodgson, were observing the sun, independently of each other, the first on a screen which received the image, the second directly through a telescope, when. in a moment, a dazzling flash blazed out in the midst of a group of spots. This light sparkled for five minutes above the spots without modifying their form, as if it were completely independent, and yet it must have been the effect of a terrible conflagration occurring in the solar atmosphere. Each observer ascertained the fact separately, and was for an instant dazzled. Now, here is a surprising coincidence: at the very moment when the sun appeared inflamed in this region the magnetic instruments of the Kew Observatory, near London, where they were observing, manifested a strange agitation; the magnetic needle jumped for more than an hour as if infatuated. Moreover, a part of the world was on that day and the following one enveloped in the fires of an aurora borealis, in Europe as well as in America. It was seen almost everywhere: at Rome, at Calcutta, in Cuba, in Australia, and in South America. Violent magnetic perturbations were manifested, and at several points the telegraph lines ceased to act. Why should these two curious events not be associated with each other?—FLAMMARION *Popular Astronomy*, bk. iii, ch. 5, p. 290. (A.)

587. CONFLICT OF TESTIMONY—*Personal Difference of Observation Universal among Astronomers.*—When the errors dependent upon accidental circumstances have all been eliminated, these measurements still show differences between different observers. They persist even when there is no external reason discoverable. The fact was first noticed in the annals of the Greenwich Observatory for 1795. The astronomer writes that he dismissed his assistant as unreliable because he had acquired the habit of seeing all stellar transits half a second too late. Not till many decades later was the scientific honor of the assistant vindicated. It was the celebrated German astronomer Bessel who proved that this difference between two observers is only a special case of a phenomenon of universal occurrence. Bessel compared his own results with those of other astronomers, and came to the surprising conclusion that it is hardly possible to find two observers who put the passage of a star at precisely the same time, and that the personal differences may amount to a whole second. These observations were confirmed at all observatories.—WUNDT *Human and Animal Psychology*, ch. 18, § 2, p. 268. (Son. & Co., 1898.)

588. ——— ——— *Surprise Disqualifies for Observation—Disagreement in First Accounts of the Sun's Halo.*—In this halo we notice tongues of fire which emanate from the sun and are contiguous to him. It was during the eclipse of July 8, 1842, that the attention of astronomers was first attracted to these prominences, which shoot forth round the moon like gigantic flames of a rose or peach color (they had already been seen with the naked eye, especially in 1239, in 1560, 1605, 1652, 1706, 1724, 1733, and 1766, but astronomers believed them to be optical illusions). The surprise produced by this unexpected phenomenon did not permit exact observations to be made, so that there was a complete disagreement between the different accounts. Baily noticed 'three enormous prominences, almost uniformly distributed on the same side.

Airy observed three, in the form of the teeth of a saw, but placed at the summit. Arago saw two at the lower part of the disk. At Verona these flames remained vis-

ible after the appearance of the sun.—FLAMMARION *Popular Astronomy*, bk. iii, ch. 4, p. 263. (A.)

589. ——— ——— *Unimpeachable Witnesses Disagree.*—The most extraordinary thing, however [in the eclipse of 1878, seen from Pike's Peak], was a beam of light, inclined at an angle of about forty-five degrees, about as wide as the sun, and extending to the distance of nearly six of its diameters on one side and over twelve on the other; on one side alone, that is, to the amazing distance of over ten million miles from its [the sun's] body. Substantially the same observation was made, as it appeared later, by Professor Newcomb, at a lower level. The direction, when more carefully measured, it was interesting to note, coincided closely with that of the zodiacal light, and a faint central rib added to its resemblance to that body. It is noteworthy, in illustration of what has already been said as to the conflict of ocular testimony, that tho I, with the great majority of observers below, saw only this beam, two witnesses whose evidence is unimpeachable, Professors Young and Abbe, saw a pale beam at right angles to it; and that one observer did not see the beam in question at all.—LANGLEY *New Astronomy*, ch. 2, p. 55. (H. M. & Co., 1896.)

590. CONFLICT, SEEMING, OF SCIENCE AND RELIGION—*Science Not to Be Silenced by Dogma.*—When, therefore, the disturbing elements of scientific assertion and inquiry shock the religious beliefs of the individual, the sect, or the nation at large, what procedure or line of conduct does it become every earnest and cultured person to follow? Certainly not that of bewailing the destruction, apparent or real, of his temples of belief; not that of bemoaning the razing to the ground of those tents wherein he has so long and comfortably dwelt; and not that, assuredly, of asserting that, because his fathers worshiped in this mountain or in that, he must therefore and of necessity do the same. No; if our beliefs are attacked, and if they are worth defending at all, let us be up and doing. Meet your opponents with their own weapons. Do not go forth with old dogmas to meet scientific truths, as with the armor of medieval times against the weapons of to-day. Study science for yourselves; meet scientific fact and assertion by counter-assertion and counter-fact. You will find that in science, more, perhaps, than in commonplace things, there are always two sides to every great question; and you will never fight or gain your battle more readily, or more honestly, than by testing every point by your own knowledge, and by opposing to the advance of your adversaries a barrier of like kind to that which forms their most potent means of offense.—ANDREW WILSON *Science Culture for the Masses*, p. 33. (Hum., 1888.)

591. CONNECTION OF PHYSICAL PHENOMENA — *The Study of Science — A Unity behind the Facts.*—In considering the study of physical phenomena, not merely in its bearings on the material wants of life, but in its general influence on the intellectual advancement of mankind, we find its noblest and most important result to be a knowledge of the chain of connection by which all natural forces are linked together and made mutually dependent upon each other; and it is the perception of these relations that exalts our views and ennobles our enjoyments. Such a result can, however, only be reaped as the fruit of observation and intellect, combined with the spirit of the age, in which are reflected all the varied phases of thought.—HUMBOLDT *Cosmos*, vol. i, int., p. 23. (H., 1897.)

592. CONQUEST HAS UNINTENDED RESULT—*Human Brotherhood Strangely Advanced by War.*—"The impetuous conquests of Alexander, the more politic and premeditated extension of territory made by the Romans, the wild and cruel incursions of the Mexicans, and the despotic acquisitions of the Incas, have in both hemispheres contributed to put an end to the separate existence of many tribes as independent nations, and tended at the same time to establish more extended international amalgamation. Men of great and strong minds, as well as whole nations, acted under the influence of one idea, the purity of which was, however, utterly unknown to them. It was Christianity which first promulgated the truth of its exalted charity, altho the seed sown yielded but a slow and scanty harvest. Before the religion of Christ manifested its form, its existence was only revealed by a faint foreshadowing presentiment. In recent times, the idea of civilization has acquired additional intensity, and has given rise to a desire of extending more widely the relations of national intercourse and of intellectual cultivation; even selfishness begins to learn that by such a course its interests will be better served than by violent and forced isolation. Language, more than any other attribute of mankind, binds together the whole human race. By its idiomatic properties it certainly seems to separate nations, but the reciprocal understanding of foreign languages connects men together, on the other hand, without injuring individual national characteristics." [Quoted from Wilhelm von Humboldt.]—HUMBOLDT *Cosmos*, vol. i, p. 359. (H., 1897.)

593. CONQUEST OF NATURE BY SAVAGE MAN—*A House and Feast in the South Sea Islands—Fire Kindled by Friction.*—By the aid of strips of bark for rope, the stems of bamboos for rafters, and the large leaf of the banana for a thatch, the Tahitians in a few minutes built us an excellent house, and with withered leaves made a soft bed. They then proceeded to make a fire and cook our evening meal. A light was procured by rubbing a blunt-pointed stick in a groove made in another,

as if with intention of deepening it, until by the friction the dust became ignited. A peculiarly white and very light wood is alone used for this purpose. . . . The fire was produced in a few seconds; but to a person who does not understand the art, it requires, as I found, the greatest exertion; but at last, to my great pride, I succeeded in igniting the dust. . . . The Tahitians, having made a small fire of sticks, placed a score of stones, of about the size of cricket-balls, on the burning wood. In about ten minutes the sticks were consumed and the stones hot. They had previously folded up in small parcels of leaves pieces of beef, fish, ripe and unripe bananas, and the tops of the wild arum. These green parcels were laid in a layer between two layers of the hot stones, and the whole then covered up with earth, so that no smoke or steam could escape. In about a quarter of an hour, the whole was most deliciously cooked. The choice green parcels were now laid on a cloth of banana-leaves, and with a coconut-shell we drank the cool water of the running stream; and thus we enjoyed our rustic meal.—DARWIN *Naturalist's Voyage around the World*, ch. 18, p. 409. (A., 1898.)

594. CONQUESTS OF SCIENCE—*Warriors Accomplished Less than Peaceful Travelers.*—Altho in Columbus a capacity for exact observation was developed in manifold directions, notwithstanding his entire deficiency of all previous knowledge of natural history, and solely by contact with great natural phenomena, we must by no means assume a similar development in the rough and warlike body of the conquistadores. Europe owes to another and more peaceful class of travelers, and to a small number of distinguished men among municipal functionaries, ecclesiastics, and physicians, that which it has unquestionably acquired by the discovery of America, in the gradual enrichment of its knowledge regarding the character and composition of the atmosphere, and its action on the human organization; the distribution of climates on the declivities of the Cordilleras; the elevation of the line of perpetual snow in accordance with the different degrees of latitude in both hemispheres; the succession of volcanoes; the limitation of the circles of commotion in earthquakes; the laws of magnetism; the direction of oceanic currents, and the gradations of new animal and vegetable forms. The class of travelers to whom we have alluded, by residing in native Indian cities, some of which were situated twelve or thirteen thousand feet above the level of the sea, were enabled to observe with their own eyes, and, by a continued residence in those regions, to test and to combine the observations of others, to collect natural products, and to describe and transmit them to their European friends. It will suffice here to mention Gomara, Oviedo, Acosta, and Hernandez.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 273. (H., 1897.)

595. CONSCIENCE ACTIVE IN OPIUM-EATER—*Paralysis of Will—De Quincey.*—"The opium-eater loses none of his moral sensibilities or aspirations: he wishes and longs, as earnestly as ever, to realize what he believes possible and feels to be exacted by duty; but his intellectual apprehension of what is possible infinitely outruns his power, not of execution only, but of power to attempt. He lies under the weight of incubus and nightmare: he lies in sight of all that he would fain perform, just as a man forcibly confined to his bed by the mortal languor of a relaxing disease, who is compelled to witness injury or outrage offered to some object of his tenderest love—he curses the spells which chain him down from motion—he would lay down his life if he might but get up and walk; but he is powerless as an infant, and cannot even attempt to rise." [De Quincey, op. cit., pp. 136-138.]—CARPENTER *Mental Physiology*, bk. 2, ch. 17, p. 648. (A., 1900.)

596. CONSCIENCE, AGGREGATE, CONTROLLING INDIVIDUAL—*Laws Invariable—Combinations Subject to Change.*—As the reason and the conscience of the whole political community can interfere by the exercise of authority, so also may adequate remedies be found in the reason and the conscience of voluntary societies. The external conditions which tell upon the individual will are themselves very often nothing but conditions depending on the aggregate will of those around us; and if upon them, by any means, new motives can be brought to bear, then the whole of those external conditions may be changed. . . . It is often said that the conduct and condition of men are governed by invariable laws: and the conclusion is that the evils which arise by way of natural consequence out of the action of those laws are evils against which the struggles of the will are hopeless. But the facts on which this conclusion is founded are, as usual, inaccurately stated. The conditions of human life and conduct, like the conditions of all natural phenomena, are never governed by those separate and individual forces which alone are invariable, but always by combinations among those forces—which combinations are of endless variety, and of endless capability of change.—ARGYLL *Reign of Law*, ch. 7, p. 218. (Burt.)

597. CONSCIENCE, THE UNIVERSAL BELIEF OF MANKIND—*Formation of Character the Great Aim.*—The idea of "responsibility," on the other hand, which is entertained by mankind at large, rests upon the assumption, not only that each ego has a conscience which recognizes a distinction between right and wrong, and which (according to the training it has received) decides

what is right and what is wrong in each individual case, but also that he has a volitional power which enables him to intensify his sense of "duty" by fixing his attention upon it, and thus gives it a potency in determining his conduct which it might not have otherwise possessed. That this power is a part of the ego's "formed character," and that it can only be exerted within certain limits, is fully admitted on the doctrine I advocate; but the responsibility of the ego is shifted backwards to the share he has had in the formation of his character and in the determination of those limits. And here, again, the results of scientific investigation are in complete harmony with the precepts of the greatest of all religious teachers. For no one can study these with care without perceiving that Jesus and Paul addressed themselves rather to the formation of the character than to the laying down rules for conduct; that they endeavored rather to cultivate the dispositions which should lead to right action than to fix rigid lines of duty the enforcement of which under other circumstances might be not only unsuitable, but actually mischievous; and that they not only most fully recognized the power of each individual to direct the habitual course of his thoughts, to cherish his nobler affections, and to repress his sensual inclinations, but made the possession of that power the basis of the entire system of Christian morality.—CARPENTER *Mental Physiology*, pref., p. 46. (A., 1900.)

598. CONSCIOUSNESS AND ATOMIC MOTION DIFFERENT IN KIND—"Thus far our way is clear, but now comes my difficulty. Your atoms are individually without sensation, much more are they without intelligence. May I ask you, then, to try your hand upon this problem. Take your dead hydrogen atoms, your dead oxygen atoms, your dead carbon atoms, your dead nitrogen atoms, your dead phosphorus atoms, and all the other atoms, dead as grains of shot, of which the brain is formed. Imagine them separate and sensationless; observe them running together and forming all imaginable combinations. This, as a purely mechanical process, is seeable by the mind. But can you see, or dream, or in any way imagine, how out of that mechanical act, and from these individually dead atoms, sensation, thought, and emotion are to rise? Are you likely to extract Homer out of the rattling of dice, or the differential calculus out of the clash of billiard-balls? . . . I can follow a particle of musk until it reaches the olfactory nerve; I can follow the waves of sound until their tremors reach the water of the labyrinth, and set the otoliths and Corti's fibers in motion; I can also visualize the waves of ether as they cross the eye and hit the retina. Nay, more. I am able to pursue to the central organ the motion thus imparted at the periphery, and to see in idea the very molecules of the brain thrown into tremors. My insight is not baffled by these physical processes. What baffles and bewilders me is the notion that from those physical tremors things so utterly incongruous with them as sensation, thought, and emotion can be derived." [Supposed quotation from Bishop Butler.] —TYNDALL *Fragments of Science (the Belfast Address)*, vol. ii, ch. 9, p. 167. (A., 1900.)

599. CONSCIOUSNESS AN UNRESTING STREAM—*Not an Assemblage of Molded Forms—Mind Not to Be Measured Off into Departments.*—The traditional psychology talks like one who should say a river consists of nothing but pailsful, spoonsful, quartpotsful, barrelsful, and other molded forms of water. Even were the pails and the pots all actually standing in the stream, still between them the free water would continue to flow. It is just this free water of consciousness that psychologists resolutely overlook. Every definite image in the mind is steeped and dyed in the free water that flows round it. With it goes the sense of its relations, near and remote, the dying echo of whence it came to us, the dawning sense of whither it is to lead. The significance, the value, of the image is all in this halo or penumbra that surrounds and escorts it—or rather that is fused into one with it and has become bone of its bone and flesh of its flesh; leaving it, it is true, an image of the same thing it was before, but making it an image of that thing newly taken and freshly understood.—JAMES *Psychology*, vol. i, ch. 9, p. 255. (H. H. & Co., 1899.)

600. CONSCIOUSNESS AS A STAGE—*Ideas as Actors, Appearing and Disappearing—Comparison Misleading—Unconscious Idea Also Unknown—Same Idea Never Returns.*—Nothing is more natural than to think of consciousness as a kind of stage upon which our ideas are the actors, appearing, withdrawing behind the scenes, and coming on again when their cue is given. . . . Nevertheless this comparison of consciousness to a stage is entirely misleading. The stage remains when the actors have left it; it has an existence of its own, which is not dependent upon them. But consciousness does not continue to exist when the processes of which we are conscious have passed away; it changes constantly with their changes, and is not anything which can be distinguished from them. When the actor has left the stage, we know that he is somewhere else. But when an idea has disappeared from consciousness we know nothing at all about it. Strictly speaking, it is not correct to say that it subsequently returns. For the same idea never returns. A subsequent idea may be more or less similar to an earlier one; but it is probably never exactly the same.—WUNDT *Psychology*, lect. 16, p. 235. (Son. & Co., 1896.)

601. CONSCIOUSNESS, CONTINUITY OF—*Individuality Endures through All Change—Sleep Does Not Sunder.*—When Paul and Peter wake up in the same bed, and recognize that they have been asleep, each one of them mentally reaches back and makes connection with but one of the two streams of thought which were broken by the sleeping hours. As the current of an electrode buried in the ground unerringly finds its way to its own similarly buried mate, across no matter how much intervening earth, so Peter's present instantly finds out Peter's past, and never by mistake knits itself on to that of Paul. Paul's thought in turn is as little liable to go astray. The past thought of Peter is appropriated by the present Peter alone. He may have a knowledge, and a correct one, too, of what Paul's last drowsy states of mind were as he sank into sleep, but it is an entirely different sort of knowledge from that which he has of his own last states. He remembers his own states, whilst he only conceives Paul's. . . . This community of self is what the time-gap cannot break in twain, and is why a present thought, altho not ignorant of the time-gap, can still regard itself as continuous with certain chosen portions of the past. . . . A "river" or a "stream" are the metaphors by which it is most naturally described.—JAMES *Psychology*, vol. i, ch. 9, p. 238. (H. H. & Co., 1890.)

602. CONSCIOUSNESS DEAD TO EVER-PRESENT FACT—*Sound Always in the Ear Never Heard.*—It is a law of nervous stimulation that a continued activity of any structure results in less and less psychic result, and that when a stimulus is always at work it ceases in time to have any appreciable effect. The common illustration of this law is drawn from the region of sound. A constant noise, as of a mill, ceases to produce any conscious sensation. This fact, it is plain, may easily become the commencement of an illusion. Not only may we mistake a measure of noise for perfect silence, we may misconceive the real nature of external circumstances by overlooking some continuous impression.—SULLY *Illusions*, ch. 4, p. 56. (A., 1897.)

603. CONSCIOUSNESS DEPENDS ON CONTRAST—*An Unvarying Sensation Is Unperceived—Incessant Ticking of Clock.*—It is a familiar observation that an unvarying action on any of our senses has, when long continued, the same effect as no action at all. We are not conscious of the pressure of the atmosphere. An even temperature, such as that enjoyed by the fishes in the tropical seas, leaves the mind an entire blank as regards heat and cold. The feeling of warmth is not an absolute, independent, or self-sustaining condition of mind, but the result of a transition from cold; the sensation of light supposes a transition from darkness or shade, or from a less degree of illumination to a greater. To use a familiar illustration, a watchmaker is not conscious of the unintermitted ticking of his clocks; but were they all suddenly stopped, he would at once become aware of the blank.—BAIN *Mind and Body*, ch. 4, p. 12. (Hum., 1880.)

604. ——— ——— *Enjoyment by Transition—Advantages of Wealth.*—People are generally aware that the first shock of transition from sickness to health, from poverty to abundance, from ignorance to insight, is the most intense; and that, as the memory of the previous condition fades away, so does the liveliness of the enjoyment of the change. Shakespeare speaks of the miser's looking but rarely at his hoards for fear of "blunting the fine point of seldom pleasure"; and makes the versatile Prince Hal say that

"If all the year were playing holidays,
To sport would be as tedious as to work."

The blessings of leisure, retirement, and rest are pleasant only by contrast to previous toil and excitement. The incessant demand for novelty and change, for constant advances in wealth, in knowledge, in the arrangements of things about us—attest the existence and the power of the law of relativity in all the provisions for enjoyment. It is a law that greatly neutralizes one part of the advantages of superior fortune, the sense of the superiority itself, but leaves another part untouched—namely, the range, variety, and alternation of pleasures.—BAIN *Mind and Body*, ch. 4, p. 12. (Hum., 1880.)

605. CONSCIOUSNESS NOT A PRODUCT OF PHYSICAL FORCES—*Nature of the Soul Still a Mystery (Eccl. iii, 21).*—Whence came the soul we no more know than we know whence came the universe. The primal origin of consciousness is hidden in the depths of the bygone eternity. That it cannot possibly be the product of any cunning arrangement of material particles is demonstrated beyond peradventure by what we now know of the correlation of physical forces.—FISKE *Destiny of Man*, ch. 5, p. 42. (H. M. & Co., 1900.)

606. CONSCIOUSNESS NOT EXPLICABLE BY MECHANICAL OR MOLECULAR THEORY—We may even affirm that the brain of man—the organ of his reason—without which he can neither think nor feel, is also an assemblage of molecules, acting and reacting according to law. Here, however, the methods pursued in mechanical science come to an end; and if asked to deduce from the physical interaction of the brain molecules the least of the phenomena of sensation or thought, I acknowledge my helplessness. The association of both with the matter of the brain may be as certain as the association of light with the rising of the sun. But whereas in the latter case we have unbroken mechanical connection between the sun and our organs, in the former

case logical continuity disappears. Between molecular mechanics and consciousness is interposed a fissure over which the ladder of physical reasoning is incompetent to carry us.—TYNDALL *Fragments of Science*, vol. ii, ch. 15, p. 388. (A., 1900.)

607. CONSCIOUSNESS PERSISTS IN SLEEP—*Waking Ideas Control—"A Dream Cometh through the Multitude of Business" (Eccl. v, 3).*—Our dream-operations have been found to have a much closer connection with our waking experiences than could be supposed on a superficial view. The materials of our dreams are seen, when closely examined, to be drawn from our waking experience. Our waking consciousness acts in numberless ways on our dreams, and these again in unsuspected ways influence our waking mental life. Not only so, it is found that the quaint chaotic play of images in dreams illustrates mental processes and laws which are distinctly observable in waking thought. Thus, for example, the apparent objective reality of these visions has been accounted for, without the need of resorting to any supernatural agency, in the light of a vast assemblage of facts gathered from the byways, so to speak, of waking mental life.—SULLY *Illusions*, ch. 7, p. 130. (A., 1897.)

608. CONSCIOUSNESS, POWER OF—*Influences the Bodily Life.*—The particulars of the distribution of consciousness, so far as we know them, point to its being efficacious. It is very generally admitted, tho the point would be hard to prove, that consciousness grows the more complex and intense the higher we rise in the animal kingdom. That of a man must exceed that of an oyster. From this point of view it seems an organ, superadded to the other organs which maintain the animal in the struggle for existence; and the presumption, of course, is that it helps him in some way in the struggle, just as they do. But it cannot help him without being in some way efficacious and influencing the course of his bodily history. If now it could be shown in what way consciousness *might* help him, and if, moreover, the defects of his other organs . . . are such as to make them need just the kind of help that consciousness would bring provided it *were* efficacious; why, then the plausible inference would be that it came just *because* of its efficacy—in other words, its efficacy would be inductively proved.—JAMES *Psychology*, vol. i, ch. 5, p. 138. (H. H. & Co., 1899.)

609. CONSCIOUSNESS REPUDIATES MATERIALISM—*The Soul Not a Combination of Atoms.*—To be sure, we cannot, no, we cannot be satisfied with that practical outcome of psychology, with those conclusions about the final character of personality and freedom [as mere psychophysical processes " for nobody, for no end, and with no value "], about history and logic and ethics, about man and the universe. Every fiber in us revolts, every value in our real life rejects such a construction. We do not feel ourselves such conglomerates of psychophysical elements, and the men whom we admire and condemn, love and hate, are for us not identical with those combinations of psychical atoms which pull and push one another after psychological laws. We do not mean, with our responsibility and with our freedom in the moral world, that our consciousness is the passive spectator of psychological processes which go on causally determined by laws, satisfied that some of the causes are inside our skull, and not outside. The child is to us in real life no vegetable which can be raised like tomatoes, and the criminal is no weed which does not feel that it destroys the garden.—MÜNSTERBERG *Psychology and Life*, p. 15. (H. M. & Co., 1899.)

610. CONSCIOUSNESS SUSPENDED—*Effect of a Lightning-stroke.*—On June 30, 1788, a soldier in the neighborhood of Mannheim, being overtaken by rain, placed himself under a tree, beneath which a woman had previously taken shelter. He looked upwards to see whether the branches were thick enough to afford the required protection, and, in doing so, was struck by lightning, and fell senseless to the earth. The woman at his side experienced the shock in her foot, but was not struck down. Some hours afterwards the man revived, but remembered nothing about what had occurred, save the fact of his looking up at the branches. This was his last act of consciousness, and he passed from the conscious to the unconscious condition without pain.—TYNDALL *Fragments of Science*, vol. i, ch. 21, p. 442. (A., 1900.)

611. CONSERVATION OF ENERGY—*Heat, Light, Magnetism, Electricity, and Motion Convertible.*—The phrase "conservation of energy" does not cover the whole subject that it is intended to cover. It involves the correlation of energy, or, as it has been called in earlier times, the correlation of forces, as well as the transmutation of energy, by which is meant a change from one form to another. For instance, heat as an energy may be converted into another form called electricity, and this in turn may be reconverted into heat. This process is called transmutation. The energy, as such, representing a definite amount of work, remains the same in both cases. Heat, light, magnetism, electricity, are all different modes or forms of energy working through motion; the fact that they are interchangeable is their "correlation"; the fact that the amount of energy remains the same through all changes is its "conservation." Energy is a constant quantity.—ELISHA GRAY *Nature's Miracles*, vol. ii, ch. 1, p. 2. (F. H. & H., 1900.)

612. ——— ——— *Heat Stored in Lime —Given Back in "Slacking."*—Lime is produced from ordinary limestone by burning it in kilns, where it is subjected to a heat of a certain temperature for a number of hours. The heat drives off the carbon dioxid, which, as we have seen, has taken away from each molecule of the compound all of the carbon and two atoms of the oxygen, while all of the calcium is retained with one atom of oxygen, leaving ordinary lime. Lime, then, is simply oxid of calcium. As all know, it is used almost exclusively for making mortar for building purposes. In order to do this we have to put it through the process of "slacking," by pouring water upon it, and here another chemical change takes place. The water unites with the lime, when immediately the heat that was expended in throwing off the carbon dioxid and was stored in the lime as energy is now given up again in the form of heat. When a considerable bulk of lime is slacked very rapidly the heat that is given off is so great that it will produce combustion. Here is a beautiful illustration of what has been erroneously called "latent heat." It is "heat stored as potential energy" that is released by the combination of lime with water.—ELISHA GRAY *Nature's Miracles*, vol. i, ch. 2, p. 17. (F. H. & H., 1900.)

613. ——— ——— *The Sun's Heat the Source of Terrestrial Motion.*—The law of the conservation of energy implies that in any limited system of bodies, whether a steam-engine or the solar system, no change can occur in the total amount of the energy it contains unless fresh energy comes to it from without, or is lost by transmission to bodies outside it. But as, in the case of the sun, some heat is certainly lost by radiation into space unless an equal amount comes in from the stellar universe, the system must be cooling, and in sufficient time would lose all its heat, and therefore much of its energy. The chief use of the principle is to teach us what becomes of force expended without any apparent result, as when a ball falls to the ground and comes to rest. We now know that the energy of the falling ball is converted into heat, which, if it could be all preserved and utilized, would again raise the ball to the height from which it fell. It also enables us to trace most of the energy around us, whether of wind, or water, or of living animals, to the heat and light of the sun. Wind is caused by inequalities of the sun's heat on the earth; all water-power is due to evaporation by the sun's heat, which thus transfers the water from the ocean surface to the mountains, producing rivers; solar heat alone gives power to plants to absorb carbonic acid and build up their tissues, and the energy thus locked up is again liberated during the muscular action of the animals which have fed directly or indirectly on the plants.—WALLACE *The Wonderful Century*, ch. 7, p. 52. (D. M. & Co., 1899.)

614. ——— ——— *Why Does the Sun Not Burn Out?—A Problem Yet Unsolved.*—Thought has, in many directions, been profoundly modified by Mayer's and Joule's discovery, in 1842, of the equivalence between heat and motion. Its corollary was the grand idea of the "conservation of energy," now one of the cardinal principles of science. This means that, under the ordinary circumstances of observation, the old maxim *ex nihilo nihil fit* applies to force as well as to matter. The supplies of heat, light, electricity, must be kept up, or the stream will cease to flow. The question of the maintenance of the sun's heat was thus inevitably raised; and with the question of maintenance that of origin is indissolubly connected.

Dr. Julius Robert Mayer, a physician residing at Heilbronn, . . . showed that if the sun were a body either simply cooling or in a state of combustion, it must long since have "gone out." Had an equal mass of coal been set alight, four or five centuries after the building of the Pyramid of Cheops, and kept burning at such a rate as to supply solar light and heat during the interim, only a few cinders would now remain in lieu of our undiminished glorious orb.—CLERKE *History of Astronomy*, pt. ii, ch. 9, p. 376. (Bl., 1893.)

615. CONSISTENCY OF PROGRESS —*Mind Required to Construe the World—What to Construct It?—Design Transferred from Phenomena to Law.*—As the doctrine of natural selection out of an endless diversity of "aimless" variations fails to account for that general consistency of the advance along definite lines of progress which is manifested in the history of evolution, . . . it leaves untouched the evidence of design in the original scheme of the organized creation; while it transfers the idea of that design from the particular to the general, making all the special cases of adaptation the foreknown results of the adoption of that general order which we call law. As Dr. Martineau has pertinently asked: "If it takes mind to construe the world, how can it require the negation of mind to constitute it?" Science, being the intellectual interpretation of Nature, cannot possibly disprove its origin in mind; and, if rightly pursued, leads us only to a higher comprehension of the "bright designs," a more assured recognition of the working of the "sovereign will," of its divine author.—CARPENTER *Nature and Man*, lect. 15, p. 463. (A., 1889.)

616. CONSTANCY, IMPORTANCE OF —*History of Drinking Water a Determining Element.*—It is generally only possible to form an accurate judgment of a water from watching its history—that is, not from one examination only, but from a series of observations. A water yielding a steady standard of bacterial contents is a much more satisfactory water, from every point of view,

than one which is unstable, one month possessing 500 bacteria per c. c. and another month 5,000.—NEWMAN *Bacteria*, ch. 2, p. 51. (G. P. P., 1899.)

617. CONSTANCY OF LAWS OF NATURE—*Adapts Universe for Rational Beings.*—Unless the laws of Nature were constant, in so far as our experience extends, we could have no certain basis either for science or for practical life. All would be capricious and uncertain, and we could calculate on nothing. Law thus adapts the universe to be the residence of rational beings, and nothing else could.—DAWSON *Facts and Fancies in Modern Science*, lect. 1, p. 39. (A. B. P. S.)

618. ——— ——— *Altitude Determined by Boiling-point.*—As we ascend a mountain, the pressure of the atmosphere above us diminishes, and the boiling-point is correspondingly lowered. On an August morning in 1859 I found the temperature of boiling water on the summit of Mont Blanc to be 184.95° F.; that is, about twenty-seven degrees lower than the boiling-point at the sea-level. On August 3, 1858, the temperature of boiling water on the summit of the Finsteraarhorn was 187° F. On August 10, 1858, the boiling-point on the summit of Monte Rosa was 184.92° F. The boiling-point on Monte Rosa is shown by these observations to be almost the same as it was found to be on Mont Blanc, tho the latter exceeds the former in height by 500 feet. The fluctuations of the barometer are, however, quite sufficient to account for this anomaly. The lowering of the boiling-point is about 1° F. for every 590 feet of elevation; and from the temperature at which water boils we may approximately infer the height.—TYNDALL *Heat a Mode of Motion*, lect. 6, p. 100. (A., 1900.)

619. CONSTANCY OF VISION—*Ancient Same as Modern—Six or Seven Stars Seen in the Pleiades.*—However diversified the power of vision may be in different persons, there is nevertheless a certain average of organic capacity, which was the same among former generations, as, for instance, the Greeks and Romans, as at the present day. The Pleiades prove that several thousand years ago, even as now, stars which astronomers regard as of the seventh magnitude were invisible to the naked eye of average visual power. The group of the Pleiades consists of one star of the third magnitude, Alcyone; of two of the fourth, Electra and Atlas; of three of the fifth, Merope, Maia, and Taygeta; of two between the sixth and the seventh magnitudes, Pleione and Celæno; of one between the seventh and the eighth, Asterope; and of many very minute telescopic stars. I make use of the nomenclature and order of succession at present adopted, as the same names were among the ancients in part applied to other stars. The six first-named stars of the third, fourth, and fifth magnitudes were the only ones which could be readily distinguished. Of these Ovid says (Fast., iv, 170):

"Quæ septem dici, sex tamen esse solent."
[Which are called seven, but are usually seen as six.]

One of the daughters of Atlas, Merope, the only one who was wedded to a mortal, was said to have veiled herself for very shame, or even to have wholly disappeared. This is probably the star of about the seventh magnitude which we call Celæno; for Hipparchus, in his commentary on Aratus, observes that on clear moonless nights seven stars may actually be seen. Celæno, therefore, must have been seen, for Pleione, which is of equal brightness, is too near to Atlas, a star of the fourth magnitude.—HUMBOLDT *Cosmos*, vol. iii, p. 48. (H., 1897.)

620. ——— ——— *The Same Constellations Recognized by Rudest Nations.*—Amid the innumerable multitude of great and small stars, which seem scattered, as it were by chance, throughout the vault of heaven, even the rudest nations separate single (and almost invariably the same) groups, among which certain bright stars catch the observer's eye, either by their proximity to each other, their juxtaposition, or, in some cases, by a kind of isolation. This fact has been confirmed by recent and careful examinations of several of the languages of so-called savage tribes. Such groups excite a vague sense of the mutual relation of parts, and have thus led to their receiving names which, altho varying among different races, were generally derived from organic terrestrial objects. Amid the forms with which fancy animated the waste and silent vault of heaven, the earliest groups thus distinguished were the seven-starred Pleiades, the seven stars of the Great Bear, subsequently (on account of the repetition of the same form) the constellation of the Lesser Bear, the belt of Orion (Jacob's staff), Cassiopeia, the Swan, the Scorpion, the Southern Cross (owing to the striking difference in its direction before and after its culmination), the Southern Crown, the Feet of the Centaur (the Twins, as it were, of the southern hemisphere), etc.—HUMBOLDT *Cosmos*, vol. iii, p. 117. (H., 1897.)

621. CONSTITUENTS OF THE SUN—*Rays of Nucleus and Photosphere Conflict—Fraunhofer's Lines.*—The sun, according to Kirchhoff, consists of a central orb, molten or solid, of exceeding brightness, which emits all kinds of rays, and would therefore, if unhindered, give a continuous spectrum. The radiation from the nucleus, however, has to pass through the photosphere, and this vaporous envelope cuts off those particular rays of the nucleus which it can itself emit—the lines of Fraunhofer marking the position of the failing rays. Could we abolish the central orb, and obtain

the spectrum of the gaseous envelope alone, we should obtain a striped spectrum, each bright band of which would coincide with one of Fraunhofer's dark lines. These lines, therefore, are spaces of relative, not of absolute, darkness; upon them the rays of the absorbent photosphere fall; but these, not being sufficiently intense to make good the light intercepted, the spaces which they illuminate are dark, in comparison to the general brilliancy of the spectrum.—TYNDALL *Heat a Mode of Motion,* lect. 17, p. 512. (A., 1900.)

622. CONTAGION, SPREAD OF, AMONG SILKWORMS—*Care Necessary to Exclude Germs—One Infected Individual Will Poison Many.*—To protect the worms from contagion it is necessary to raise them at a distance from where infection has originated, in separate localities, perfectly adapted, that have been cleansed with the greatest care, and after all the apparatus has been most energetically washed to remove all the dust and débris of any preceding culture. And besides, it is necessary to take the most minute precautions not to introduce the germ of the malady into the room, especially no germ produced by a contemporaneous culture, since the contagion is infinitely more easy with the fresh dust than with that which is dry or old. Just one infected worm trailing its body and its dejecta over the leaves can poison a considerable number of healthy worms.—PASTEUR *Études sur la Maladie des Vers à Soie,* p. 64. (Translated for *Scientific Side-Lights.)*

623. CONTAMINATION, ARTIFICIAL—*Oysters Fattened on Sewage.*—It is four or five years since Professor Conn startled the medical world by tracing an epidemic of typhoid fever to the consumption of some uncooked oysters. Almost at the same time Sir William Broadbent published in the *British Medical Journal* a series of cases occurring in his practise which illustrated the same channel of infection. Since then a number of similar items of evidence to the same effect have cropped up. . . . The mode of infection of oysters by pathogenic bacteria is briefly as follows: The sewage of certain coast towns is passed untreated out to sea. At or near the outfall, oyster-beds are laid down for the purpose of fattening oysters. Thus they become contaminated with saprophytic and pathogenic germs contained in the sewage.—NEWMAN *Bacteria,* ch. 6, p. 229. (G. P. P., 1899.)

624. CONTEMPLATION, INVESTIGATION, EXPERIMENT—*The Three Stages in Knowledge of Phenomena.*—To the mere contemplation of Nature, to the observation of the phenomena accidentally presented to the eye in the terrestrial and celestial regions of space, succeeds investigation into the actual, an estimate by the measurement of magnitudes and the duration of motion. The earliest epoch of such a species of natural observation, altho principally limited to organic substances, was the age of Aristotle. There remains a third and higher stage in the progressive advancement of the knowledge of physical phenomena, which embraces an investigation into natural forces, and the powers by which these forces are enabled to act, in order to be able to bring the substances liberated into new combinations. The means by which this liberation is effected are experiments, by which phenomena may be called forth at will. The last-named stage of the process of knowledge, which was almost wholly disregarded in antiquity, was raised by the Arabs to a high degree of development.—HUMBOLDT *Cosmos,* vol. ii, pt. ii, p. 209. (H., 1897.)

625. CONTEMPLATION OF NATURE—*A Joy to Man—Its Silent Influence.*—In reflecting upon the different degrees of enjoyment presented to us in the contemplation of Nature, we find that the first place must be assigned to a sensation which is wholly independent of an intimate acquaintance with the physical phenomena presented to our view, or of the peculiar character of the region surrounding us. In the uniform plain bounded only by a distant horizon, where the lowly heather, the cistus, or waving grasses deck the soil; on the ocean shore, where the waves, softly rippling over the beach, leave a track, green with the weeds of the sea; everywhere, the mind is penetrated by the same sense of the grandeur and vast expanse of Nature, revealing to the soul, by a mysterious inspiration, the existence of laws that regulate the forces of the universe. Mere communion with Nature, mere contact with the free air, exercise a soothing yet strengthening influence on the wearied spirit, calm the storm of passion, and soften the heart when shaken by sorrow to its inmost depths. Everywhere, in every region of the globe, in every stage of intellectual culture, the same sources of enjoyment are alike vouchsafed to man.—HUMBOLDT *Cosmos,* vol. i, int., p. 25. (H., 1897.)

626. CONTEMPT OF SCHOLASTICS FOR SCIENCE—*Medieval Problems Concerned the Future World.*—The men of the Middle Ages, in fact, endeavored on the one hand to develop the laws of the universe a priori out of their own consciousness, while many of them were so occupied with the concerns of a future world that they looked with a lofty scorn on all things pertaining to this one. Speaking of the natural philosophers of his time, Eusebius says, "It is not through ignorance of the things admired by them, but through contempt of their useless labor, that we think little of these matters, turning our souls to the exercise of better things." So also Lactantius—"To search for the causes of things; to inquire whether the sun be as large as he seems; whether the moon is convex or concave; whether the stars are fixed in the sky, or float freely in the air; of

what size and of what material are the heavens; whether they be at rest or in motion; what is the magnitude of the earth; on what foundations is it suspended or balanced—to dispute and conjecture upon such matters is just as if we chose to discuss what we think of a city in a remote country, of which we never heard but the name."—TYNDALL *Lectures on Light,* lect. 1, p. 13. (A., 1898.)

627. CONTINENTS AND OCEANS PERSISTENT — *The Same General Formations from Geologic Times.*—We now know for certain that the sands and clays washed off the land—whether by the action of ice or river-waters on its surface, or by the wearing away of its margin by the waves of the sea—sink to the sea-bottom long before they reach the deeper abysses; not the least trace of such sediments having been anywhere found at a distance from the continental platforms. And thus the study of the deposits on the oceanic sea-bed has fully confirmed the conclusion drawn from the present configuration of the earth's surface, as to the general persistence of those original inequalities which have served as the bases of the existing continents, and the floors of the great ocean-basins.

In the masterly lecture on "Geographical Evolution," . . . given by Professor Geikie before the Royal Geographical Society, . . . he thus sums up:

"From all this evidence we may legitimately conclude that the present land of the globe, tho composed in great measure of marine formations, has never lain under the deep sea, but that its site must always have been near land. Even its thick marine limestones are the deposits of comparatively shallow water. Whether or not any trace of aboriginal land may now be discoverable, the characters of the most unequivocally marine formations bear emphatic testimony to the proximity of a terrestrial surface. The present continental ridges have probably always existed in some form; and as a corollary we may infer that the present deep ocean-basins likewise date from the remotest geological antiquity."—CARPENTER *Nature and Man,* lect. 11, p. 332. (A., 1889.)

628. CONTINENTS PERPETUALLY WASHED INTO THE SEA—The disintegrated materials, produced by chemical and mechanical actions of the atmospheric waters upon rock-masses, are by floods, rivers, and glaciers gradually transported from higher to lower levels; and sooner or later every fragment, when it has once been separated from a mountain-top, must reach the ocean, where these materials are accumulated and arranged to form new rocks.—JUDD *Volcanoes,* ch. 10, p. 284. (A., 1899.)

629. CONTINENTS, RELATIVE HEIGHT OF—*The "Sea-level" a Fluctuating Line.*—The existing land-surfaces of the globe are composed most frequently of marine strata. There are apparently only two ways in which this phenomenon can be accounted for, and these explanations come to much the same thing. Either the general level of the ocean has fallen, or wide areas of the sea-floor have been pushed up from below and converted into dry land. Both changes appear to have taken place. The bed of the sea has sunk from time to time to greater and greater depths, and has thus tended to draw the water away from the surface of what are now continental areas. But if the earth's crust under the ocean has subsided, it has also been elevated within what are now dry lands again and again.—GEIKIE *Earth Sculpture,* ch. 1, p. 12. (G. P. P., 1898.)

630. CONTINENTS SUBMERGED AT VARIOUS EPOCHS—*"The Earth Standing Out of the Water and in the Water."*—The extensive geographical range of the derivative rocks, most of which are of marine origin, must convince us that the greater portion of our continental areas has been under water. It is not to be understood, however, that all the land-surfaces occupied by sedimentary strata have been submerged at one and the same time. On the contrary, the several geological systems have been accumulated at widely different periods.—GEIKIE *Earth Sculpture,* ch. 1, p. 12. (G. P. P., 1898.)

631. CONTINUITY OF NATURE—*A Universe without Law, a Universe Deranged.*—Probably the most satisfactory way to secure for oneself a just appreciation of the principle of continuity is to try to conceive the universe without it. The opposit of a continuous universe would be a discontinuous universe, an incoherent and irrelevant universe—as irrelevant in all its ways of doing things as an irrelevant person. In effect, to withdraw continuity from the universe would be the same as to withdraw reason from an individual. The universe would run deranged.—DRUMMOND *Natural Law in the Spiritual World,* int., p. 34. (H. Al.)

632. CONTRACTION OF BULK MAY SUSTAIN HEAT OF SUN—*Gravity the Cause of Heat.*—If, now, there is no present manifestation of force sufficient to cover the expenditure of the sun's heat, the sun must originally have had a store of heat which it gradually gives out. But whence this store? We know that the cosmical forces alone could have produced it. And here the hypothesis, previously discussed as to the origin of the sun, comes to our aid. If the mass of the sun had been once diffused in cosmical space, and had then been condensed—that is, had fallen together under the influence of celestial gravity—if then the resultant motion had been destroyed by friction and impact, with the production of heat, the new world produced by such condensation must

have acquired a store of heat not only of considerable, but even of colossal, magnitude.—HELMHOLTZ *Popular Lectures,* lect. 4, p. 181. (L. G. & Co., 1898.)

633. ——— ——— *This Involves Final Extinction.*—In the very act of parting with heat, the sun develops a fresh stock. His radiations, in short, are the direct result of shrinkage through cooling. A diminution of the solar diameter by 380 feet yearly would just suffice to cover the present rate of emission, and would for ages remain imperceptible with our means of observation, since, after the lapse of 6,000 years, the lessening of angular size would scarcely amount to one second. But the process, tho not terminated, is strictly a terminable one. In less than five million years the sun will have contracted to half its present bulk. In seven million more, it will be as dense as the earth. It is difficult to believe that it will then be a luminous body. Nor can an unlimited past duration be admitted. Helmholtz considered that radiation might have gone on with its actual intensity for twenty-two, Langley allows only eighteen, million years. The period can scarcely be stretched, by the most generous allowances, to double the latter figure. But this is far from meeting the demands of geologists and biologists.—CLERKE *History of Astronomy,* pt. ii, ch. 9, p. 379. (Bl., 1893.)

634. CONTRADICTION, SEEMING, IN REFLECTION OF LIGHT—*White Light May Come from a Black Object.*—The light which falls upon a body is divided into two portions, one of which is reflected from the surface of the body; and this is of the same color as the incident light. If the incident light be white the superficially reflected light will also be white. Solar light, for example, reflected from the surface of even a black body, is white. The blackest camphine smoke in a dark room through which a sunbeam passes from an aperture in the window-shutter renders the track of the beam white, by the light scattered from the surfaces of the soot-particles. The moon appears to us as if

"Clothed in white samite, mystic, wonderful";

but were she covered with the blackest velvet she would still hang in the heavens as a white orb, shining upon our world substantially as she does now.—TYNDALL *Lectures on Light,* lect. 1, p. 33. (A., 1898.)

635. CONTRAST, IMPRESSIVE—*Forest and Steppe.*—From the rich luxuriance of organic life the astonished traveler [to the steppes of South America] suddenly finds himself on the dreary margin of a treeless waste. Nor hill nor cliff rears its head, like an island in the ocean, above the boundless plain: only here and there broken strata of floetz, extending over a surface of more than three thousand English square miles, appear sensibly higher than the surrounding district. The natives term them banks, as if the spirit of language would convey some record of that ancient condition of the world when these elevations formed the shoals, and the steppes themselves the bottom, of some vast inland sea.—HUMBOLDT *Views of Nature,* p. 1. (Bell, 1896.)

636. CONTRAST OF GIVING AND WITHHOLDING—*Mountain Lake with Flowing Stream—Bitter Waters with No Outlet.*—The waters of Lake Tahoe overflow through the Truckee cañon and form a bright, swift-flowing stream, which finds its way to Pyramid and Winnemucca lakes, situated 2,400 feet lower, in the desert valleys to the north. The waters when starting on their troubled journey are as pure and limpid as the melting snows of mountain valleys can furnish, . . . but the lakes into which they flow, and of which they form almost the sole supply, are alkaline and saline owing to long concentration. An example of an isolated drainage system is here furnished, embracing the cool summits of lofty mountains where the moisture of the atmosphere is condensed; a mountain reservoir where the waters are stored; a swift, clear stream formed by the overflow of the reservoir; and the bitter lakes where the stream empties and from which there is no escape except by evaporation.—RUSSELL *Lakes of North America,* ch. 4, p. 64. (G. & Co., 1895.)

637. CONTRAST OF HEAT AND COLD IN SOUTH AFRICA — *Solar Radiation — Wide Difference between Sunrise and Midday.*—Dr. Livingstone, in his "Travels in South Africa," has given some striking examples of the difference in nocturnal chilling when the air is dry and when it is laden with moisture. Thus he finds in South Central Africa during the month of June, "the thermometer early in the mornings at from 42° to 52°; at noon, 94° to 96°," or a mean difference of 48° between sunrise and midday. The range would probably have been found still greater had not the thermometer been placed in the shade of his tent, which was pitched under the thickest tree he could find. He adds, moreover, "the sensation of cold after the heat of the day was very keen. The Balonda at this season never leave their fires till nine or ten in the morning. As the cold was so great here, it was probably frosty at Linyanti; I therefore feared to expose my young trees there."—TYNDALL *Heat a Mode of Motion,* lect. 13, p. 387. (A., 1900.)

638. CONTRAST OF REFLECTED AND TRANSMITTED LIGHT—*Sunrise on Mt. Blanc.*—The sunrise from the summit [of Mt. Blanc] was singularly magnificent. The snow on the shaded flanks of the mountain was of a pure blue, being illuminated solely by the reflected light of the sky; the summit of the mountain, on the contrary,

was crimson, being illuminated by transmitted light. The contrast of both was finer than I can describe.—TYNDALL *Hours of Exercise in the Alps*, ch. 4, p. 57. (A., 1898.)

639. CONTRAST OF STORM-SWEPT MOUNTAIN AND SUNLIT VALLEY—*Pike's Peak in July—Waiting for Solar Eclipse under Difficulties.*—The snow entered [the tent] with the wind and lay in a deep drift on the pillow, when I woke after a brief sleep toward morning, and, looking out on the gray dawn, found that the snow had turned to hail, which was rattling sharply on the rocks with an accompaniment of thunder, which seemed to roll from all parts of the horizon. The snow lay thick, and the sheets of hail were like a wall, shutting out the sight of everything a few rods off, and this was in July [1878]! Hail, rain, sleet, snow, fog, and every form of bad weather continued for a week on the summit, while it was almost always clear below. It was often a remarkable sight to go to the edge and look down. The expanse of "the plains," which stretched eastward to a horizon line over a hundred miles distant, would be in bright sunshine beneath, while the hail was all around and above us; and the light coming up instead of down gave singular effects when the clouds parted below, the plains seeming at such times to be opalescent with luminous yellow and green, as tho the lower world were translucent and the sun were beneath it and shining up through.—LANGLEY *New Astronomy*, ch. 2, p. 54. (H. M. & Co.)

640. CONTRAST OF TEMPERATE AND TROPICAL VEGETATION—*Temperate Lands within the Tropics.*—The extraordinary height to which not only individual mountains but even whole districts rise in tropical regions, and the consequent cold of such elevations, affords the inhabitant of the tropics a singular spectacle. For besides his own palms and bananas, he is surrounded by those vegetable forms which would seem to belong solely to northern latitudes. Cypresses, pines, and oaks, barberry shrubs and alders (nearly allied to our own species), cover the mountain plains of southern Mexico and the chain of the Andes at the equator. Thus Nature has permitted the native of the torrid zone to behold all the vegetable forms of the earth without quitting his own clime, even as are revealed to him the luminous worlds which spangle the firmament from pole to pole.—HUMBOLDT *Views of Nature*, p. 231. (Bell, 1896.)

641. CONTRAST WITH ALL KNOWN EARTHLY CONDITIONS—*Endless Day and Endless Night on Mercury.*—And after long and patient watching, the conclusion was at last reached that Mercury turns on his axis in the same time needed to complete a revolution in his orbit. One of his hemispheres, then, is always averted from the sun, as one of the moon's hemispheres from the earth, while the other never shifts from beneath his torrid rays. The "librations," however, of Mercury are on a larger scale than those of the moon, because he travels in a more eccentric path. The temporary inequalities arising between his "even pacing" on an axis and his alternately accelerated and retarded elliptical movement occasion, in fact, an oscillation to and fro of the boundaries of light and darkness on his globe over an arc of 47° 22′, in the course of his year of 88 days. Thus the regions of perpetual day and perpetual night are separated by two segments, amounting to one-fourth of the entire surface, where the sun rises and sets once in 88 days. No variation from the fierce glare on one side of the globe and the nocturnal blackness on the other can, indeed, take place. Yet these apparently intolerable climatic conditions may be somewhat mitigated by the vigorous atmospheric circulation to which they would naturally give rise.—CLERKE *History of Astronomy*, pt. ii, ch. 7, p. 305. (Bl., 1893.)

642. CONTRASTS, MAN A CREATURE OF—*Physical Insignificance and Mental Supremacy*—"*What Is Man, that Thou Art Mindful of Him? . . . Thou Hast Made Him a Little Lower than the Angels*" (*Ps. viii, 3-5*).—It is, for instance, a strange and suggestive circumstance that man, insignificant in his dimensions and in all his physical powers, when viewed in comparison even with the earth on which he lives, and compelled to remain always upon that orb, which is utterly insignificant compared with the solar system, should yet dare to raise his thoughts beyond the earth and beyond the solar system, to contemplate boldly those amazing depths amidst which the stellar glories are strewn.

That he should undertake to measure the scale on which the universe is built, to rate the stars as with swift yet stately motion they career through space, to test and analyze their very substance, to form a judgment as to processes taking place upon and around them, tho not one star in all the heavens can be magnified into more than the merest point—all this affords noble conceptions of the qualities which the Almighty has implanted in the soul of man.—PROCTOR *Expanse of Heaven*, p. 104. (L. G. & Co.)

643. CONTRIVANCE FOR FERTILIZING ORCHID—*Bee Made to Carry Pollen from Flower to Flower.*—With most orchids the flowers remain open for some time before they are visited by insects: but with spiranthes I have generally found the boat-formed disks removed very soon after their expansion. For example, in the two last spikes which I happened to examine there were numerous buds on the summit of one, with only the seven lowest flowers expanded, of which six had their disks and pollinia removed: the other spike had eight expanded flowers, and the pollinia of all were removed.

When the flowers first open they would be attractive to insects, for the receptacle already contains nectar; and at this period the rostellum lies so close to the channeled labellum that a bee could not pass down its proboscis without touching the medial furrow of the rostellum. This I know to be the case by repeated trials with a bristle. We thus see how beautifully everything is contrived that the pollinia should be withdrawn by insects visiting the flowers. They are already attached to the disk by their threads, and, from the early withering of the anther-cells, they hang loosely suspended. . . . The touch of the proboscis causes the rostellum to split in front and behind, and frees the long, narrow, boat-formed disk, which is filled with extremely viscid matter, and is sure to adhere longitudinally to the proboscis. When the bee flies away, so surely will it carry away the pollinia.—DARWIN *Fertilization of Orchids*, ch. 4, p. 111. (A., 1898.)

644. CONTRIVANCE FOR SEED-DISPERSAL—*Burs of the Burdock—Animals as Distributers of Seeds.*—If you examine a burdock blossom you will find the lower part of the flower-head covered with green scales, each of which projects upward and outward, and at the tip curves over into a sharp-pointed hook, much the shape of a fish-hook. As the flower matures these hooks gradually become dry. Finally, when the seeds are ripe, the hooks are ready to catch hold of any animal that brushes against the plant. By this time the connection with the stem at the base of the flower-head has become sufficiently loosened so that the bur pulls off readily. Yet it holds on tight enough to remain attached to the plant through the winter, unless the grappling-hooks are taken hold of by some external agency. Consequently, the period during which the seeds are open to dissemination extends over many months. This, of course, is a decided advantage, for it greatly increases the chances that the seeds will be carried to other localities. When the bur becomes attached to the hair of an animal, it may be some time before it is removed. As it is rubbed by the creature or is brushed against trees or branches, it is likely to be pushed open, and the dozen or more seeds are likely, one by one, to drop to the ground. The individual seeds are rather large, in color brown mottled with black, and rather smooth except for a few slightly projecting, longitudinal ridges.—WEED *Seed-travelers*, pt. iii, p. 49. (G. & Co., 1899.)

645. ———— ———— *Seeds Shot as from Thumb and Finger.*—The witch-hazel bears a hard, woody, nutlike fruit, as large as a hazelnut; when ripe, the apex gapes open more and more, the sides pressing harder against each smooth seed, till finally it is shot, sometimes for a distance of thirty feet. —BEAL *Seed Dispersal*, ch. 6, p. 60. (G. & Co., 1898.)

646. CONTRIVANCE IN NATURE—*Beauty and Completeness of Adaptation Exceed Imagination.*—The more I study Nature, the more I become impressed with ever-increasing force that the contrivances and beautiful adaptations slowly acquired through each part, occasionally varying in a slight degree, but in many ways, with the preservation of those variations which were beneficial to the organism under complex and ever-varying conditions of life, transcend in an incomparable manner the contrivances and adaptations which the most fertile imagination of man could invent.—DARWIN *Fertilization of Orchids*, ch. 9, p. 285. (A., 1898.)

647. CONTRIVANCE NOT UNWORTHY OF THE SUPREME WILL—This idea of the relation in which law stands to will, and in which will stands to law, is familiar to us in the works of man; but it is less familiar to us as equally holding good in the works of Nature. We feel, sometimes, as if it were an unworthy notion of the will which works in Nature, to suppose that it should never act except through the use of means. But our notions of unworthiness are themselves often the unworthiest of all. They must be ruled and disciplined by observation of that which is—not founded on a priori conceptions of what ought to be. Nothing is more certain than that the whole order of Nature is one vast system of contrivance. And what is contrivance but that kind of arrangement by which the unchangeable demands of law are met and satisfied? —ARGYLL *Reign of Law*, ch. 3, p. 76. (Burt.)

648. CONTROVERSY BETWEEN HOLDERS OF PARTIAL TRUTHS—*Geologic Theories of Formation of Rocks by Fire and by Water.*—There were many well-fought battles between geologists before it was understood that these two elements [fire and water] had been equally active in building up the crust of the earth. The ground was hotly contested by the disciples of the two geological schools, one of which held that the solid envelope of the earth was exclusively due to the influence of fire, while the other insisted that it had been accumulated wholly under the agency of water. This difference of opinion grew up very naturally; for the great leaders of the two schools lived in different localities, and pursued their investigations over regions where the geological phenomena were of an entirely opposite character—the one exhibiting the effect of volcanic eruptions, the other that of stratified deposits. It was the old story of the two knights on opposite sides of the shield.—AGASSIZ *Geological Sketches*, ser. i, ch. 1, p. 6. (H. M. & Co., 1896.)

649. CONTROVERSY OVER LITTLE HILL—*Rival Schools of Cosmogony.*—Near the highroad which passes between the towns of Eger and Franzenbad in Bohemia,

there rises a small hill known as the Kammerbühl, which has attracted to itself an amount of interest and attention quite out of proportion to its magnitude or importance. During the latter part of the last century and the earlier years of the present one, the fiercest controversies were waged between the partisans of rival schools of cosmogony over this insignificant hill, some maintaining that it originated in the combustion of a bed of coal, others that its materials were entirely formed by some kind of "aqueous precipitation," and others again that the hill was the relic of a small volcanic cone. Among those who took a very active part in this controversy was the poet Goethe, who stoutly maintained the volcanic origin of the Kammerbühl, styling it "a pocket edition of a volcano" [which the excavations undertaken at his instance have proved it to be].—JUDD *Volcanoes*, ch. 5, p. 112. (A., 1899.)

650. CONVERGENCE OF SCIENCES UPON EVOLUTION—*Authority in Agreement.*—The hypothesis of evolution must be ultimately either established or disproved by its accordance or disaccordance with a vast aggregate of facts of Nature which belong to different departments of scientific inquiry. The geologist traces the succession of plants and animals in paleontological order, and finds, as he advances in his studies, less and less evidence of interruption, and more and more of continuity, biological as well as physical. The zoologist and botanist, who have been accustomed to classify their multitudinous and diversified forms of plants and animals according to their "natural affinities," find a real meaning in their classification, a new significance in their terms of relationship, when these are used to represent what might be regarded with probability as actual community of descent. The morphologist who has been accustomed to trace a "unity of type" in each great group, and especially to recognize this in the presence of rudimentary parts which must be entirely useless to the animals that possess them, delights in the new idea which gives a perfect rationale of what had previously seemed an inexplicable superfluity. And the embryologist, who carries back his studies to the earliest phases of development, and follows out the grand law of Von Baer, "from the general to the special," in the evolution of every separate type, finds the extension of that law from the individual to the whole succession of organic life impart to his soul a feeling of grandeur like that which the physical philosopher of two hundred years ago must have experienced when Newton first promulgated the doctrine of universal gravitation. And lastly, when the doctrine of evolution is looked at in its moral aspect, as one which leads man ever onwards and upwards, and which encourages his brightest anticipations of the ultimate triumph of truth over error, of knowledge over ignorance, of right over wrong, of good over evil, who shall presume to say that the convergence of all these great lines of thought, each of them the resultant of the patient toil of a whole army of scientific workers, is a fact of no account?—CARPENTER *Nature and Man*, lect. 7, p. 237. (A., 1889.)

651. CONVOLUTIONS DETERMINE SURFACE AND POWER OF BRAIN—*An Invisible Engraving in Bodily Substance Wrought by All Great Souls.*—Increase of the cerebral surface is shown not only in the general size of the organ, but to a still greater extent in the irregular creasing and furrowing of the surface. This creasing and furrowing begins to occur in the higher mammals, and in civilized man it is carried to an astonishing extent. The amount of intelligence is correlated with the number, the depth, and the irregularity of the furrows. A cat's brain has a few symmetrical creases. In an ape the creases are deepened into slight furrows, and they run irregularly, somewhat like the lines in the palm of your hand. With age and experience the furrows grow deeper and more sinuous, and new ones appear; and in man these phenomena come to have great significance. The cerebral surface of a human infant is like that of an ape. In an adult savage, or in a European peasant, the furrowing is somewhat marked and complicated. In the brain of a great scholar the furrows are very deep and crooked, and hundreds of creases appear which are not found at all in the brains of ordinary men. In other words, the cerebral surface of such a man, the seat of conscious mental life, has become enormously enlarged in area; and we must further observe that it goes on enlarging in some cases into extreme old age.—FISKE *Destiny of Man*, ch. 5, p. 48. (H. M. & Co., 1900.)

652. COOKERY AMONG PRIMITIVE WOMEN—*Cassava Griddle-cakes.*—The cooking is done after the following fashion: A large flat slab of stone is placed over a fire, and on this griddle a thin layer of meal is spread. A woman, fan in hand, sits by the fire watching. With her fan she smooths the upper surface of the cake and makes its edges round. In a few minutes one side is done, and when the cake is turned it is done in two minutes more. They are next thrown on the roof to dry, and I have often vainly tried to imitate the skill with which an Indian woman "quoits" up one of these large and thin cakes on to the roof, often high above her head. When thoroughly dried the bread is hard and crisp.—MASON *Woman's Share in Primitive Culture*, ch. 2, p. 39. (A., 1894.)

653. COOKERY, IMPORTANCE OF—*More Depends on the Cook than on the Materials Cooked—The Quality of a Soup.*—His [Benjamin Thompson's] faith in cook-

ery is well expressed in the following, where he is speaking of his experiments in feeding the Bavarian army and the poor of Munich. He says: "I constantly found that the richness or quality of a soup depended more upon the proper choice of the ingredients, and a proper management of the fire in the combination of these ingredients, than upon the quantity of solid nutritious matter employed; much more upon the art and skill of the cook than upon the sums laid out in the market."—WILLIAMS *Chemistry of Cookery,* ch. 1, p. 5. (A., 1900.)

654. COOKING, EARLY DEVICES FOR—*Boiling by Hot Stones—No Boiled Meats in Homeric Feasts—Found in Northmen's Traditions.*—In many parts of the world, among tribes who do not know how to make an earthen pot, there is found the curious art of stone-boiling, which is a sort of wet baking. The Assiniboins of North America have their name, which means "stone-boilers," from their old practise of digging a hole in the ground, lining it with a piece of the slaughtered animal's hide, and then putting in the meat with water, and hot stones to boil it. Tribes of the far West actually managed by means of red-hot stones to boil salmon and acorn-porridge in their baskets made of close-plaited roots of the spruce-fir. The process of stone-boiling has lasted on even in Europe where found convenient for heating water in wooden tubs. Linnæus on his northern tour found the Bothland people brewing beer in this way, and to this day the "rude Carinthian boor" drinks such "stone-beer," as it is called. As soon as the cooks anywhere are provided with earthen pots or metal kettles, boiling over the fire becomes easy. Yet it is curious to notice the absence of boiled meats from the feasts of the Homeric heroes, where there is so much about the joints stuck on spits to roast, and the vengeful Odysseus rolling to and fro on his bed is compared to an eager roaster turning a stuffed paunch before the blazing fire. Among the old Northmen it was otherwise, for it is told in the Edda how the warriors feast every night in Valhalla on the sodden flesh of the boar Sæhrimner, who is daily boiled in the huge kettle, and comes to life again ready for the morrow's hunt.—TYLOR *Anthropology,* ch. 11, p. 266. (A., 1899.)

655. COOKING, SCIENTIFIC VALUE OF — *Destroys Most Bacteria.* — Injurious micro-organisms in foods are, fortunately for the consumers, usually killed by cooking. Vast numbers are, as far as we know, of no harm whatever. Alarming reports of the large numbers of bacteria which are contained in this or that food are generally as irrelevant as they are incorrect. Bacteria, as we have seen, are ubiquitous. In food we have abundance of the chief thing necessary to their life and multiplication—favorable nutriment. Hence we should expect to find, in uncooked or stale food an ample supply of saprophytic bacteria. There was much wholesome truth in the assertions made some two years ago by the late Professor Kanthack, to the effect that good food as well as bad frequently contained large numbers of bacteria, and often of the same species. It is well that we should become familiarized with this idea, for its accuracy cannot be doubted, and its usefulness at the present time may not be without its beneficial effect.—NEWMAN *Bacteria,* ch. 5, p. 178. (G. P. P., 1899.)

656. COOKING THE INVENTION OF WOMAN—There are in many lands plants which in the natural state are poisonous or extremely acrid or pungent. The women of these lands have all discovered independently that boiling or heating drives off the poisonous or disagreeable element. The Indians of southern California gather the leaves and stems of several cruciferous plants, throw them into hot water, then rinse them out in cold water five or six times, then dry them and use them as boiled cabbage. This washing removes the bitter taste and certain substances which are likely to produce nausea and diarrhea. The removal of poisonous matter from tapioca by means of hot water is the discovery of savage women.—MASON *Woman's Share in Primitive Culture,* ch. 2, p. 24. (A., 1894.)

657. COOPERATION AMONG BRUTES, UNSUPPORTED STORIES OF—*Thresher and Swordfish—Pilot-fish and Shark—Blind Instinct of Remora.*—Dr. Günther, however, denies that the thresher ever attacks whales; and Professor Moseley writes me that he considers the alleged cases "very unlikely," as the hide of the whale is so tough, and the blubber so thick, that the animal would not "feel or care about the thresher, which, by falling on the whale from a height of say 20 feet, might nearly commit suicide without the whale knowing anything about it." Moreover, as regards the pilot-fish, Professor Moseley writes me that from actual observation he can fully corroborate the opinion which I have expressed. "The pilot-fish," he says, "cannot possibly hold on the shark, as it has no means of attachment"; "it is the remora (which habitually clings to the bodies of sharks) that has been mistaken for the pilot-fish. The latter is a most unfortunate fish to run as exhibiting animal intelligence. It constantly mistakes a ship for a big shark, swimming for weeks near the water-surface, just a foot in front of the cutwater. Now, if it swam just behind the stern it would get plenty of food, whereas in front of the bow it gets nothing whatever. Nevertheless, it stays on at what in a shark is of course the right place, ready to be at the beast's mouth directly food is found." [1886.]—ROMANES *Animal Intelligence,* ch. 8, p. 253. (A., 1899.)

658. COOPERATION DEPENDS UPON COMMUNICATION—*A Nervous System Quarter of a Mile Long—The Most Perfect Signal-service Triumphs.*—The success of he cooperative principle, however, depends pon one condition: the members of the erd must be able to communicate with one nother. It matters not how acute the enses of each animal may be, the strength f the column depends on the power to ransmit from one to another what impressions each may receive at any moment from vithout. Without this power the sociality f the herd is stultified; the army, having o signaling department, is powerless as an rmy. But if any member of the herd is ble by motion of head or foot or neck or ar, by any sign or by any sound, to pass on he news that there is danger near, each intantly enters into possession of the faculies of the whole. Each has a hundred eyes, oses, ears. Each has a quarter of a mile of erves. Thus numbers are strength only vhen strength is coupled with some power f intercommunication by signs. If one herd levelops this signaling system and another loes not, its chances of survival will be reater. The less equipped herds will be lowly decimated and driven to the wall; nd those which survive to propagate their ind will be those whose signal-service is nost efficient and complete.—DRUMMOND *Ascent of Man*, p. 156. (J. P., 1900.)

659. COOPERATION IN LOWER LIFE—*A Colonial Animal—Animal Resembling Plant.*—Let us pick up a piece of this "seaweed" and note its structure. You observe it resembles a fir-tree in miniature. Its total length is about four inches, and ou note that it grows rooted and fixed like ny plant on oyster-shells and other objects. Little wonder that it is called a sea-plant, or its habits and its appearance certainly end support to that view of its nature. Scan its structure, however, a little more closely by aid of this lens, and you observe hat in place of leaves or flowers the branches bear hundreds of little cups set in each side. . . . Then your gaze alights on a curious sight. You find that each of these cups or cells is tenanted by a living animal. . . .

Our sea-fir is a compound or colonial animal, which numbers its members by the hundred. It is something more, however. It appears before us as a typical example of a cooperative society. For the colony is nourished, not by the labor of one, but by the work of all its members. Each little animal unit captures food and digests it, and then delivers this nutriment over to the general store or common fund, which is circulating always through the hollow stem and branches of the colony. From this common store each unit in turn draws its own supply.

There is perfect cooperation witnessed here. No wrangling and quarreling, such as intervene in higher societies, exist. Lower life knows nothing of the overweening ambition of the twos or threes over the aims of the mass. There is no question or claim of precedence in the sea-fir democracy. All is harmony, equality, fraternity here; and the currents of sea-fir life roll onwards undisturbed by the passions of higher existence.—ANDREW WILSON *Glimpses of Nature*, ch. 9, p. 33. (Hum., 1892.)

660. COOPERATION, UNCONSCIOUS—*Flowers and Insects—Color and Fragrance Attract for a Purpose—Life Dependent on Beauty and Sweetness.*—The vegetable world is a world of still life. No higher plant has the power to move to help its neighbor, or even to help itself, at the most critical moment of its life. . . . The fertilizing pollen grows on one part of the flower, the stigma which is to receive it grows on another, or it may be on a different plant. But as these parts cannot move towards one another, the flower calls in the aid of moving things. . . . Multitudes of flowers without such aid could never seed at all. It is to these cooperations that we owe all that is beautiful and fragrant in the flower world. To attract the insect and recompense it for its trouble, a banquet of honey is spread in the heart of the flower; and to enable the visitor to find the nectar, the leaves of the flower are made showy or conspicuous beyond all other leaves. To meet the case of insects which love the dusk, many flowers are colored white; for those which move about at night and cannot see at all, the night-flowers load the darkness with their sweet perfume. The loveliness, the variegations of shade and tint, the ornamentations, the scents, the shapes, the sizes of flowers, are all the gifts of cooperation. The flower in every detail, in fact, is a monument to the cooperative principle.—DRUMMOND *Ascent of Man*, p. 234. (J. P., 1900.)

661. COORDINATION OF BODILY ACTIVITIES—*Stronger Excitement Arouses a Greater Number—Unity of the Body.*—My hand is lying quiescent on the table; something touches it lightly, a fly, or a feather: there is a rush of activity to certain muscles, and the hand is moved away. Well, supposing the two things to be remote cause and effect: the light contact—cause, the motion—effect: what may we suppose as to the intermediate links? Unless the process be something quite unique, there must be a channel of communication between the skin of the hand and the group of muscles in the shoulder, upper arm, and forearm, that unite to withdraw the hand. Assuming the concurrence of ten muscles, there must be a ramifying thread of communication from any point in the skin of the hand to all those ten muscles. . . .

Suppose now, instead of a light contact, the hand is sharply pinched in the very same place. . . . [Now] with the mere

arm movements are coupled a great many more—in the other arm, the legs, the body, and the face, besides the more concealed movements shown in the voice, which emits a cry, shout, or other exclamation. We see that any part of the skin of the hand is in connection with perhaps two hundred muscles, the notable circumstance being that a weak touch does not arouse the wider circle of movements. . . . A very bitter taste, a malodor, a screeching discord, an intense flame, will each awaken movements of limbs, body, face, and voice. Every one of the senses is in the same extensive communication with the organs of motion.—BAIN *Mind and Body*, ch. 3, p. 6. (Hum., 1880.)

662. COPPER HAMMERED INTO SHAPE—*Indians Ignorant of Casting.*—It has often been stated that the Indians possessed some method, at present unknown, by which they were enabled to harden the copper. This, however, seems to be an error. Some copper implements, which Mr. Wilson submitted to Professor Crofts, were found to be no harder than the native copper from Lake Superior. "The structure of the metal was also highly laminated, as if the instrument had been brought to its present shape by hammering out a solid mass of copper."—AVEBURY *Prehistoric Times*, ch. 8, p. 242. (A., 1900.)

663. CORAL ANIMALS FOUND BELOW THIRTY FATHOMS—*No Reefs at the Greater Depth.*—Until quite recently it was usually stated in works dealing with the structures of coral reefs that the so-called reef-building corals, that is to say the large madrepores, astræids, and others, are confined to water not deeper than thirty fathoms. This limit must now be somewhat extended, in consequence of the discovery by Captain Moore of an abundance of growing coral at a depth of forty-four fathoms in the China seas: but, nevertheless, it is perfectly true that the corals do not grow in such profusion in very deep water as to form anything that can be compared with the reefs of the shores. It is quite possible that the advantages afforded by the light, warmth, and abundance of food of the shallow water may account for the luxuriance and vigor of the reef corals, and that where the food is scarce, and the water cold and dark, as it is below fifty fathoms, the power of continuous gemmation is lost, and the rapidity of the growth and reproduction of the individual polyps is considerably diminished.—HICKSON *Fauna of the Deep Sea*, ch. 5, p. 94. (A., 1894.)

664. CORONA OF THE SUN—*Seen Only when Eclipse Abolishes the Glare.*—Owing to the scattering of light by matter floating mechanically in the earth's atmosphere, the sun is seen not sharply defined, but surrounded by a luminous glare. Now, a loud noise will drown a whisper, an intense light will quench a feeble one, and so this circumsolar glare prevents us from seeing many striking appearances round the border of the sun. The glare is abolished in total eclipses, when the moon comes between the earth and the sun, and there are then seen a series of rose-colored protuberances, stretching sometimes tens of thousands of miles beyond the dark edge of the moon. They are described by Vassenius in the "Philosophical Transactions" for 1733, and were probably observed even earlier than this. In 1842 they attracted great attention, and were then compared to Alpine snow-peaks reddened by the evening sun. That these prominences are flaming gas, and principally hydrogen gas, was first proved by M. Janssen during an eclipse observed in India, on the 18th of August, 1868.—TYNDALL *Lectures on Light*, lect. 6, p. 206. (A., 1898.)

665. ——— ——— *Stedfast Glory of Evanescent Substance.*—This outer envelope [of the sun], tho gaseous in the main, is not spherical, but has an outline exceedingly irregular and variable. It seems to be made up not of overlying strata of different density, but rather of flames, beams, and streamers, as transient and unstable as those of our own aurora borealis. It is divided into two portions, separated by a boundary as definite, tho not so regular, as that which parts them both from the photosphere. The outer and far more extensive portion, which in texture and rarity seems to resemble the tails of comets, and may almost, without exaggeration, be likened to "the stuff that dreams are made of," is known as the "coronal atmosphere," since to it is chiefly due the "corona" or glory which surrounds the darkened sun during an eclipse, and constitutes the most impressive feature of the occasion.—YOUNG *The Sun*, ch. 6, p. 191. (A., 1898.)

666. CORRECTION OF IMPRESSIONS—*A Characteristic of Normal Mental Life.*—Finally, it should never be forgotten that in normal states of mind there is always the possibility of rectifying an illusion. What distinguishes abnormal from normal mental life is the persistent occupation of the mind by certain ideas, so that there is no room for the salutary corrective effect of reflection on the actual impression of the moment, by which we are wont to "orientate," or take our bearings as to the position of things about us. In sleep, and in certain artificially produced states, much the same thing presents itself. Images become realities just because they are not instantly recognized as such by a reference to the actual surroundings of the moment. But in normal waking life this power of correction remains with us. We may not exercise it, it is true, and thus the illusion will tend to become more or less persistent and recurring; for the same law applies to true and to false perception: repetition makes the process easier. But if we only

choose to exert ourselves, we can always keep our illusions in a nascent or imperfectly developed stage.—SULLY *Illusions*, ch. 6, p. 124. (A., 1897.)

667. CORRELATION OF GROWTH —*The Law of Symmetry—Plants, Animals, and Crystals Symmetrical.*—One relation which we detect in all variations of organic growth is simply the relation of symmetry. This kind and degree of correlation of growth prevails even in the world which we call inorganic. The corresponding sides and angles of a crystal, for example, may be said to be correlated together. The nature of this relation is geometrical and numerical. It is a relation having reference to invariable rules of number. As regards its physical cause, all we can say is that it is the result of forces whose property it is to aggregate the particles of matter in definite forms, which forms are symmetrical—that is to say, they are forms having an axis with equal developments on either side. Correlation of growth, therefore, in this sense points to the work of forces, one of whose essential properties is polarity—that is, equal and similar action in opposite directions. Now, this kind of correlation of growth may be traced upwards from simple minerals through all the infinite complications of the organic world. It is unquestionably the basis of many of the correlations of growth prevailing in plants and animals. It is seen in the symmetrical arrangement of all vegetable and of all animal forms. A central axis is traceable in them all, and the bilateral or radiated arrangement of their subordinate parts is one of the most fundamental and universal of all the correlations of growth.—ARGYLL *Reign of Law*, ch. 5, p. 144. (Burt.)

668. CORRELATION OF SCIENCES —*Chemistry and Microscopy Aid Each Other.*—It should always be remembered that a chemical report and a bacteriological report should assist each other. The former is able to tell us the quantity of salts and condition of the organic matter present; the latter the number and quality of micro-organisms. Neither can take the place of the other, and, generally speaking, both are more or less useless until we can learn, by inspection and investigation of the source of the water, the origin of the organic matter or contamination. Hence a water report should contain not only a record of physical characters, of chemical constituents, and of the presence or absence of micro-organisms, injurious and otherwise, but it should also contain information obtained by personal investigation of the source. Only thus can a reasonable opinion be expected.—NEWMAN *Bacteria*, ch. 2, p. 51. (G. P. P., 1899.)

669. CORRESPONDENCE BETWEEN EMBRYOLOGY AND GEOLOGY FAILS IN PARTICULARS—When we rigorously compare the development of any animal whatever with the successive appearance of animals of the same or similar groups in geological time, we find many things which do not correspond—not merely in the want of links which we might expect to find, but in the more significant appearance, prematurely or inopportunely, of forms which we would not anticipate.—DAWSON *Facts and Fancies in Modern Science*, lect. 1, p. 66. (A. B. P. S.)

670. CORRESPONDENCE BETWEEN PITCH OF SOUND AND COLOR—*Inconceivable Number of Light-waves.*—The pitch of sound is wholly determined by the rapidity of the vibration, as the intensity is by the amplitude. What pitch is to the ear in acoustics, color is to the eye in the undulatory theory of light. Tho never seen, the lengths of the waves of light have been determined. Their existence is proved by their effects, and from their effects also their lengths may be accurately deduced. This may, moreover, be done in many ways, and, when the different determinations are compared, the strictest harmony is found to exist between them. This consensus of evidence is one of the strongest points of the undulatory theory. The shortest waves of the visible spectrum are those of the extreme violet; the longest, those of the extreme red; while the other colors are of intermediate pitch or wavelength. The length of a wave of the extreme red is such that it would require 36,918 of them, placed end to end, to cover one inch, while 64,631 of the extreme violet waves would be required to span the same distance. Now, the velocity of light, in round numbers, is 190,000 [186,414, Flammarion, "Popular Astronomy," p. 318] miles per second. Reducing this to inches, and multiplying the number thus found by 36,918, we find the number of waves of the extreme red, in 190,000 miles, to be four hundred and fifty-one millions of millions. All these waves enter the eye, and strike the retina at the back of the eye in one second. In a similar manner, it may be found that the number of shocks corresponding to the impression of violet is seven hundred and eighty-nine millions of millions.—TYNDALL *Lectures on Light*, lect. 2, p. 62. (A., 1898.)

671. CORRESPONDENCE DEMANDS A PLAN—*The Natural Includes the Supernatural.*—Here the supermaterial, and in this sense the supernatural, element—that is to say, the ideal conformity and unity of conception—is the one unquestionable fact in which we recognize directly the working of a mind with which our own has very near relations. Here, as elsewhere, we see the natural, in the largest sense, including and embodying the supernatural; the material, including the supermaterial. No possible theory, whether true or false, in respect to the physical means employed to preserve the correspondence of parts which runs through all creation, can affect the certainty of that

mental plan and purpose which alone makes such correspondence intelligible to us, and in which alone it may be said to exist.—ARGYLL *Reign of Law*, ch. 1, p. 19. (Burt.)

672. CORRESPONDENCE OF ANIMAL ORGANS—*Likeness Found Only in an Order of Thought.*—An order so vast as this, including within itself such variety of detail, and maintained through such periods of time, implies combination and adjustment founded upon, and carrying into effect, one vast conception. It is only as an order of thought that the doctrine of animal homologies is intelligible at all. It is a mental order, and can only be mentally perceived. For what do we mean when we say that this bone in one kind of animal corresponds to such another bone in another kind of animal? Corresponds—in what sense? Not in the method of using it—for very often limbs which are homologically the same are put to the most diverse and opposite uses. To what standard, then, are we referring when we say that such and such two limbs are homologically the same? It is to the standard of an ideal order—a plan—a type—a pattern mentally conceived. This sounds very recondite and metaphysical; and yet the habit of referring physical facts to some ideal standard and order of thought is a universal instinct in the human mind. It is one of the earliest of our efforts in endeavoring to understand the phenomena around us.—ARGYLL *Reign of Law*, ch. 4, p. 117. (Burt.)

673. COSMOGONY OF DANTE WRECKED BY COPERNICAN ASTRONOMY—*Men Thought Christianity Threatened.*—With the advent of the Copernican astronomy the funnel-shaped inferno, the steep mountain of purgatory crowned with its terrestrial paradise, and those concentric spheres of heaven wherein beatified saints held weird and subtle converse, all went their way to the limbo prepared for the childlike fancies of untaught minds, whither Hades and Valhalla had gone before them. In our day it is hard to realize the startling effect of the discovery that man does not dwell at the center of things, but is the denizen of an obscure and tiny speck of cosmical matter quite invisible amid the innumerable throng of flaming suns that make up our galaxy. To the contemporaries of Copernicus the new theory seemed to strike at the very foundations of Christian theology.—FISKE *Destiny of Man*, ch. 1, p. 15. (H. M. & Co., 1900.)

674. COSMOGONY, ORIENTAL—*Hindu Account of Creation—Ordinances of Menû.*—The earliest doctrines of the Indian and Egyptian schools of philosophy agreed in ascribing the first creation of the world to an omnipotent and infinite being. They concurred also in representing this being, who had existed from all eternity, as having repeatedly destroyed and reproduced the world and all its inhabitants. In the sacred volume of the Hindus, called the "Ordinances of Menû," comprising the Indian system of duties religious and civil, we find a preliminary chapter treating of the creation, in which the cosmogony is known to have been derived from earlier writings and traditions, and principally from certain hymns of high antiquity, called the Vedas. These hymns were first put together, according to Mr. Colebrooke, in a connected series, about thirteen centuries before the Christian era, but they appear from internal evidence to have been written at various antecedent periods. In them, as we learn from the researches of Professor Wilson, the eminent Sanskrit scholar, two distinct philosophical systems are discoverable. According to one of them, all things were originally brought into existence by the sole will of a single first cause, which existed from eternity; according to the other, there have always existed two principles, the one material, but without form, the other spiritual and capable of compelling "inert matter to develop its sensible properties." This development of matter into "individual and visible existences" is called creation, and is assigned to a subordinate agent, or the creative faculty of the Supreme Being embodied in the person of Brahma.—LYELL *Principles of Geology*, bk. i, ch. 2, p. 4. (A., 1854.)

675. COST OF PLEASURE AND PAIN—*Expenditure of Blood and Nerve-tissue—Waste of Life-force by Stimulants.*—Every throb of pleasure costs something to the physical system; and two throbs cost twice as much as one. If we cannot fix a precise equivalent, it is not because the relation is not definite, but from the difficulties of reducing degrees of pleasure to a recognized standard. Of this, however, there can be no reasonable doubt—namely, that a large amount of pleasure supposes a corresponding large expenditure of blood and nerve-tissue, to the stinting, perhaps, of the active energies and the intellectual processes. It is a matter of practical moment to ascertain what pleasures cost least, for there are thrifty and unthrifty modes of spending our brain and heart's blood. Experience probably justifies us in saying that the narcotic stimulants are, in general, a more extravagant expenditure than the stimulation of food, society, and fine art. One of the safest of delights, if not very acute, is the delight of abounding physical vigor; for, from the very supposition, the supply to the brain is not such as to interfere with the general interests of the system. But the theory of pleasure is incomplete without the theory of pain.

As a rule, pain is a more costly experience than pleasure, altho sometimes economical as a check to the spendthrift pleasures. Pain is physically accompanied by an excess of blood in the brain, from at least two causes—extreme intensity of nervous action

and conflicting currents, both being sources of waste. . . . The ideally best condition is a moderate surplus of pleasure—a gentle glow, not rising into brilliancy or intensity, except at considerable intervals (say a small portion of every day), falling down frequently to indifference, but seldom sinking into pain.—BAIN app. to *Conservation of Energy*, by STEWART, p. 429. (Hum., 1880.)

676. COSTUME CHANGED WITH SEASON—*Mystery of Color among Birds.*—Quite apart from the changes in color due to age, a bird may throughout its life change costumes with the seasons. Thus, the male bobolink, after the nesting season, exchanges his black, white, and buff nuptial suit for a sparrowlike dress resembling that of his mate. The scarlet tanager sheds his gay body plumage and puts on the olive-green colors of the female, without changing, however, the color of his black wings and tail. The following spring both birds resume the more conspicuous coats. A more or less similar change takes place among many birds in which the male is brighter than the female, but, among land birds, when the adults of both sexes are alike, there is little or no seasonal change in color.—CHAPMAN *Bird-Life*, ch. 3, p. 37. (A., 1900.)

677. COUNTING, METHODS OF, AMONG SAVAGES—Even the comparatively intellectual Zulus can only count up to ten by using the hands and fingers. The Ahts of Northwest America count in nearly the same manner, and most of the tribes of South America are no further advanced. Somewhat higher races, as the Eskimos, can count up to twenty by using the hands and the feet; and other races get even further than this by saying "one man" for twenty, "two men" for forty, and so on, equivalent to our rural mode of reckoning by scores.—WALLACE *Darwinism*, ch. 15, p. 312. (Hum.)

678. COURAGE AND RESOLUTION OF SCIENTIST—*Gorge Cut by River Explored.*—This year I subjected the famous Finsteraarschlucht to a closer examination than ordinary. The earthquake theory already adverted to was prevalent regarding it, and I wished to see whether any evidences existed of aqueous erosion. It will be remembered that the Schlucht or gorge is cut through a great barrier of limestone rock called the Kirchet, which throws itself across the valley of Hasli, about three-quarters of an hour's walk above Meyringen. . . . It was regarding the sides of the great chasm that I needed instruction, and from its edge I could see nothing to satisfy me. I therefore stripped and waded into the river until a point was reached which commanded an excellent view of both sides of the gorge. The water was cutting, but I was repaid. Below me on the left-hand side was a jutting cliff, which bore the thrust of the river and caused the Aar to swerve from its direct course. From top to bottom this cliff was polished, rounded, and scooped. There was no room for doubt. The river which now runs so deeply down had once been above. It has been the delver of its own channel through the barrier of the Kirchet.—TYNDALL *Hours of Exercise in the Alps*, ch. 22, p. 256. (A., 1898.)

679. COURTSHIP AN EDUCATIONAL SEASON—*Giving Love Time for Development.*—Courtship, with its vivid perceptions and quickened emotions, is a great opportunity for evolution; and to institute and lengthen reasonably a period so rich in impression is one of its latest and highest efforts. To give love time, indeed, has been all along, and through a great variety of arrangements, the chief means of establishing it on the earth.—DRUMMOND *Ascent of Man*, p. 304. (J. P., 1900.)

680. CRAMMING SCIENTIFICALLY BAD—*Hasty Learning Opens Few Lines of Association—Oblivion a Sure Result.*—The reason why cramming is such a bad mode of study is now made clear. I mean by cramming that way of preparing for examinations by committing "points" to memory during a few hours or days of intense application immediately preceding the final ordeal, little or no work having been performed during the previous course of the term. Things learned thus in a few hours, on one occasion, for one purpose, cannot possibly have formed many associations with other things in the mind. Their brain-processes are led into by few paths, and are relatively little liable to be awakened again. Speedy oblivion is the almost inevitable fate of all that is committed to memory in this simple way. Whereas, on the contrary, the same materials taken in gradually, day after day, recurring in different contexts, considered in various relations, associated with other external incidents, and repeatedly reflected on, grow into such a system, form such connections with the rest of the mind's fabric, lie open to so many paths of approach, that they remain permanent possessions. This is the intellectual reason why habits of continuous application should be enforced in educational establishments.—JAMES *Psychology*, vol. i, ch. 16, p. 663. (H. H. & Co., 1899.)

681. CREATION A COMING-TO-BE—*Creative Power May Use Preexisting Material—"The Dust of the Ground."*—I do not know on what authority it is that we so often speak as if creation were not creation unless it work from nothing as its material, and by nothing as its means. We know that out of the "dust of the ground"—that is, out of the ordinary elements of Nature—are our own bodies formed, and the bodies of all living things. Nor is there anything which should shock us in the idea that the

creation of new forms, any more than their propagation, has been brought about by the use and instrumentality of means. In a theological point of view it matters nothing what those means have been. I agree with M. Guizot when he says that "Those only would be serious adversaries of the doctrine of creation who could affirm that the universe—the earth, and man upon it—have been from all eternity, and in all respects, just what they are now." But this cannot be affirmed except in the teeth of facts which science has clearly ascertained. There has been a continual coming-to-be of new forms of life. This is creation, no matter what have been the laws or forces employed by creative power.—ARGYLL *Reign of Law*, ch. 5, p. 156. (Burt.)

682. CREATION AND MAINTENANCE ONE IN ESSENCE—*Divine Power Acts by Wisdom and Knowledge.*—Whatever the ultimate relation may be between mental and material force, we can at least see clearly this—that in Nature there is the most elaborate machinery to accomplish purpose through the instrumentality of means. It seems as if all that is done in Nature, as well as all that is done in art, were done by knowing how to do it. It is curious how the language of the great seers of the Old Testament corresponds with this idea. They uniformly ascribe all the operations of Nature—the greatest and the smallest—to the working of divine power. But they never revolt—as so many do in these weaker days—from the idea of this power working by wisdom and knowledge in the use of means; nor, in this point of view, do they ever separate between the work of first creation and the work which is going on daily in the existing world. Exactly the same language is applied to the rarest exertions of power, and to the gentlest and most constant of all natural operations. Thus the saying that "The Lord by wisdom hath founded the earth; by understanding hath he established the heavens," is coupled in the same breath with this other saying, "By his knowledge the depths are broken up, and the clouds drop down the dew" [Prov. iii, 19-20].—ARGYLL *Reign of Law*, ch. 3, p. 77. (Burt.)

683. CREATION A PRESENT FACT—*Suns Forming Now—Partially Condensed Nebulæ—Intense Heat and Activity of Gases Composing Them.*—The aspect and the chemical analysis of these nebulæ have brought again into favor the hypothesis of cosmical matter originally scattered through all space. A first condensation of this diffuse matter produces clouds of vapors or simple nebulæ. By a subsequent condensation one or more nuclei are formed in these nebulosities. These nuclei, attracting the surrounding matter, gradually increase and become stars, which afterwards, by their mutual attraction, approach each other, and group themselves into stellar clusters. We thus see nebulæ at all ages of their organization. In order to develop in the gases lines as clear and sharp as those revealed by spectrum analysis, ordinary combustion accompanied by a feeble disengagement of heat would not suffice; on the contrary, a very elevated temperature is necessary, like that produced by the electric focus. We may conclude that the fluids which constitute the nebulæ are in a state of vivid incandescence, at a temperature at least as elevated as those which we can raise. The depths of space, which are usually presented to our mind as the seat of a glacial silence, similar to that of death, are then, on the contrary, in a state of tremendous activity which our imagination can hardly conceive. Thus suns are prepared which one day, when sufficiently condensed and cooled, will rule and illuminate a certain number of planets. The planetary nebulæ seem to be bodies already very far advanced in this way of formation. We know a compound body, of which the position is 19 hours 40 minutes of right ascension and 50° 6′ of northern declination; this is a star surrounded by a nebulous atmosphere, presenting at the same time two spectra—which seems to indicate an intermediate phase of sidereal formations.—FLAMMARION *Popular Astronomy*, p. 664. (A.)

684. CREATION BY DEVELOPMENT—*A Long Course of Slow Modification—Indications of Evolution in Orchids.*—Can we feel satisfied by saying that each orchid was created, exactly as we now see it, on a certain "ideal type"; that the omnipotent Creator, having fixed on one plan for the whole order, did not depart from this plan; that he, therefore, made the same organ to perform diverse functions—often of trifling importance compared with their proper function—converted other organs into mere purposeless rudiments, and arranged all as if they had to stand separate, and then made them cohere? Is it not a more simple and intelligible view that all the *Orchideæ* owe what they have in common to descent from some monocotyledonous plant, which, like so many other plants of the same class, possessed fifteen organs, arranged alternately three within three in five whorls; and that the now wonderfully changed structure of the flower is due to a long course of slow modification—each modification having been preserved which was useful to the plant, during the incessant changes to which the organic and inorganic world has been exposed?—DARWIN *Fertilization of Orchids*, ch. 8, p. 245. (A., 1898.)

685. CREATION BY SECOND CAUSES—*God Works by Law—Law Makes Science Possible—Science Will Not Discover Too Much.*—We may be stopped indeed at the threshold of the inquiry by the suggestion that so many thousands of years ago the comets were launched upon the paths which they are now pursuing, and at such dis-

tances from the sun as to come into view at their respective times. But I may be permitted, I trust, to reject altogether such a solution as this, not assuredly because I question the Creator's power so to arrange matters if it had pleased him, but because it is rendered manifest by the most certain scientific evidence that this has not been the Creator's pleasure; that, on the contrary, he has chosen to work all things by law. It is indeed only because this is so that science has any power to ascertain the meaning of processes going on around us. It is by the recognition of law in the universe that we are led from "Nature up to Nature's God," and they err who would stay the researches which lead to the discovery of the laws of the universe, by the simple explanation that "God so willed." That he did so is certain; but science is not therefore to be checked in its inquiries, as tho there were fear of her discovering too much. The time has not yet come, nor is it likely to come, when science need take her shoes from off her feet, because of her too near approach to the great First Cause and because in that sense the ground on which she stands is holy ground. She stands on holy ground now, and has always so stood, because she deals with the ways and works of the Creator. But she approaches no nearer to the First Cause in inquiring into the birth of the solar system than in watching the growth of an ephemeron.—PROCTOR *Expanse of Heaven*, p. 137. (L. G. & Co.)

686. CREATION HIGHER THAN DESTRUCTION—*Achievement Grander than Emotion.*—Perhaps it might once for all be stated, as a law of vital action, that the dignity of the force is in an inverse ratio to its volumetrical display. It is indeed with organic action as it is with mental action. The emotional man displays considerable force, and often produces great effects in the way of destruction, but his power is vastly inferior to that of the man who has developed emotional force into the higher form of will-force, who has coordinated the passions into the calm, self-contained activity of definite productive aim. Surely, creation always testifies to a much higher energy than destruction.—MAUDSLEY *Body and Mind*, essay 3, p. 249. (A., 1898.)

687. CREATION, LENGTH OF PERIOD OCCUPIED IN—*Planetary System—Comparative Brevity of Human History.*—The length of time required by the condensation to which the primitive nebula was subjected in order to constitute our planetary system entirely defies our imagination. To count it by thousands of millions of centuries would not be an exaggeration. The experiments of Bischof on basalt seem to prove that in order to pass from the liquid state to the solid state, to cool from 2,000 degrees to 200, our globe has required 350 millions of years. The sun has existed for many more millions of centuries. What is the whole history of mankind compared with such periods?—a wave upon the ocean.—FLAMMARION *Popular Astronomy*, bk. i, ch. 7, p. 76. (A.)

688. CREATION NOT LIMITED IN METHOD—*Scripture Draws No Line between Natural and Supernatural.*—But whatever may have been the method or process of creation, it is creation still. If it were proved to-morrow that the first man was "born" from some preexisting form of life, it would still be true that such a birth must have been, in every sense of the word, a new creation. It would still be as true that God formed him "out of the dust of the earth" as it is true that he has so formed every child who is now called to answer the first question of all theologies. And we must remember that the language of Scripture nowhere draws, or seems even conscious of, the distinction which modern philosophy draws so sharply between the natural and the supernatural. All the operations of Nature are spoken of as operations of the Divine Mind. Creation is the outward embodiment of a divine idea. It is in this sense, apparently, that the narrative of Genesis speaks of every plant being formed "before it grew" [Gen. ii, 5]. But the same language is held, not less decidedly, of every ordinary birth. "Thine eyes did see my substance, yet being imperfect. In thy book all my members were written, which in continuance were fashioned, when as yet there were none of them." And these words, spoken of the individual birth, have been applied not less truly to the modern idea of the genesis of all organic life. Whatever may have been the physical or material relation between its successive forms, the ideal relation has been now clearly recognized, and reduced to scientific definition.—ARGYLL *Reign of Law*, ch. 1, p. 18. (Burt.)

689. CREATION STILL IN PROGRESS—*Jupiter Yet in Its "Geologic Age"—A Red-hot Planet.*—It would indeed seem as tho the actual globe of Jupiter were red-hot; since from time to time, when the great white cloud-belt which surrounds his torrid regions has been dispersed, a strange fiery hue has been observed over this zone, which strongly suggests the idea of a glowing central globe. And when the light of Jupiter has been measured it has been found to exceed that which would be given by a globe of equal size simply reflecting the sun's light.—PROCTOR *Expanse of Heaven*, p. 83. (L. G. & Co., 1897.)

690. ——— ——— *Life on the Moons of Jupiter.*—Jupiter appears to be a world still in process of formation, which lately—some thousands of centuries ago—served as a sun to his own system of four [five, or perhaps more] worlds. If the central body is not at present inhabited, his satellites may be. In this case, the magnificence of the spectacle presented by Jupiter himself

to the inhabitants of the satellites is worthy of our attention. Seen from the first satellite, the Jovian globe presents an immense disk of twenty degrees in diameter, or 1,400 times larger than the full moon! What a body! What a picture, with its belts, its cloud-motions, and its glowing coloration, seen from so near! What a nocturnal sun!—still warm, perhaps. Add to this the aspect of the satellites themselves seen from each other, and you have a spectacle of which no terrestrial night can give an idea.—FLAMMARION *Popular Astronomy*, bk. iv, ch. 7, p. 429. (A.)

691. ———— *The Nebula of Orion —A Vast Aggregation of Gaseous Matter—Wider than Our Solar System—Nebulæ That Cannot Be Resolved—Unformed Matter.*—On a very clear and transparent night of winter, at midnight in December, look below the belt of Orion and you will distinguish the mass of nebulous light which glimmers in that constellation. Take a telescope, even of small power, and you remark the beautiful quadruple star (it is even sextuple), θ Orionis, surrounded by the most curious of nebulæ. Here is no cluster of suns; it is luminous, gaseous matter, a little greenish. The spectroscope shows in its spectrum three bright lines sharply defined, and separated by dark intervals. A spectrum of this nature can only be produced by light which emanates from matter in the state of gas. What is this cosmical gas? [Recent researches show that this nebula contains hydrogen, but not nitrogen.—J. E. GORE.] This immense nebula, the finest in the heavens, occupies a space much vaster than our whole planetary system!—FLAMMARION *Popular Astronomy*, bk. vi, ch. 10, p. 633. (A.)

692. CREATION, SYSTEM OF, IN KORAN—*Mohammedan Intolerance a Check upon Science.*—The cosmological opinions expressed in the Koran are few, and merely introduced incidentally; so that it is not easy to understand how they could have interfered so seriously with free discussion on the former changes of the globe. The Prophet declares that the earth was created in two days, and the mountains were then placed on it; and during these, and two additional days, the inhabitants of the earth were formed; and in two more the seven heavens. There is no more detail of circumstances; and the deluge, which is also mentioned, is discussed with equal brevity. The waters are represented to have poured out of an oven—a strange fable, said to be borrowed from the Persian Magi, who represented them as issuing from the oven of an old woman. All men were drowned, save Noah and his family; and then God said: "O earth, swallow up thy waters; and thou, O heaven, withhold thy rain," and immediately the waters abated.—LYELL *Principles of Geology*, bk. i ch. 3, p. 18. (A., 1854.)

693. CREATION TRANSCENDS HUMAN THOUGHT—*"With Whom Took He Counsel, or Who Instructed Him?" (Is. xl, 12)—"Where Wast Thou when I Laid the Foundations of the Earth?" (Job xxxviii, 4-12).*—In one form or another, if we speculate at all on the development of the planetary system, our speculations are driven into conformity with the broad lines of the nebular hypothesis—so far, at least, as admitting an original material unity and motive uniformity. But we can see now, better than formerly, that these supply a bare and imperfect sketch of the truth. We should err gravely were we to suppose it possible to reconstruct, with the help of any knowledge our race is ever likely to possess, the real and complete history of our admirable system. "The subtlety of Nature," Bacon says, "transcends in many ways the subtlety of the intellect and senses of man." By no mere barren formula of evolution, indiscriminately applied all round, the results we marvel at, and by a fragment of which our life is conditioned, were brought forth; but by the manifold play of interacting forces, variously modified and variously prevailing, according to the local requirements of the design they were appointed to execute.—CLERKE *History of Astronomy*, pt. ii, ch. 9, p. 391. (Bl., 1893.)

694. CREATOR CANNOT BE DEMONSTRATED—*Origin of Life a Mystery—Decision Must Be upon Facts.*—I grant that we have no such evidence of an active creative power as science requires for positive demonstration of her laws, and that we cannot explain the processes which lie at the origin of life. . . . I bring this subject before you now, not to urge upon you this or that theory, strong as my own convictions are. . . . Whatever be your ultimate opinions on this subject, let them rest on facts and not on arguments, however plausible. This is not a question to be argued. it is one to be investigated.—AGASSIZ *Journey in Brazil*, ch. 1, p. 43. (H. M. & Co., 1896.)

695. CREATURES OF FANCY—*"Naked Specks of Protoplasm."*—"What present warrant," it has been asked, "is there for supposing that a naked, or almost naked, speck of protoplasm can withstand four, six, or eight hours' boiling?" Regarding naked specks of protoplasm I make no assertion. I know nothing about them, save as the creatures of fancy. But I do affirm, not as a "supposition," nor an "assumption," nor a "probable guess," nor as "a wild hypothesis," but as a matter of the most undoubted fact, that the spores of the hay bacillus, when thoroughly desiccated by age, have withstood the ordeal mentioned [four to eight hours' boiling].—TYNDALL *Floating Matter of the Air*, essay 3, p. 307. (A., 1895.)

696. CREDULITY ACCEPTING WORTHLESS REMEDIES—*The Silkworm Plague.*—Pamphlets about the plague [disease of silkworms] had been showered upon the public, the monotony of waste paper being broken, at rare intervals, by a more or less useful publication. "The pharmacopœia of the silkworm," wrote M. Cornalia in 1860, "is now as complicated as that of man. Gases, liquids, and solids have been laid under contribution. From chlorin to sulfurous acid, from nitric acid to rum, from sugar to sulfate of quinin—all has been invoked in behalf of this unhappy insect." The helpless cultivators, moreover, welcomed with ready trustfulness every new remedy, if only pressed upon them with sufficient hardihood. It seemed impossible to diminish their blind confidence in their blind guides. In 1863 the French Minister of Agriculture signed an agreement to pay 500,000 francs for the use of a remedy which its promoter declared to be infallible. It was tried in twelve different departments of France, and found perfectly useless. In no single instance was it successful.—TYNDALL *Floating Matter of the Air,* essay 1, p. 10. (A., 1895.)

697. CRIME NOT EXCUSED BY INTOXICATION—The time may perhaps come when the man who voluntarily resigns that self-directing power which is the noblest gift of his Creator, and gives himself over to the domination of rage, lust, jealousy, or any other bad passion which may be excited by the action of alcohol on his brain, may be regarded as not less criminal than an engine-driver who should raise the fire of his locomotive to an extra heat, and bring up its steam to its highest pressure, and then abandon it, after starting it on a career of destruction.—CARPENTER *Mental Physiology,* bk. ii, ch. 17, p. 651. (A., 1900.)

698. CRIMINALS OFTEN MORAL IMBECILES—*Physical, Mental, and Moral Degenerates—Juvenile Offenders.*—Now, if there be a class of persons who are without the moral sense, who are true moral imbeciles, it is the class of habitual criminals. All observers who have made them their study agree that they constitute a morbid or degenerate variety of mankind, marked by peculiar low physical and mental characteristics. They are scrofulous, often deformed, with badly formed, angular heads, are stupid, sluggish, deficient in vital energy, and sometimes afflicted with epilepsy. They are of weak and defective intellect, tho excessively cunning; and now a few of them are weak-minded and imbecile. The women are ugly in features, and without grace of expression or movement. The children who become juvenile criminals do not evince the educational aptitude of the higher industrial classes; they are deficient in the power of attention and application, have bad memories, and make slow progress in learning; many of them are weak in mind and body, and some of them actually imbecile. At the end of the best part of a life spent among prisoners, a prison surgeon declares himself to be mainly impressed with their extreme deficiency or perversion of moral feeling, the strength of the evil propensities of their nature, and their utter impracticability; neither kindness nor severity availing to prevent them from devising and doing wrong day by day, altho their conduct brought on them further privations.—MAUDSLEY *Body and Mind,* lect. 4, p. 110. (A., 1898.)

699. CRIMSON OF SUNSET AND SUNRISE—*Mountain-tops Shine Like Rubies—Glory Due to Dust.*—The action of the particles [of matter suspended in the air] upon the solar light increases with the atmospheric distances traversed by the sun's rays. The lower the sun, therefore, the greater the action. The shorter waves of the spectrum being more and more withdrawn, the tendency is to give the longer waves an enhanced predominance in the transmitted light. The tendency, in other words, of this light, as the rays traverse ever-increasing distances, is more and more towards red. This, I say, might be stated as an inference, but it is borne out in the most impressive manner by facts. When the Alpine sun is setting, or, better still, some time after he has set, leaving the limbs and shoulders of the mountains in shadow, while their snowy crests are bathed by the retreating light, the snow glows with a beauty and solemnity hardly equaled by any other natural phenomenon. So, also, when first illumined by the rays of the unrisen sun, the mountain-heads, under favorable atmospheric conditions, shine like rubies. And all this splendor is evoked by the simple mechanism of minute particles, themselves without color, suspended in the air.—TYNDALL *Fragments of Science,* vol. i, ch. 5, p. 141. (A., 1897.)

700. CRITICISM OF THE HUMAN EYE—*Practical Perfection through Theoretical Defects.*—The perfection of this adaptation [of the human eye], however, has been partially denied by several modern writers, who have based their denial on a statement contained in a most interesting and instructive lecture on "The Eye and Vision," given some years ago by my very distinguished friend, Professor Helmholtz. The first part of this lecture is devoted to an exposition of the structure and actions of the eye, considered merely as an optical instrument, and of those more recent researches which have shown that, in addition to retinal defects previously known, the eye is not perfectly corrected for either spherical or chromatic aberration, that the crystalline lens has by no means the perfect clearness it has been supposed to possess, and that its fibrous structure produces an irregular radiation in the image of any single bright point. "Now, it is not too much to say," continues the lecturer, "that if an optician wanted to sell

me an instrument which had all these defects, I should think myself quite justified in blaming his carelessness in the strongest terms, and giving him back his instrument." . . . Yet I have seldom met with a case so unfair as the citation of this statement without any of the qualifications which it subsequently receives. Thus, after showing that these defects scarcely reveal themselves in our ordinary vision—some of them requiring most refined methods of observation for their detection—Professor Helmholtz continues: "If I am asked why I have spent so much time in explaining the imperfection of the eye, I answer, as I said at first, that I have not done so in order to depreciate the performances of this wonderful organ, or to diminish our admiration of its construction. It was my object to make my readers understand, at the outset of our inquiry, that it is not any mechanical perfection of the organs of our senses which secures for us such wonderfully true and exact impressions of the outer world. The extraordinary value of the eye depends on the way in which we use it: its perfection is practical, not absolute, consisting not in the avoidance of every error, but in the fact that all its defects do not prevent its rendering us the most important and varied services." This "practical perfection" he afterwards defines as "adaptation to the wants of the organism"; the defects of the eye as an optical instrument being "all so counteracted that the inexactness of the image which results from their presence very little exceeds, under ordinary conditions of illumination, the limits which are set to the delicacy of sensation by the dimensions of the retinal cones."—CARPENTER *Nature and Man*, lect. 15, p. 422. (A., 1889.)

701. CRITICISM ON INADEQUATE DATA—*Geology Needs Wide Observation.*—If it be thus unsafe, however, to calculate on the depth of deposits by the altitude of hills, it is quite as unsafe for the geologist, who has studied a formation in one district, to set himself to criticize the calculations of a brother geologist by whom it has been studied in a different and widely separated district. A deposit in one locality may be found to possess many times the thickness of the same deposit in another.—MILLER *The Old Red Sandstone*, ch. 2, p. 25. (G. & L., 1851.)

702. CROWS AS DISTRIBUTERS OF SEED—*Birds That Thrive on Poison-ivy.*—Professor Barrows writes: "Crows spend only the hours of darkness at the roosts, while during at least twelve hours each day they are dispersed far and wide over the surrounding country, collecting and distributing seeds. The process of digestion—at least the preliminary process—is very rapid in crows. A caged crow, experimented on during several months in the winter of 1889-90, ate berries of poison-ivy with greater relish than any other wild fruit obtainable. He swallowed about eighty berries within a few moments, taking several mouthfuls of sand immediately afterwards; and about thirty minutes later he disgorged a large pellet, consisting entirely of sand and the seeds of the poison-ivy berries, the latter with every shred of pulp removed by the gizzardlike action of the stomach."—WEED *Seed-travellers*, pt. ii, p. 44. (G. & Co., 1899.)

703. CRUCIFYING THE FLESH—*Sustained Ideal Will Control Action.*—The strong-willed man, however, is the man who hears the still small voice unflinchingly, and who, when the death-bringing consideration comes, looks at its face, consents to its presence, clings to it, affirms it, and holds it fast, in spite of the host of exciting mental images which rise in revolt against it and would expel it from the mind. Sustained in this way by a resolute effort of attention, the difficult object erelong begins to call up its own congeners and associates, and ends by changing the disposition of the man's consciousness altogether. And with his consciousness his action changes, for the new object, once stably in possession of the field of his thoughts, infallibly produces its own motor effects. The difficulty lies in the gaining possession of that field.' Tho the spontaneous drift of thought is all the other way, the attention must be kept strained on that one object until at last it grows, so as to maintain itself before the mind with ease. . . . The mysterious tie between the thought and the motor centers next comes into play, and, in a way which we cannot even guess at, the obedience of the bodily organs follows as a matter of course.—JAMES *Psychology*, vol. ii, ch. 26, p. 563. (H. H. & Co., 1899.)

704. CRUELTY, ANCIENT, IN TREATMENT OF THE INSANE—*Brutality Resulting from Belief in Demoniac Possession.*—It was the natural result of such [medieval] views of insanity that men should treat him whom they believed to have a devil in him as they would have treated the devil could they have had the good fortune to lay hold of him. The tortures which the insane suffered from the devils that had entered into him were less than those inflicted by the devils who took charge of him. When he was not put to death as a heretic or a criminal, he was confined in a dungeon, where he lay chained on straw; his food was thrown in, and the straw raked out, through the bars; sightseers went to see him, as they went to see the wild beasts, for amusement; he was cowed by the whip, or other instrument of punishment, and was more neglected and worse treated than if he had been a wild beast. Many insane persons, too, were without doubt executed as witches, or as persons who had, through witchcraft, entered into compact with Satan.—MAUDSLEY *Body and Mind*, lect. 4, p. 102. (A., 1898.)

705. CRUELTY WELLS UP FROM THE LOWER NATURE—*A Survival of Barbarism—Easily Developed by Encouragement.*—As Rochefoucauld says, there is something in the misfortunes of our very friends that does not altogether displease us; and an apostle of peace will feel a certain vicious thrill run through him, and enjoy a vicarious brutality, as he turns to the column in his newspaper at the top of which "Shocking Atrocity" stands printed in large capitals. See the ignoble crew that escorts every great pugilist—parasites who feel as if the glory of his brutality rubbed off upon them, and whose darling hope, from day to day, is to arrange some set-to of which they may share the rapture without enduring the pains! The first blows at a prize-fight are apt to make a refined spectator sick; but his blood is soon up in favor of one party, and it will then seem as if the other fellow could not be banged and pounded and mangled enough—the refined spectator would like to reenforce the blows himself. Over the sinister orgies of blood of certain depraved and insane persons let a curtain be drawn, as well as over the ferocity with which otherwise fairly decent men may be animated, when (at the sacking of a town, for instance), the excitement of victory long delayed, the sudden freedom of rapine and of lust, the contagion of a crowd, and the impulse to imitate and outdo, all combine to swell the blind drunkenness of the killing instinct, and carry it to its extreme. No! those who try to account for this from above downwards, as if it resulted from the consequences of the victory being rapidly inferred, and from the agreeable sentiments associated with them in the imagination, have missed the root of the matter. Our ferocity is blind, and can only be explained from below. Could we trace it back through our line of descent, we should see it taking more and more the form of a fatal reflex response, and at the same time becoming more and more the pure and direct emotion that it is.—JAMES *Psychology*, vol. ii, ch. 24, p. 413. (H. H. & Co., 1899.)

706. CRY OF FOSTER-PARENT NOT UNDERSTOOD—*Bird Learns Only from Its Own Kind.*—I am very familiar with the manners of the parasitical starling or cowbird of South America. The warning cries of the foster-parent have no effect on the young cowbird at any time. Until they are able to fly they will readily devour worms from the hand of a man, even when the old birds are hovering close by and screaming their danger notes, and while their own young, if the parasite has allowed any to survive in the nest, are crouching down in the greatest fear. After the cowbird has left the nest it is still stupidly tame, and more than once I have seen one carried off from its elevated perch by a milvago hawk, when, if it had understood the warning cry of the foster-parent, it would have dropped down into the bush or grass and escaped. But as soon as the young cowbirds are able to shift for themselves, and begin to associate with their own kind, their habits change, and they become suspicious and wild like other birds.—HUDSON *Naturalist in La Plata*, ch. 5, p. 90. (C. & H., 1895.)

707. CRYSTALLIZATION REQUIRES TIME—*Enforced Suddenness Produces Imperfection—Illustrates Revolutionary Action in Society.*—The condition of perfect crystallization is, that the crystallizing force shall act with deliberation. There should be no hurry in its operations; but every molecule ought to be permitted, without disturbance from its neighbors, to exercise its own rights. If the crystallization be too sudden, the regularity disappears. Water may be saturated with sulfate of soda, dissolved when the water is hot, and afterwards permitted to cool. When cold the solution is supersaturated; that is to say, more solid matter is contained in it than corresponds to its temperature. Still the molecules show no sign of building themselves together. This is a very remarkable tho a very common fact. The molecules in the center of the liquid are so hampered by the action of their neighbors that freedom to follow their own tendencies is denied to them. Fix your mind's eye upon a molecule within the mass. It wishes to unite with its neighbor to the right, but it wishes equally to unite with its neighbor to the left; the one tendency neutralizes the other, and it unites with neither. But, if a crystal of sulfate of soda be dropped into the solution, the molecular indecision ceases. On the crystal the adjacent molecules will immediately precipitate themselves; on these again others will be precipitated, and this act of precipitation will continue from the top of the flask to the bottom, until the solution has, as far as possible, assumed the solid form. The crystals here produced are small, and confusedly arranged. The process has been too hasty to admit of the pure and orderly action of the crystallizing force. It typifies the state of a nation in which natural and healthy change is resisted, until society becomes, as it were, supersaturated with the desire for change, the change being then effected through confusion and revolution.—TYNDALL *Lectures on Light*, lect. 3, p. 102. (A., 1898.)

708. CRYSTALS, ARTIFICIAL—*Man Gives Scope to Innate Law of Matter—Each Substance Has Its Own Crystalline Form.*—Everywhere in Nature we observe this tendency to run into definite forms, and nothing is easier than to give scope to this tendency by artificial arrangements. Dissolve niter in water, and allow the water slowly to evaporate; the niter remains, and the solution soon becomes so concentrated that the liquid condition can no longer be preserved. The niter-molecules approach each other, and come at length within the range

of their polar forces. They arrange themselves in obedience to these forces, a minute crystal of niter being at first produced. On this crystal the molecules continue to deposit themselves from the surrounding liquid. The crystal grows, and finally we have large prisms of niter, each of a perfectly definite shape. Alum crystallizes with the utmost ease in this fashion. The resultant crystal is, however, different in shape from that of niter, because the poles of the molecules are differently disposed. If they be only nursed with proper care, crystals of these substances may be caused to grow to a great size.—TYNDALL *Lectures on Light*, lect. 3, p. 102. (A., 1898.)

709. CURIOSITY A TRAIT OF SEALS—*Music and Church Bells Attract Them.*—[The common seal], like other species of the group, is certainly attracted by musical sounds; probably only through curiosity, because it is similarly attracted by any unusual movements. Mr. Bell tells us, in his "British Quadrupeds," that, in the Orkney Islands, if people are passing in boats, seals will often come quite close up to the boat, and stare at them, following for a long time together; if people speak loud, they seem to wonder what may be the matter! The Church of Hoy, in Orkney, is situated near a small sandy bay, much frequented by these creatures, and it was observed that when the bell rang for divine service all the seals within hearing swam directly for the shore, and kept looking about them, as if surprised rather than frightened, and this continued as long as the bells rang.—MIVART *Types of Animal Life*, ch. 10, p. 289. (L. B. & Co., 1893.)

710. CURIOSITY OF MONKEYS—Mr. Darwin, who, in order to test the statement of Brehm that monkeys have an instinctive dread of snakes, and yet cannot "desist from occasionally satiating their curiosity in a most human fashion, by lifting up the lid of the box in which the snakes were kept," took a stuffed snake to the monkey-house at the Zoological Gardens. Mr. Darwin says: "The excitement thus caused was one of the most curious spectacles I ever beheld. . . . I then placed a live snake in a paper bag, with the mouth loosely closed, in one of the larger compartments. One of the monkeys immediately approached, cautiously opened the bag, peeped in, and instantly dashed away. Then I witnessed what Brehm has described, for monkey after monkey, with head raised high and turned on one side, could not resist taking a momentary peep into the upright bag, at the dreadful object lying quietly at the bottom."—ROMANES *Animal Intelligence*, ch. 17, p. 477. (A., 1899.)

711. CURRENT OF ELECTRICITY NON-EXISTENT—*A Figure of Speech—Electric Action by Atomic Motion—The Row of Bricks.*—Having established the so-called electric current, we will now try to show you that there really is no current. The idea of a current involves the idea of a fluid substance flowing from one point to another. When you were a boy did you never set up a row of bricks on their ends, just far enough apart so that if you pushed one over they all fell one after another? Now, imagine rows of molecules or atoms, and in your imagination they may be arranged like the bricks, so that they are affected one by the other successively with a rapidity that is akin to that of light-waves, and you can conceive how a motion may be communicated from end to end of a wire hundreds of miles in length in a small fraction of a second, and no material substance has been carried through the wire—only energy. We do not mean to say that the row of bricks illustrates the exact mode of molecular or atomic motion that takes place in a conductor. What we mean is, that in some way motion is passed along from atom to atom.—ELISHA GRAY *Nature's Miracles*, vol. iii, ch. 6, p. 53. (F. H. & H., 1900.)

712. CURRENTS AS A MEANS OF DISTRIBUTION OF ANIMAL ORGANISMS—By far the greater number of invertebrate animals freely swimming or floating in water are incapable of offering any resistance to the current, and are therefore carried along in the direction which the current itself takes. All the larvæ of sponges, polyps, annelida, tunicata, echinodermata, and very many mollusca, . . . and the medusæ, tho many of these are provided with special swimming organs, are perfectly incapable of swimming against the feeblest stream. The only invertebrate animals which are able to overcome perhaps the strongest currents are the cuttlefishes.

The well-known wealth of forms in the Mediterranean and in the Red Sea owes its origin, certainly in great part, to the action of the constant marine currents. Both these seas are connected with the ocean only by narrow straits through which a superficial current incessantly flows in. The strength of these currents may vary with the time of year and the direction of the prevailing winds, but their direction is invariable the whole year through. Hence all the animals drifting on or just below the surface, when once they have been carried in through these narrow straits, cannot easily get back to the open ocean, and so all the forms that never sink below a certain inconsiderable depth must remain in the inland sea, and only those few species or individuals which reach the deeper return current and do not leave it can be in a position to be borne back by it to the ocean. Consequently both these seas, by reason of the inflowing surface currents, are a sort of trap; everything can get in, but nothing can get out again; thus it is inevitable—and it is actually the case—that a vast accumulation of species as well as of individuals occurs in these seas, wherever

the other necessary conditions for the existence of the individual forms exist.—SEMPER *Animal Life*, ch. 9, p. 279. (A., 1881.)

713. CURRENTS, ELECTRIC, TRAVERSING THE OCEAN FLOOR—*The Submarine Telegraph.*—And now we come to the most wonderful of all telegraphs—that which transmits messages from continent to continent, for thousands of miles, under the depths of the sea. "Does it not seem all but incredible to you," said Edward Everett in his oration at the opening of Dudley Observatory, "that intelligence should travel for two thousand miles along those slender copper wires far down in the all but fathomless Atlantic, never before penetrated by aught pertaining to humanity, save when some foundering vessel has plunged with her hapless company to the eternal silence and darkness of the abyss? Does it not seem, I say, all but a miracle of art, that the thoughts of living men—the thoughts that we think up here on the earth's surface, in the cheerful light of day—about the markets and the exchanges, and the seasons, and the elections, and the treaties, and the wars, and all the fond nothings of daily life, should clothe themselves with elemental sparks, and shoot with fiery speed in a moment, in the twinkling of an eye, from hemisphere to hemisphere, far down among the uncouth monsters that wallow in the nether seas, along the wreck-paved floor, through the oozy dungeons of the rayless deep; that the last intelligence of the crops, whose dancing tassels will in a few months be coquetting with the west wind on these boundless prairies, should go flashing along the slimy decks of old sunken galleons which have been rotting for ages; that messages of friendship and love, from warm living bosoms, should burn over the cold green bones of men and women whose hearts, once as warm as ours, burst as the eternal gulfs closed and roared over them, centuries ago!"—PARK BENJAMIN *Age of Electricity*, ch. 11, p. 247. (S., 1897.)

714. CURSE OF SLAVERY—*Even Animals Degraded by Becoming Oppressors.*—Here, then [among the slave-making ants], as in the case of nestlings, the food-seeking instinct and the power of distinguishing food by sight have degenerated, and clearly in consequence of disuse. Inasmuch as a colony of red ants always owns plenty of slaves, the food-seeking instinct has become unnecessary, natural selection has ceased to affect it, and it has gradually died out. Other instincts, too, have been lost by these red ants in consequence of their habit of keeping slaves; they have quite forgotten the art of nest-building and in part that of tending their young. Other species of ants devote much attention to their pupæ, moving them about the nest from time to time, and often carrying them out into the air and sun, and they feed their larvæ with the greatest assiduity. But the red slave-making ants have no such instincts; they care nothing for their own young, and the species would become extinct if they were suddenly deprived of their slaves. So it is not only among men that there is a curse upon slavery; even animals become degraded by it.—WEISMANN *Heredity*, vol. ii, ch. 9, p. 26. (Cl. P., 1897.)

715. CUTTING BY GLACIER RESISTLESS—*Gigantic Rasp of Ice—Record "Graven with Iron Pen in Rock Forever" (Job xix, 24).*—On any surface over which water flows we shall find that the softer materials have yielded first and most completely. Hard dikes will be left standing out, while softer rocks around them are worn away—furrows will be eaten into more deeply—fissures will be widened—clay-slates will be wasted—while hard sandstone or limestone and granite will show greater resistance. Not so with surfaces over which the leveling plow of the glacier has passed. Wherever softer and harder rocks alternate, they are brought to one outline: where dikes intersect softer rock, they are cut to one level with it; where rents or fissures traverse the rock, they do not seem to have been widened or scooped out more deeply, but their edges are simply abraded on one line with the adjoining surfaces. Whatever be the inequality in the hardness of the materials of which the rock consists, even in the case of pudding-stone, the surface is abraded so evenly as to leave the impression that a rigid rasp has moved over all the undulations of the land, advancing in one and the same direction and leveling all before it.—AGASSIZ *Geological Sketches*, ser. ii, p. 40. (H. M. & Co., 1896.)

716. CYCLE OF CHANGE—*Life the Builder, Oxygen the Destroyer—Science Has No Explanation of Life.*—While the plant is in great measure made up of non-nitrogenized substances, the animal, on the other hand, consists almost entirely of albuminous compounds. The flesh, the nerves, and the bones of our bodies all contain nitrogen, and, like the vegetable albumen, are prone to decay; and this change is constantly going on in our living members. In a most profound sense, "in the midst of life we are in death." The materials of our bodies are being constantly renewed, and the great mass of their structure changes in less than a year. At every motion of your arm, and at every breath you draw, a portion of the muscles concerned is actually burned up in the effort. During life, in some utterly mysterious manner, beyond the range of all human science, the various gases and vapors of the atmosphere, together with a small amount of a few earthy salts, are elaborated into various organized structures. They first pass into the organism of the plant, and thence are transferred to the body of the animal; but no sooner are they firmly built into the animal tissues than a destructive change begins, by which before

long they are restored to the air or the soil, only to renew the same cycle of ceaseless change. Life, during its whole existence, is an untiring builder, the oxygen of the atmosphere a fell destroyer; and when at last the builders cease, then the spirit takes its heavenward flight, and leaves the frail tenement to its appointed end. Dust returns to the dust, and these mortal mists and vapors to the air.—COOKE *Religion and Chemistry*, ch. 4, p. 99. (A., 1897.)

717. CYCLES OF VOLCANIC ACTION —*Earth's Subterranean Forces Never Still.* —Geologists have been led to the conclusion . . . that the subterranean forces are in a state of continual flux over the surface of the globe. At one point of the earth's crust these forces gradually gather such energy as to rend asunder the superincumbent rock-masses and make themselves manifest at the surface in the series of phenomena characteristic of volcanic action. But after a longer or shorter interval of time—an interval which must probably be measured by millions of years—the volcanic forces die out in that area to make their appearance in another.—JUDD *Volcanoes*, ch. 9, p. 277. (A., 1899.)

718. DANCING AMONG BIRDS—*Amusements of Animals.*—There are human dances in which only one person performs at a time, the rest of the company looking on; and some birds, in widely separated genera, have dances of this kind. A striking example is the Rupicola, or cock-of-the-rock, of tropical South America. A mossy level spot of earth surrounded by bushes is selected for a dancing-place, and kept well cleared of sticks and stones; round this area the birds assemble, when a cock-bird, with vivid orange-scarlet crest and plumage, steps into it, and, with spreading wings and tail, begins a series of movements as if dancing a minuet; finally, carried away with excitement, he leaps and gyrates in the most astonishing manner, until, becoming exhausted, he retires, and another bird takes his place.—HUDSON *Naturalist in La Plata*, ch. 19, p. 261. (C. & H., 1895.)

719. DANCING ANCIENTLY A SIGNIFICANT RITE—*Passionate Fervor of Dancers—Superstitions Connected with Dance.* —Dancing may seem to us moderns a frivolous amusement; but in the infancy of civilization it was full of passionate and solemn meaning. Savages and barbarians dance their joy and sorrow, their love and rage, even their magic and religion. . . . We have enough of the savage left in us to feel how Australians leaping and yelling at a corroboree by firelight in the forest can work themselves up into frenzy for next day's fight. But with our civilized notions it is not so easy to understand that barbarians' dancing may mean still more than this; it seems to them so real that they expect it to act on the world outside. Thus among the Mandan Indians, when the hunters failed to find the buffaloes on which the tribe depended for food, every man brought out of his lodge the mask made of a buffalo's head and horns, with the tail hanging down behind, which he kept for such an emergency, and they all set to dance buffalo. Ten or fifteen masked dancers at a time formed the ring, drumming and rattling, chanting and yelling; when one was tired out he went through the pantomime of being shot with bow and arrow, skinned, and cut up; while another, who stood ready with his buffalo-head on, took his place in the dance. So it would go on, without stopping day or night, sometimes for two or three weeks, till at last these persevering efforts to bring the buffalo succeeded, and a herd came in sight on the prairie.—TYLOR *Anthropology*, ch. 12, p. 296. (A., 1899.)

720. DANCING, RELIGIOUS—*In Ancient Greece and Rome, as in Modern India.* —In ancient religion dancing came to be one of the chief acts of worship. Religious processions went with song and dance to the Egyptian temples, and Plato said that all dancing ought to be thus an act of religion. In fact, it was so to a great extent in Greece, as where the Cretan chorus, moving in measured pace, sang hymns to Apollo, and in Rome, where the Salian priests sang and danced, beating their shields, along the streets at the yearly festival of Mars. Modern civilization, in which sacred music flourishes more than ever, has mostly cast off the sacred dance. To see this near its old state the traveler may visit the temples of India, or among the lamas of Tibet watch the mummers in animal masks dancing the demons out, or the new year in, to wild music of drums and shell-trumpets. Remnants of such ceremonies, come down from the religion of England before Christian times, are still sometimes to be seen in the dances of boys and girls round the midsummer bonfire, or of the mummers at Yuletide; but even these are dying out. The dances of choristers in plumed hats and the dress of pages of Philip III.'s time, still performed before the high altar of Seville Cathedral, are now among the quaintest relics of a rite all but vanished from Christendom.—TYLOR *Anthropology*, ch. 12, p. 297. (A., 1899.)

721. DANGER, HIDDEN — *Vesuvius Seemingly an Extinct Volcano before Eruption of 79.*—From the first colonization of southern Italy by the Greeks, Vesuvius afforded no other indications of its volcanic character than such as the naturalist might infer from the analogy of its structure to other volcanoes. These were recognized by Strabo, but Pliny did not include the mountain in his list of active vents. The ancient cone was of a very regular form, terminating not as at present in two peaks, but with a summit which presented, when seen from a distance, the even outline of an abruptly

truncated cone. On the summit, as we learn from Plutarch, there was a crater with steep cliffs, and having its interior overgrown with wild vines, and with a sterile plain at the bottom. On the exterior, the flanks of the mountain were clothed with fertile fields richly cultivated, and at its base were the populous cities of Herculaneum and Pompeii. But the scene of repose was at length doomed to cease, and the volcanic fire was recalled to the main channel, which at some former unknown period had given passage to repeated streams of melted lava, sand, and scoriæ.—LYELL *Geology*, ch. 23, p. 363. (A., 1854.)

722. DANGER-SIGNALS AMONG ANIMALS—*Warning Coloration a Defense to Its Possessor.*—[Some colorations] are developed for the express purpose of rendering the species conspicuous. The reason of this is that the animals in question are either the possessors of some deadly weapons, as stings or poison-fangs, or they are uneatable, and are thus so disagreeable to the usual enemies of their kind that they are never attacked when their peculiar powers or properties are known. It is, therefore, important that they should not be mistaken for defenseless or eatable species of the same class or order, since in that case they might suffer injury, or even death, before their enemies discovered the danger or the uselessness of the attack. They require some signal or danger-flag which shall serve as a warning to would-be enemies not to attack them, and they have usually obtained this in the form of conspicuous or brilliant coloration, very distinct from the protective tints of the defenseless animals allied to them.—WALLACE *Darwinism*, ch. 9, p. 158. (Hum., 1889.)

723. DANGERS FACED BY SCIENTISTS—*"Mountain Sickness"—Rarefied Air May Be Fatal.*—The years brought round the eclipse of 1878, which was again in United States territory, the central track running directly over one of the loftiest mountains of the country, Pike's Peak, in Colorado. Pike's Peak, tho over fourteen thousand feet high, is often ascended by pleasure tourists; but it is one thing to stay there for an hour or two, and another to take up one's abode there and get acclimated—for to do the latter we must first pass through the horrors (not too strong a word) of mountain sickness. This reaches its height usually on the second or third day, and is something like violent seasickness, complicated with the sensations a mouse may be supposed to have under the bell of an air-pump. After a week the strong begin to get over it, but none but the very robust should take its chances, as we did, without preparation; for on the night before the eclipse the life of one of our little party was pronounced in danger, and he was carried down in a litter to a cabin at an altitude of about ten thousand feet, where he recovered so speedily as to be able to do good service on the following day.—LANGLEY *New Astronomy*, ch. 2, p. 50. (H. M. & Co., 1896.)

724. DANGERS OF ISOLATION—*No Man Sufficient to Himself—The Corrective of Society a Necessity for Sound Thinking.*—Neither is such a practise [of devoting oneself wholly to thinking and teaching without reading or study], in a hygienic point of view, free from the gravest dangers to the philosopher's own mind. When once he has persuaded himself that he can work out the final truth on any subject, exclusively from his own sources, he is apt to lose all measure or standard by which to be apprised when he is departing from common sense. Living only with his own thoughts, he gradually forgets the aspect they present to minds of a different mold from his own; he looks at his conclusions only from the point of view which suggested them, and from which they naturally appear perfect; and every consideration which from other points of view might present itself, either as an objection or as a necessary modification, is to him as if it did not exist. When his merits come to be recognized and appreciated, and especially if he obtains disciples, the intellectual infirmity soon becomes complicated with a moral one. The natural result of the position is a gigantic self-confidence, not to say self-conceit.—MILL *Positive Philosophy of Auguste Comte*, p. 117. (H.H. & Co., 1887.)

725. DARKNESS ATTENDED WITH COLD—*Night for Five Months.*—One of the last expeditions made for the discovery of the north pole—that of the English navigators Nares and Stephenson (May 29, 1875, to November 2, 1877)—which advanced farther than any of its predecessors—up to 82° 24′—had 142 days of solar privation—nearly five months of night! From November 6 to February 6 the night was complete and dark. Even on November 8 the darkness was so complete at noon that it was impossible to read. But soon the moon brought a reflection of the vanished sun, and turned round the pole without ever setting for ten times twenty-four hours. The thermometer went down to 58° centigrade below zero! (It has been seen still lower at Werchojansk, in Siberia—68°.) These low temperatures are never accompanied with wind: otherwise no human being could stand such cold. O icy solitudes of the pole, you have already received heroes who have lain down forever in your gloomy shroud! The road to the pole is always marked with martyrs; but it is not the odious war of man against man: it is the triumph of mind over matter, the conquest of Nature by genius!—FLAMMARION *Popular Astronomy*, p. 31. (A.)

726. DARKNESS BEFORE DAWN OF NEW ERA—*Summary of Human Knowledge of the Stars through All Centuries before 1775.*—A star in the Swan was per-

ceived by Janson in 1600 to show fluctuations of light, and Montanari found, in 1669, that Algol in Perseus shared the same peculiarity to a marked degree. Altogether the class embraced, in 1782, half a dozen members. When it is added that a few star couples had been noted in singularly, but it was supposed accidentally, close juxtaposition, and that the failure of repeated attempts to find an annual parallax pointed to distances for the stars at least 400,000 times that of the earth from the sun, the picture of sidereal science, when the last quarter of the eighteenth century began, is practically complete. It included three items of information: that the stars have motions, real or apparent; that they are immeasurably remote; and that a few shine with a periodically variable light. Nor were the facts thus scantily collected ordered into any promise of further development. They lay at once isolated and confused before the inquirer. They needed to be both multiplied and marshaled, and it seemed as if centuries of patient toil must elapse before any reliable conclusions could be derived from them. The sidereal world was thus the recognized domain of far-reaching speculations, which remained wholly uncramped by systematic research until Herschel entered upon his career as an observer of the heavens.—CLERKE *History of Astronomy*, ch. 1, p. 12. (Bl., 1893.)

727. DARKNESS, COLD, AND PRESSURE IN DEEP SEA—*"In the Lowest Pit, in Darkness, in the Deeps" (Ps. lxxxviii, 6).*—The peculiar physical conditions of the deep seas may be briefly stated to be these: It is absolutely dark so far as actual sunlight is concerned, the temperature is only a few degrees above freezing-point, the pressure is enormous, there is little or no movement of the water, the bottom is composed of a uniform fine soft mud, and there is no plant-life. All of these physical conditions we can appreciate except the enormous pressure. Absolute darkness we know, the temperature of the deep seas is not an extraordinary one, the absence of movement in the water and the fine soft mud are conditions that we can readily appreciate; but the pressure is far greater than anything we can realize.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 18. (A., 1894.)

728. DARKNESS IN THE DAYTIME—*Far-reaching Effect of Earthquake.*—In April, 1815, one of the most frightful eruptions recorded in history occurred in the province of Tomboro, in the island of Sumbawa, about 200 miles from the eastern extremity of Java. . . . The sound of the explosions was heard in Sumatra, at the distance of 970 geographical miles in a direct line; and at Ternate, in an opposite direction, at the distance of 720 miles. Out of a population of 12,000, in the province of Tomboro, only twenty-six individuals survived. Violent whirlwinds carried up men, horses, cattle, and whatever else came within their influence into the air; tore up the largest trees by the roots, and covered the whole sea with floating timber. Great tracts of land were covered by lava, several streams of which, issuing from the crater of the Tomboro mountain, reached the sea. So heavy was the fall of ashes that they broke into the Resident's house at Bima, forty miles east of the volcano, and rendered it, as well as many other dwellings in the town, uninhabitable. On the side of Java the ashes were carried to the distance of 300 miles, and 217 towards Celebes, in sufficient quantity to darken the air. The floating cinders to the westward of Sumatra formed, on the 12th of April, a mass two feet thick, and several miles in extent, through which ships with difficulty forced their way.

The darkness occasioned in the daytime by the ashes in Java was so profound that nothing equal to it was ever witnessed in the darkest night. Altho this volcanic dust when it fell was an impalpable powder, it was of considerable weight when compressed, a pint of it weighing twelve ounces and three-quarters. "Some of the finest particles," says Mr. Crawfurd, "were transported to the islands of Amboyna and Banda, which last is about 800 miles east from the site of the volcano, altho the southeast monsoon was then at its height." They must have been projected, therefore, into the upper regions of the atmosphere, where a counter-current prevailed.—LYELL *Principles of Geology*, bk. ii, ch. 27, p. 465. (A., 1854.)

729. DARKNESS REVEALS—*The Sun's Bright Corona Seen Only During Eclipse—Unnatural Light Attending Eclipse.*—I have witnessed three total eclipses, but I do not find that repetition dulls the interest. The first was that of 1869, which passed across the United States and was nearly central over Louisville. My station was on the southern border of the eclipse track, not very far from the Mammoth Cave in Kentucky, and I well remember that early experience. The special observations of precision in which I was engaged would not interest the reader; but while trying to give my undivided attention to these, a mental photograph of the whole spectacle seemed to be taking without my volition. First, the black body of the moon advanced slowly on the sun, as we have all seen it do in partial eclipses, without anything noticeable appearing; nor till the sun was very nearly covered did the light of day about us seem much diminished. But when the sun's face was reduced to a very narrow crescent, the change was sudden and startling, for the light which fell on us not only dwindled rapidly, but became of a kind unknown before, so that a pallid appearance overspread the face of the earth with an ugly livid hue; and as this strange wanness increased, a cold seemed to come with it. The impres-

sion was of something unnatural; but there was only a moment to note it, for the sun went out as suddenly as a blown-out gas-jet, and I became as suddenly aware that all around, where it had been, there had been growing into vision a kind of ghostly radiance, composed of separate pearly beams, looking distinct each from each, as tho the black circles where the sun once was bristled with pale streamers, stretching far away from it in a sort of crown [the corona].—LANGLEY *New Astronomy*, ch. 2, p. 39. (H. M. & Co., 1896.)

730. DARWINISM NOT ATHEISTIC—*Agnosticism and Monism—Problem of First Organisms.*—Darwinism was not necessarily atheistic or agnostic. Its author was content to assume a few living beings or independent forms to begin with, and did not propose to obtain them by any spontaneous action of dead matter, nor to account for the primary origin of life, still less of all material things. In this he was sufficiently humble and honest; but the logical weakness of his position was at once apparent. If creation was needed to give a few initial types, it might have produced others also. The followers of Darwin, therefore, more especially in Germany, at once pushed the doctrine back into agnosticism and monism, giving to it a greater logical consistency, but bringing it into violent conflict with theism and with common sense.—DAWSON *Facts and Fancies of Modern Science*, lect. 1, p. 52. (A. B. P. S.)

731. DATA, INADEQUATE, LEAD TO ERRONEOUS CONCLUSION—*Emission Theory of Light Justified by the Facts in Newton's Possession.*—The case of Newton still more forcibly illustrates the position, that in forming physical theories we draw for our materials upon the world of fact. Before he began to deal with light, he was intimately acquainted with the laws of elastic collision, which all of you have seen more or less perfectly illustrated on a billiard-table. As regards the collision of sensible masses, Newton knew the angle of incidence to be equal to the angle of reflection, and he also knew that experiment . . . had established the same law with regard to light. He thus found in his previous knowledge the material for theoretic images. He had only to change the magnitude of conceptions already in his mind to arrive at the emission theory of light. He supposed light to consist of elastic particles of inconceivable minuteness shot out with inconceivable rapidity by luminous bodies, and that such particles impinging upon smooth surfaces were reflected in accordance with the ordinary law of elastic collision. The fact of optical reflection certainly occurred as if light consisted of such particles, and this was Newton's sole justification for introducing them.—TYNDALL *Lectures on Light*, lect. 2, p. 45. (A., 1898.)

732. DAWN OF MOTHERLY VIRTUES—*Patience—Sympathy—Carefulness—Tenderness.*—Begin at the beginning again and recall the fact of woman's passive strain. A tendency to passivity means, among other things, a capacity to sit still. Be it but for a minute or an hour does not matter; the point is that the faintest possible capacity is there. For this is the embryo of patience, and if much and long nursed a fully fledged patience will come out of it. Supply next to this new virtue some definite object on which to practise, let us say a child. When this child is in trouble the mother will observe the signs of pain. Its cry will awaken associations, and in some dull sense the mother will feel with it. But "feeling with another" is the literal translation of the name of a second virtue—sympathy. From feeling with it, the parent will sooner or later be led to do something to help it; then it will do more things to help it; finally it will be always helping it. Now, to care for things is to become careful; to tend things is to become tender. Here are four virtues—patience, sympathy, carefulness, tenderness—already dawning upon mankind.—DRUMMOND *Ascent of Man*, p. 288. (J. P., 1900.)

733. DAY'S JOURNEY—*A Primitive Measure of Distance.*—The day's journey is often mentioned as a fixed distance. This is only true within wide limits, and it scarcely ever exceeds ten miles for marching. "The Indians, finding that their wives were so near as to be within one of their ordinary days' work, which seldom exceeded ten or twelve miles, determined not to rest till they had joined them."—MASON *Aboriginal American Mechanics, Memoirs of the International Congress of Anthropology*, p. 79. (Sch. P. C.)

734. DEATH, A SCIENTIST'S DEFINITION OF—*Frozen Caterpillar Revived.*—I would define death as an arrest of life, from which no lengthened revival, either of the whole or any of its parts, can take place; or, to put it concisely, as a definite arrest of life. . . . For the conception itself it is quite immaterial whether we are able to decide if death has really taken place in any particular case; however uncertain we might be, the state which we call death would be not less sharply and definitely limited. We might consider the caterpillar of *Euprepia flavia* to be dead when frozen in ice, but if it recovered after thawing and became an imago, we should say that it had only been apparently dead, that life stood still for a time, but had not ceased forever. It is only the irretrievable loss of life in an organism which we call death, and we ought to hold fast to this conception, so that it will not slip from us, and become worthless, because we no longer know what we mean by it. . . . The real proof of death is that the organized substance which pre-

viously gave rise to the phenomena of life forever ceases to originate such phenomena. This, and this alone, is what mankind has hitherto understood by death.—WEISMANN *Heredity*, vol. i, p. 114. (Cl. P., 1891.)

735. DEATH, SUDDEN, STRANGE FORMS OF—*Persons Engulfed in Earthquake Fissures.*—During the convulsions of 1692 which destroyed Port Royal, it is said that many of the fissures which were formed opened and shut. In some of these, people were entirely swallowed up and buried. In others they were trapped by the middle, and even by the neck, where if not killed instantaneously they perished slowly. Subsequently their projecting parts formed food for dogs. The earthquake which, July 18, 1880, shook the Philippines caused many fissures to be found, which in some places were so numerous that the ground was broken up into steps. Near to the village of San Antonio the soil was so disturbed that the surface of a field of sugar-canes was so altered that in some cases the top of one row of full-grown plants was on a level with the roots of the next. Into one such fissure a boat disappeared, and into another a child. Subsequently the child was excavated, and its body, which was found a short distance below the surface, was completely crushed.—MILNE *Earthquakes*, ch. 8, p. 147. (A., 1899.)

736. DEATH, THE FEIGNING OF, BY ANIMALS—*The Protective Instinct of Immobility.*—In ordinary fear, one may either run or remain semi-paralyzed. The latter condition reminds us of the so-called death-shamming instinct shown by many animals. Dr. Lindsay, in his work "Mind in Animals," says this must require great self-command in those that practise it. But it is really no feigning of death at all, and requires no self-command. It is simply a terror-paralysis which has been so useful as to become hereditary. The beast of prey does not think the motionless bird, insect, or crustacean dead. He simply fails to notice them at all; because his senses, like ours, are much more strongly excited by a moving object than by a still one. It is the same instinct which leads a boy playing "I spy" to hold his very breath when the seeker is near, and which makes the beast of prey himself in many cases motionlessly lie in wait for his victim or silently "stalk" it, by rapid approaches alternated with periods of immobility.—JAMES *Psychology*, vol. ii, ch. 24, p. 420. (H. H. & Co., 1899.)

737. DEATH UNWARNED—*Brain Destroyed before Sensation Can Reach It.*—Now, it is quite conceivable that an injury might be inflicted so rapidly that within the time required by the brain to complete the arrangements necessary to consciousness its power of arrangement might be destroyed. In such a case, tho the injury might be of a nature to cause death, this would occur without pain. Death in this case would be simply the sudden negation of life, without any intervention of consciousness whatever. The time required for a rifle-bullet to pass clean through a man's head may be roughly estimated at a thousandth of a second. Here, therefore, we should have no room for sensation [see SENSATION], and death would be painless.—TYNDALL *Fragments of Science*, vol. i, ch. 21, p. 440. (A., 1900.)

738. DEBT OF CHRISTIAN CIVILIZATION TO MOSLEMS—*Algebra Developed by Arabs—Legacy of Orient to Occident.*—Besides making laudatory mention of that which we owe to the natural science of the Arabs in both the terrestrial and celestial spheres, we must likewise allude to their contributions in separate paths of intellectual development to the general mass of mathematical science. According to recent works . . . on the history of mathematics, we learn that "the algebra of the Arabs originated from an Indian and a Greek source, which long flowed independently of one another." . . . The process of establishing a conclusion by a progressive advance from one proposition to another, which seems to have been unknown to the ancient Indian algebraists, was acquired by the Arabs from the Alexandrian school. This noble inheritance, enriched by their additions, passed in the twelfth century into the European literature of the Middle Ages. "In the algebraic works of the Indians, we find the general solution of indeterminate equations of the first degree, and a far more elaborate mode of treating those of the second, than has been transmitted to us in the writings of the Alexandrian philosophers; there is, therefore, no doubt that if the works of the Indians had reached us two hundred years earlier, and were not now first made known to Europeans, they might have acted very beneficially in favoring the development of modern analysis" [Chasles]. —HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 223. (H., 1897.)

739. DEBT OF EUROPE TO THE EAST IN EARLY DAYS—*The Use of Bronze.*—Another circumstance which strongly militates against the theory of a gradual and independent development of metallurgical knowledge in different countries is the fact that whenever we find the bronze swords or celts, "whether in Ireland, in the far West, in Scotland, in distant Scandinavia, in Germany, or still further east in the Slavonic countries, they are the same, not similar in character, but identical." . . . Tho there are certain differences, yet several varieties of celts found throughout Europe, as well as some of the swords, knives, daggers, etc., are so similar that they seem as if they must have been cast by the same maker. . . . Under these circumstances, it appears most probable that the knowledge of

metal is one of those great discoveries which Europe owes to the East, and that the use of copper was not introduced into our continent until it had been observed that by the addition of a small quantity of tin it was rendered harder and more valuable.—AVEBURY *Prehistoric Times*, ch. 3, pp. 56-57. (A., 1900.)

740. DEBT OF SCIENCE TO UNLEARNED CONTRIBUTOR—*Discovery of the Mammoth.*—It was an eventful day, not only for science, but for the world, when a Siberian fisherman chanced to observe a singular mound lying near the mouth of the River Lena, where it empties into the Arctic Ocean. During the warmer summer weather, he noticed that, as the snow gradually melted, this mound assumed a more distinct and prominent outline, and at length, on one side of it, where the heat of the sun was greatest, a dark body became exposed, which, when completely uncovered, proved to be that of an immense elephant, in so perfect a state of preservation that the dogs and wolves were attracted to it as by the smell of fresh meat, and came to feed upon it at night. The man knew little of the value of his discovery, but the story went abroad, and an Englishman traveling in Russia, being curious to verify it, visited the spot, and actually found the remains where they had been reported to lie, on the frozen shore of the Arctic Sea—strange burial-place enough for an animal never known to exist out of tropical climates. Little beside the skeleton was left, tho parts of the skin remained covered with hair, showing how perfect must have been the condition of the body when first exposed. The tusks had been sold by the fisherman; but Mr. Adams succeeded in recovering them; and collecting all the bones, except those of one foot, which had been carried off by the wolves, he had them removed to St. Petersburg, where the skeleton now stands in the Imperial Museum.—AGASSIZ *Geological Sketches*, ser. i, ch. 7, p. 182. (H. M. & Co., 1896.)

741. DECAY OF ANCIENT LIFE MINISTERS TO MODERN—*Coal and Mineral Springs—Unseen Laboratories of Nature.*—The bottom and the lower slopes of the valley are occupied by the bituminous and sulfureous schists of the fish-bed, and in these, largely impregnated with the peculiar ingredients of the formation, the famous medicinal springs of the Strath have their rise. They contain, as shown by chemical analysis, the sulfates of soda, of lime, of magnesia, common salt, and, above all, sulfureted hydrogen gas—elements which masses of sea-mud, charged with animal matter, would yield as readily to the chemist as the medicinal springs of Strathpeffer. Is it not a curious reflection, that the commercial greatness of Britain, in the present day, should be closely connected with the towering and thickly spread forests of arboraceous ferns and gigantic reeds—vegetables of strange form and uncouth names—which flourished and decayed on its surface, age after age, during the vastly extended term of the Carboniferous period, ere the mountains were yet upheaved, and when there was as yet no man to till the ground? Is it not a reflection equally curious that the invalids of the present summer should be drinking health, amid the recesses of Strathpeffer, from the still more ancient mineral and animal débris of the lower ocean of the Old Red Sandstone, strangely elaborated for vast but unreckoned periods in the bowels of the earth?—MILLER *Old Red Sandstone*, ch. 10, p. 183. (G. & L., 1851.)

742. DECAY OF CREEDS—*Severance of Theology from Nature—This Separation Not Found in Scripture—Spiritual Laws Are Laws of Nature.*—Perhaps it is not too much to say that the manifest decay which so many creeds and confessions are now suffering, arises mainly from the degree in which at least the popular expositions of them dissociate the doctrines of Christianity from the analogy and course of Nature. There is no such severance in Scripture—no shyness of illustrating divine things by reference to the natural. On the contrary, we are perpetually reminded that the laws of the spiritual world are in the highest sense laws of Nature, whose obligation, operation, and effect are all in the constitution and course of things. Hence it is that so much was capable of being conveyed in the form of parable—the common actions and occurrences of daily life being often chosen as the best vehicle and illustration of the highest spiritual truths. It is not merely, as Jeremy Taylor says, that "all things are full of such resemblances"—it is more than this—more than resemblance. It is the perpetual recurrence, under infinite varieties of application, of the same rules and principles of divine government—of the same divine thoughts, divine purposes, divine affections. Hence it is that no verbal definitions or logical forms can convey religious truth with the fulness or accuracy which belongs to narratives taken from Nature—man's nature and life being, of course, included in the term:

"And so, the Word had breath, and wrought
With human hands the Creed of creeds."
TENNYSON *In Memoriam.*

—ARGYLL *Reign of Law*, ch. 1, p. 32. (Burt.)

743. DECAY OF SPIRITUAL FACULTIES—*Moral Parasites.*—So far from ministering to growth, parasitism ministers to decay. So far from ministering to holiness, that is to wholeness, parasitism ministers to exactly the opposite. One by one the spiritual faculties droop and die, one by one from lack of exercise the muscles of the soul grow weak and flaccid, one by one the moral activities cease. So from him that hath not

is taken away that which he hath, and after a few years of parasitism there is nothing left to save.—DRUMMOND *Natural Law in the Spiritual World*, essay 9, p. 302. (H. AI.)

744. DECIMALS, THE SYSTEM OF, PROVIDED FOR IN CARBONIFEROUS PERIOD—*Numerical Relations in Nature.*—The leaves of plants are not arranged at random, but in a series of curiously related spirals, differing in different plants, but always the same in the same species and regulated by definite laws. Similar definiteness regulates the ramification of plants, which depends primarily on the arrangement of the leaves. The angle of ramification of the veins of the leaf is settled for each species of plant: so are the numbers of parts in the flower and the angular arrangement of these parts. It is the same in the animal kingdom, such numbers as 5, 6, 8, 10 being selected to determine the parts in particular animals and portions of animals. Once settled, these numbers are wonderfully permanent in geological time. The first known land reptiles appear in the Carboniferous period, and they have normally five toes; these appear in the earliest known species in the lowest beds of the Carboniferous. Their predecessors, the fishes, had numerous fin-rays; but when limbs for locomotion on land were contrived, the number five was adopted as the typical one. It still persists in the five toes and fingers of man himself. From these, as is well known, our decimal notation is derived. It did not originate in any special fitness of the number ten, but in the fact that men began to reckon by counting their ten fingers. Thus the decimal system of arithmetic, with all that follows from it, was settled millions of years ago, in the Carboniferous period, either by certain low-browed and unintelligent batrachians or by their Maker.—DAWSON *Facts and Fancies in Modern Science*, lect. 5, p. 184. (A. B. P. S.)

745. DECISION TO BE MADE HABITUAL—*Habit of Indecision To Be Avoided—Make Nervous System an Ally, Not an Enemy.*—The great thing, then, in all education, is to make our nervous system our ally instead of our enemy. It is to fund and capitalize our acquisitions, and live at ease upon the interest of the fund. For this we must make automatic and habitual, as early as possible, as many useful actions as we can, and guard against the growing into ways that are likely to be disadvantageous to us, as we should guard against the plague. The more of the details of our daily life we can hand over to the effortless custody of automatism, the more our higher powers of mind will be set free for their own proper work. There is no more miserable human being than one in whom nothing is habitual but indecision, and for whom . . . the drinking of every cup, the time of rising and going to bed every day, and the beginning of every bit of work, are subjects of express volitional deliberation. Full half the time of such a man goes to the deciding, or regretting, of matters which ought to be so ingrained in him as practically not to exist for his consciousness at all. If there be such daily duties not yet ingrained in any one of my readers, let him begin this very hour to set the matter right.—JAMES *Psychology*, vol. i, ch. 4, p. 122. (H. H. & Co., 1899.)

746. DECLINE OF CIVILIZATION—*Better Implements Converted into Poorer to Suit a Lower Grade of Workers.*—There is an instructive lesson to be learned from a remark made by an Englishman at Singapore, who noticed with surprise two curious trades flourishing there. One was to buy old English-built ships, cut them down, and rig them as junks; the other was to buy English percussion-muskets and turn them into old-fashioned flintlocks. At first sight this looks like mere stupidity, but on consideration it is seen to be reasonable enough. It was so difficult to get Eastern sailors to work ships of European rig that it answered better to provide them with the clumsier craft they were used to; and as for the guns, the hunters far away in the hot, damp forests were better off with gun-flints than if they had to carry and keep dry a stock of caps. In both cases, what they wanted was not the highest product of civilization, but something suited to the situation and easiest to be had. Now the same rule applies both to taking in new civilization and keeping up old. When the life of a people is altered by emigration into a new country, or by war and distress at home, or mixture with a lower race, the culture of their forefathers may be no longer needed or possible, and so dwindles away.—TYLOR *Anthropology*, ch. 1, p. 19. (A., 1899.)

747. DECOMPOSITION, BACTERIA OF—*Cycle of Building Up and Breaking Down.*—It is clear that there is in all animal life a double process continually going on; there is a building up (anabolism, assimilation), and there is a breaking down (katabolism, dissimilation). These processes will not balance each other throughout the whole period of animal life. We have, as possibilities, elaboration, balance, degeneration; and the products of animal life will differ in degree and in substance according to which period is in the predominance. These products we may subdivide simply into excretions during life and final materials of dissolution after death, both of which may be used more or less immediately by other forms of animal or vegetable life, or mediately after having passed to the soil. . . . The carbonic acid, water, and other simple substances like them will return to Nature and be of immediate use to vegetable life. But otherwise the cycle cannot be completed, for the more complex bodies are of no service as such to plants or animals. In order that this complex material should be of

service in the economy of Nature, and its constituents not lost, it is necessary that it should be broken down again into simpler conditions. This prodigious task is accomplished by the agency of two groups of organisms, the decomposition and denitrifying bacteria [*i. e.*, bacteria that reduce nitrates].—NEWMAN *Bacteria*, ch. 5, p. 148. (G. P. P., 1899.)

748. ——— ——— *Extensive Group of Saprophytes in Soil.* — This group [the saprophytic bacteria in soil] of micro-organisms is by far the most abundant as regards number. They live on the dead organic matter of the soil, and their function appears to be to break it down into simpler constitution. Specialization is probably progressing among them, for their name is legion, and the struggle for existence keen. After we have eliminated the economic bacteria, most of which are obviously saprophytes, the group is greatly reduced. . . . At present the decomposition, denitrifying, nitrifying, and nitrogen-fixing organisms are the only saprophytes which have been rescued from the oblivion of ages, and brought more or less into daylight. It is but our lack of knowledge which requires the present division of saprophytes whose business and place in the world is unknown.—NEWMAN *Bacteria*, ch. 5, p. 166. (G. P. P., 1899.)

749. DEFENSE OF PLANT AGAINST USELESS INSECTS—*Protection Varied with Situation.*—*Polygonum amphibium* is a very interesting case. The small rosy flowers are richly supplied with honey; but from the structure of the flower, it would not be fertilized by creeping insects [but only by winged insects]. As its name indicates, this plant grows sometimes on land, sometimes in water. Those individuals, however, which grow on dry land are covered by innumerable glandular viscid hairs, which constitute an effectual protection. On the other hand, the individuals which grow in water are protected by their situation. To them the glandular hairs would be useless, and in fact on such specimens they are not developed.—AVEBURY *Ants, Bees, and Wasps*, ch. 3, p. 56. (A., 1900.)

750. DEFINITIONS OF GOD—*Conspicuous Failure of Theology (Is. xl, 18, 25)*—*Primeval Conceptions Likely To Be as True.*—Professor Max Müller is disposed to deprecate the supposition that the "Heaven-Father" of the earliest Vedic hymns is rightly to be understood as having meant "what we mean by God." Very probably indeed it may have meant something much more simple. But not the less on that account it may have meant something quite as true. I do not know, indeed, why we should set any very high estimate on the success which has attended the most learned theologians in giving anything like form or substance to our conceptions of the Godhead. Christianity solves the difficulty by presenting, as the type of all true conceptions on the subject, the image of a Divine Humanity, and the history of a perfect life. . . . When we come to the abstract definitions of subsequent theology, they invariably end either in self-contradictions or in words in which beauty of rhythm takes the place of intelligible meaning. . . . I do not know, therefore, by what title we are to assume that "what we mean by God" is certainly so much nearer the truth than the simplest conceptions of a primeval age.—ARGYLL *Unity of Nature*, ch. 12, p. 300. (Burt.)

751. DEGENERACY BEYOND POWER OF RECOVERY—*Civilization Blights and Destroys*—*Decline of American Indians before White Man's Advent.*—It is another symptom of a wrong development being the real secret of their [the savages'] condition that the lowest of them seem to have lost even the power to rise. Tho individually capable of learning what civilized men have taught them, yet as races they have been invariably scorched by the light of civilization, and have withered before it like a plant whose roots have failed. The power of assimilation seems to have departed, as it always does depart from an organism which is worn out. This has not been the result with races which, tho very barbarous, have never sunk below the pastoral or the agricultural stage. It is remarkable that the Indian races of North America are perhaps the highest which have exhibited this fatal and irredeemable incapacity to rise: and it is precisely in their case that we have the most direct evidence of degradation by development in a wrong direction. There are abundant remains of a very ancient American civilization, which was marked by the construction of great public works and by the development of an agriculture founded on the maize, which is a cereal indigenous to the continent of America. This civilization was subsequently destroyed or lost, and then succeeded a period in which man relapsed into partial barbarism. The spots which had been first forest, then, perhaps, sacred monuments, and thirdly, cultivated ground, relapsed into forest once more. So strong is this evidence of degradation having affected the population of a great part of the American continent, that the distinguished author [Avebury, in "Prehistoric Times"] from whom these words are quoted, and who generally represents the savage as the nearest living representative of primeval man, is obliged to ask, "What fatal cause destroyed this earlier civilization? Why were these fortifications forsaken—these cities in ruins? How were the populous nations which once inhabited the rich American valleys reduced to the poor tribes of savages whom the European found there? Did the North and South once before rise up in arms against one another? Did the terrible appellation, the 'Dark and Bloody Land,' applied to Kentucky, commemorate these ancient wars?" Whatever may have been the

original cause, the process of degradation has been going on within the historic period. When Europeans first came in contact with the Indian tribes, there was more agriculture among them than there is now. They have long descended to the condition of pure hunters. The most fundamental of all the elements of a civilized and settled life—the love and practise of agriculture—has been lost. Development in the wrong direction had done its work.—ARGYLL *Unity of Nature*, ch. 10, p. 253. (Burt.)

752. DEGENERACY CONCEALED—*Blind Crustacea of Mammoth Cave Have Perfect External Eyes—The Internal Organ Ruined—Like Decay in Moral Realm.*—When one examines the little crustacea which have inhabited for centuries the lakes of the Mammoth Cave of Kentucky, one is at first astonished to find these animals apparently endowed with perfect eyes. The pallor of the head is broken by two black pigment specks, conspicuous indeed as the only bits of color on the whole blanched body; and these, even to the casual observer, certainly represent well-defined organs of vision. But what do they with eyes in these Stygian waters? There reigns an everlasting night. Is the law for once at fault? A swift incision with the scalpel, a glance with a lens, and their secret is betrayed. The eyes are a mockery. Externally they are organs of vision—the front of the eye is perfect; behind, there is nothing but a mass of ruins. The optic nerve is a shrunken, atrophied, and insensate thread. These animals have organs of vision, and yet they have no vision. They have eyes, but they see not. . . . The soul undergoing degeneration . . . possesses the power of absolute secrecy. When all within is festering decay and rottenness, a Judas, without anomaly, may kiss his Lord. This invisible consumption, like its fell analogue in the natural world, may even keep its victim beautiful while slowly slaying it. Exactly what Christ said of men [Matt. xiii. 14, 15].—DRUMMOND *Natural Law in the Spiritual World*, essay 2, p. 101. (H. Al.)

753. DEGENERACY DUE TO REASON—*False Reasoning Produces Unnatural Vices—Evolution of Degradation.*—The gift of reason is the very gift by means of which error in belief, and vice in character, are carried from one stage of development to another, until at last they may, and they often do, result in conditions of life and conduct removed by an immeasurable distance from those which are in accordance with the order and with the analogies of Nature. These are the conditions of life, very much lower, as we have seen, than those which prevail among the brutes, which it is now the fashion to assume to be the nearest type of the conditions from which the human race began its course. They are, in reality and on the contrary, conditions which could not possibly have been reached except after a very long journey. They are the goal at which men have arrived after running for many generations in a wrong direction. They are the result of evolution—they are the product of development. But it is the evolution of germs whose growth is noxious.—ARGYLL *Unity of Nature*, ch. 10, p. 262. (Burt.)

754. DEGENERATION FROM DISUSE—*Eyes and Wings.*—It is clear that degeneration as a result of disuse can only take place in an organ the activity of which depends upon its exercise, so that a real effect is produced by the discharge of function. The act of seeing involves certain chemical changes in the retina of the eye, and perhaps even in the optic nerve, processes which do not take place when the eye is no longer exposed to light. Flying involves metabolism in the muscles which move the wings, and this also ceases when flight is at an end. So that an actual retrogressive influence is exerted on certain parts of the eye and on the muscles by disuse.—WEISMANN *Heredity*, vol. ii, p. 18. (Cl. P., 1892.)

755. ——— ——— *Inaction—Self-supporting Organs of Parasites Perish—Ease the Ruin of Man and Nations.*—"Any new set of conditions," says Ray Lankester, "occurring to an animal which render its food and safety very easily attained seems to lead as a rule to degeneration; just as an active healthy man sometimes degenerates when he becomes suddenly possessed of a fortune; or as Rome degenerated when possessed of the riches of the ancient world. The habit of parasitism clearly acts upon animal organization in this way. Let the parasitic life once be secured, and away go legs, jaws, eyes, and ears; the active, highly gifted crab, insect, or annelid may become a mere sac, absorbing nourishment and laying eggs."—DRUMMOND *Natural Law in the Spiritual World*, essay 10, p. 310. (H. Al.)

756. DELIBERATION AND CHOICE FUNCTIONS OF CEREBRUM—*Prudence a Virtue in Higher Animals—Few of Their Acts Mechanical.*—No animal without it [the cerebrum or higher brain] can deliberate, pause, postpone, nicely weigh one motive against another, or compare. Prudence, in a word, is for such a creature an impossible virtue. Accordingly we see that Nature removes those functions in the exercise of which prudence is a virtue from the lower centers and hands them over to the cerebrum. Wherever a creature has to deal with complex features of the environment, prudence is a virtue. The higher animals have so to deal; and the more complex the features, the higher we call the animals. The fewer of his acts, then, can such an animal perform without the help of the organs in question. In the frog many acts devolve wholly on the lower centers; in the bird

fewer; in the rodent fewer still; in the dog very few indeed; and in apes and men hardly any at all.—JAMES *Psychology*, vol. i, ch. 2, p. 21. (H. H. & Co., 1899.)

757. DELICACY OF ADJUSTMENT—*Rostellum of Orchid Set Like a Hair-trigger.*—To show how delicate a touch suffices to cause the rostellum [of the *Listera ovata*] to explode, I may mention that I found an extremely minute hymenopterous insect vainly struggling to escape, with its head cemented by the hardened viscid matter to the crest of the rostellum and to the tips of the pollinia. The insect was not so large as one of the pollinia, and after causing the explosion had not strength enough to remove them; it was thus punished for attempting a work beyond its strength, and perished miserably. [A larger insect would have carried away the adhering pollen to drop it on the stigma of another flower.]—DARWIN *Fertilization of Orchids*, ch. 4, p. 120. (A., 1898.)

758. DELICACY OF ORGANIC STRUCTURE—*Vibrations Caught by Eye and Ear.*—All the organs of sense discharge their functions in virtue of a purely mechanical adjustment between the structure of the organ and the particular form of external force which it is intended to receive and to transmit. How fine those adjustments are can best be understood when we remember that the retina of the eye is a machine which measures and distinguishes between vibrations which are now known to differ from each other by only a few millionths of an inch. Yet this amount of difference is recorded and made instantly appreciable in the sensations of color by the adjusted mechanism of the eye. Another adjustment, precisely the same in principle, between the vibrations of sound and the structure of the ear, enables those vibrations to be similarly distinguished in another special form of the manifold language of sensation. And so of all the other organs of sense—they all perform their work in virtue of that purely mechanical adjustment which places them in a given relation to certain selected manifestations of external force, and these they faithfully transmit, according to a code of signals the nature of which is one of the primary mysteries of life, but the truthfulness of which is at the same time one of the most certain of its facts.—ARGYLL *Unity of Nature*, p. 37. (Burt.)

759. DELIVERER BECOMES A SCOURGE—*The Pharaoh Rat: His Uses and Abuses.*—A dozen years ago the rats multiplied superabundantly in the sugar plantations of Jamaica, where they gnawed the stalks, sucked the sap from the incision, and as soon as they had determined the fall of one cane abandoned it for another. This manner of operating had entailed a considerable loss upon the planters, and they concluded to exterminate the rats with energy. For this purpose, . . . six ichneumons were imported from India (*Herpestes ichneumon*, or Pharoah's rat, a kind peculiar to Egypt, Palestine, and Tunis). This species is the hereditary enemy of rats and serpents, so that, multiplying rapidly, they soon cleared the devourers from the plantations. The rats then invaded the farms and the villages, but were pursued there also by the ichneumons, destroying them as well as their offspring in the nests. . . . As for the ichneumons, so useful on their arrival, no longer having rats to devour, they then began to turn up in the poultry-yards, where they destroyed the eggs and young chickens; they have also totally exterminated the quail and the partridge of the island, whose eggs, deposited upon the ground, are an easy prey. They empty the eggs by making in each a tiny hole, and the ignorant mother bird continues to cover the sterile eggs. The Jamaicans, delivered from the rats by Pharoah's rat, are now seeking a new animal to deliver them from their deliverers.—*Revue des Sciences Naturelles Appliquées*, p. 960, 1890. (Translated for *Scientific Side-Lights.*)

760. DELTA OF THE MISSISSIPPI, ANTIQUITY OF—*Vast Time Required for Deposition.*—When I visited New Orleans, in February, 1846, I found that Dr. Riddell had made numerous experiments to ascertain the proportion of sediment contained in the waters of the Mississippi; and he concluded that the mean annual amount of solid matter was to the water as $\frac{1}{1245}$ in weight, or about $\frac{1}{3000}$ in volume. From the observations of the same gentleman, and those of Dr. Carpenter and Mr. Forshey, . . . the average width, depth, and velocity of the Mississippi, and thence the mean annual discharge of water, were deduced. I assumed 528 feet, or the tenth of a mile, as the probable thickness of the deposit of mud and sand in the delta: founding my conjecture chiefly on the depth of the Gulf of Mexico, between the southern point of Florida and the Belize, which equals on an average 100 fathoms, and partly on some borings 600 feet deep in the delta, near Lake Pontchartrain, north of New Orleans, in which the bottom of the alluvial matter is said not to have been reached. The area of the delta being about 13,600 square statute miles, and the quantity of solid matter annually brought down by the river 3,702,758,400 cubic feet, it must have taken 67,000 years for the formation of the whole: and if the alluvial matter of the plain above be 264 feet deep, or half that of the delta, it must have required 33,500 more years for its accumulation, even if its area be estimated as only equal to that of the delta, whereas it is in fact larger. If some deduction be made from the time here stated, in consequence of the effect of the driftwood, which must have aided in filling up more rapidly the space above alluded to, a far more important allowance must be made, on the other hand, for the loss of matter, owing to the finer

particles of mud not settling at the mouths of the river, but being swept out far to sea during the predominant action of the tides and the waves in the winter months, when the current of fresh water is feeble. Yet, however vast the time during which the Mississippi has been transporting its earthy burden to the ocean, the whole period, tho far exceeding, perhaps, 100,000 years, must be insignificant in a geological point of view, since the bluffs or cliffs bounding the great valley, and therefore older in date, and which are from 50 to 250 feet in perpendicular height, consist in great part of loam containing land, fluviatile, and lacustrine shells of species still inhabiting the same country.—LYELL *Principles of Geology,* bk. ii, ch. 18, p. 273. (A., 1854.)

761. DELUGES, ANCIENT TRADITIONS OF—*Floods of Ogyges and Deucalion.*—The traditions which have come down to us from remote ages of great inundations, said to have happened in Greece and on the confines of the Grecian settlements, had doubtless their origin in a series of local catastrophes, caused principally by earthquakes. The frequent migrations of the earlier inhabitants, and the total want of written annals long after the first settlement of each country, make it impossible for us at this distance of time to fix either the true localities or probable dates of these events. The first philosophical writers of Greece were, therefore, as much at a loss as ourselves to offer a reasonable conjecture on these points, or to decide how many catastrophes might sometimes have become confounded in one tale, or how much this tale may have been amplified, in after times, or obscured by mythological fiction. The floods of Ogyges and Deucalion are commonly said to have happened before the Trojan war; that of Ogyges more than seventeen and that of Deucalion more than fifteen centuries before our era. As to the Ogygian flood, it is generally described as having laid waste Attica, and was referred by some writers to a great overflowing of rivers, to which cause Aristotle also attributed the deluge of Deucalion, which, he says, affected Hellas only, or the central part of Thessaly. Others imagined the same event to have been due to an earthquake, which drew down masses of rock, and stopped up the course of the Peneus in the narrow defile between mounts Ossa and Olympus.—LYELL *Principles of Geology,* bk. ii, ch. 22, p. 356. (A., 1854.)

762. DELUSION BY SYSTEM—*Logic Disregarding Fact.*—Yet the essential and fundamental error of this [former medical] system was, and still continued to be, the false kind of logical conclusion to which it was supposed to lead; the conception that it must be possible to build a complete system which would embrace all forms of disease, and their cure, upon any one simple explanation.—HELMHOLTZ *Popular Lectures,* lect. 1, p. 212. (L. G. & Co., 1898.)

763. DELUSIONS BENEFICENT—*Alchemy Led to Chemistry—Greatness in Spite of Errors.*—Albertus Magnus, of the family of the Counts of Bollstädt, must be mentioned as an independent observer in the domain of analytic chemistry. It is true that his hopes were directed to the transmutation of the metals, but in his attempts to fulfil this object he not only improved the practical manipulation of ores, but he also enlarged the insight of men into the general mode of action of the chemical forces of Nature. His works contain some extremely acute observations on the organic structure and physiology of plants. He was acquainted with the sleep of plants, the periodical opening and closing of flowers, the diminution of the sap during evaporation from the surfaces of leaves, and with the influence of the distribution of the vascular bundles on the indentations of the leaves. . . . In his own observations, we, however, unhappily too often find that Albertus Magnus shared in the uncritical spirit of his age. He thinks he knows "that rye changes on a good soil into wheat; that from a beech-wood which has been hewn down a birch-wood will spring up from the decayed matter; and that from oak branches stuck into the earth vines arise." . . . The work of Albertus Magnus, entitled "Liber Cosmographicus de Natura Locorum," is a kind of physical geography. I have found in it observations which greatly excited my surprise, regarding the simultaneous dependence of climate on latitude and elevation, and the effect of different angles of incidence of the sun's rays in heating the earth's surface.—HUMBOLDT *Cosmos,* vol. ii, pt. ii, pp. 243-4. (H., 1897.)

764. ——— ——— *Columbus Aided by Ancient Medieval Error—Ocean Supposed Less than Land.*—In the present condition of the surface of our planet, the area of the solid is to that of the fluid parts as 1:2$\frac{4}{5}$ths (according to Rigaud, as 100:270). The islands form scarcely $\frac{1}{23}$d of the continental masses, which are so unequally divided that they consist of three times more land in the northern than in the southern hemisphere, the latter being, therefore, preeminently oceanic. . . . When we consider that nearly three-fourths of the upper surface of our planet are covered with water, we shall be less surprised at the imperfect condition of meteorology before the beginning of the present century. . . . In the Middle Ages the opinion prevailed that the sea covered only one-seventh of the surface of the globe, an opinion which Cardinal d'Ailly ("Imago Mundi," cap. 8) founded on the fourth apocryphal book of Esdras. Columbus, who derived a great portion of his cosmographical knowledge from the cardinal's work, was much interested in uphold-

ing this idea of the smallness of the sea, to which the misunderstood expression of "the ocean stream" contributed not a little.—HUMBOLDT *Cosmos*, vol. i, pp. 288-9. (H., 1897.)

765. DELUSIONS DUE TO NATURAL CAUSES—*Cause of Mirage—Reflection from a Surface of Heated Air.*—Total reflection never occurs except in the attempted passage of a ray from a more refracting to a less refracting medium; but in this case, when the obliquity is sufficient, it always occurs. The mirage of the desert, and other phantasmal appearances in the atmosphere, are in part due to it. When, for example, the sun heats an expanse of sand, the layer of air in contact with the sand becomes lighter and less refracting than the air above it; consequently, the rays from a distant object, striking very obliquely on the surface of the heated stratum, are sometimes totally reflected upwards, thus producing images similar to those produced by water. I have seen the image of a rock called Mont Tombeline distinctly reflected from the heated air of the strand of Normandy near Avranches; and by such delusive appearances the thirsty soldiers of the French army in Egypt were greatly tantalized.—TYNDALL *Lectures on Light,* lect. 1. p. 19. (A., 1898.)

766. DEMOCRACY AND ARISTOCRACY AS AFFECTING SCHOLARLY PURSUITS—*Social Permanence Favors Study of Pure Science.*—In a work published in 1850, De Tocqueville says: "It must be confessed that, among the civilized peoples of our age, there are few in which the highest sciences have made so little progress as in the United States." He declares his conviction that, had you been alone in the universe, you would soon have discovered that you cannot long make progress in practical science without cultivating theoretic science at the same time. But, according to De Tocqueville, you are not thus alone. He refuses to separate America from its ancestral home; and it is there, he contends, that you collect the treasures of the intellect without taking the trouble to create them. De Tocqueville evidently doubts the capacity of a democracy to foster genius as it was fostered in the ancient aristocracies. "The future," he says, "will prove whether the passion for profound knowledge, so rare and so fruitful, can be born and developed so readily in democratic societies as in aristocracies. As for me," he continues, "I can hardly believe it." He speaks of the unquiet feverishness of democratic communities, not in times of great excitement, for such times may give an extraordinary impetus to ideas, but in times of peace. There is then, he says, "a small and uncomfortable agitation, a sort of incessant attrition of man against man, which troubles and distracts the mind without imparting to it either loftiness or animation."—TYNDALL *Lectures on Light,* p. 225. (A., 1898.)

767. DEMONSTRATION DEFINED—*Circumstantial Evidence May Have Equal Force.*—What we call "demonstration" rests entirely upon our mental inability to accept as true anything that contravenes the thing affirmed; and if, in a chain of demonstrative reasoning, every link has the strength of a necessary truth, we accept its conclusion as having the same validity as the datum from which it started. Now, I hold that exactly the same state of "conviction" may be produced by a concurrence of probabilities, if these point separately and independently to the same conclusion—like radial lines that converge from different parts of the circumference of a circle, tho none actually reach its center. For the result of that concurrence may be as irresistibly probative as any demonstration; the conclusion to which they all point being one which we are compelled to accept by our inability to conceive of any other explanation of the whole aggregate of evidentiary facts, tho any one of them may be otherwise accounted for. I am not aware that this principle has been discussed in any treatise on logic; but it is familiar to every lawyer who practises in courts of justice, and its validity cannot, I think, be questioned by any one who has studied the theory of what is commonly called "circumstantial" evidence. Indeed, it would be difficult to adduce a more remarkable example of the stability of an argument erected on a broad basis of independent probabilities than is presented in the wonderful fabric built up by the genius of Darwin; the general acceptance of the evolution doctrine resting on exactly the same kind of evidence as that on which I base the argument from design.—CARPENTER *Nature and Man,* lect. 15, p. 415. (A., 1889.)

768. DENIAL OF THEOLOGY NOT ABANDONMENT OF RELIGION—*Religious Habit of Mind as a Survival.*—Sects or individuals, who have come to reject all definite theological conceptions and to deny the existence of a living God, have, nevertheless, been able to retain feelings and sentiments which may justly claim to be called religious. In the first place, with many men of this kind, their denial of a God is not in reality a complete denial. What they deny is very often only some particular conception of the Godhead, which is involved, or which they think is involved, in the popular theology. They are repelled, perhaps, by the familiarity with which the least elevated of human passions are sometimes attributed to the Divine Being. Or they may be puzzled by the anomalies of Nature, and find it impossible to reconcile them intellectually with any definite conception of a Being who is both all-powerful and all-good. But in faltering under this difficulty, or under other difficulties of the same kind, and denying the possibility of forming any clear or definite conceptions of the Godhead, they do not necessarily renounce other conceptions which,

tho vague and indefinite, are nevertheless sufficient to form the nucleus of a hazy atmosphere of religious feeling and emotion. Such men may or may not recognize the fact that these feelings and emotions have been inherited from ancestors whose beliefs were purely theological, and that it is in the highest degree doubtful how long these feelings can be retained as mere survivals.—ARGYLL *Unity of Nature*, ch. 11, p. 269. (Burt.)

769. DENSITY OF SUN RELATIVELY SLIGHT—*Contraction and Evolution of Heat Must Still Go On.*—And the sun is by no means so dense as it may become. Spectrum analysis demonstrates the presence of large masses of iron and of other known constituents of the rocks. The pressure which endeavors to condense the interior is about 800 times as great as that in the center of the earth; and yet the density of the sun, owing probably to its enormous temperature, is less than a quarter of the mean density of the earth.—HELMHOLTZ *Popular Lectures*, lect. 4, p. 182. (L. G. & Co., 1898.)

770. DEPARTMENTS OF MEMORY—*Interest and Habit Control Remembrance.*—The visual, the tactile, the muscular, the auditory memory may all vary independently of each other in the same individual; and different individuals may have them developed in different degrees. As a rule, a man's memory is good in the departments in which his interest is strong; but those departments are apt to be those in which his discriminative sensibility is high. A man with a bad ear is not likely to have practically a good musical memory, or a purblind person to remember visual appearances well. [When we consider the differences in the power of imagination in different men] it is obvious that the machinery of memory must be largely determined thereby.—JAMES *Psychology*, vol. i, ch. 16, p. 684. (H. H. & Co., 1899.)

771. DEPENDENCE, INSTINCTIVE, OF INSECT ON PROTECTIVE MIMICRY—*A Leaflike Locust.*—To show how perfect is the protection obtained [by protective mimicry] and how important it is to the possessors of it, the following incident, observed by Mr. Belt in Nicaragua, is most instructive. Describing the armies of foraging ants in the forest which devour every insect they can catch, he says: "I was much surprised with the behavior of a green leaflike locust. This insect stood immovably among a host of ants, many of which ran over its legs without ever discovering there was food within their reach. So fixed was its instinctive knowledge that its safety depended on its immovability, that it allowed me to pick it up and replace it among the ants without making a single effort to escape. This species closely resembles a green leaf."—WALLACE *Darwinism*, ch. 8, p. 138. (Hum.)

772. DEPENDENCE OF ORGANISM ON ENVIRONMENT—*Of Soul on God.*—Powerlessness is the normal state . . . of every organism apart from its environment. The entire dependence of the soul upon God is not an exceptional mystery, nor is man's helplessness an arbitrary and unprecedented phenomenon. It is the law of all Nature. . . . But who will not rather approve the arrangement by which man in his creatural life may have unbroken access to an Infinite Power? What soul will seek to remain self-luminous when it knows that "The Lord God is a sun"? Who will not willingly exchange his shallow vessel for Christ's well of living water? Even if, the organism, launched into being like a ship putting out to sea, possessed a full equipment, its little store must soon come to an end. But in contact with a large and bounteous environment its supply is limitless. In every direction its resources are infinite.—DRUMMOND *Natural Law in the Spiritual World*, essay 7, pp. 241-2. (H. Al.)

773. DEPENDENCE OF SCIENCE ON MECHANICS—Scarcely less important for the practical uses of astronomy than the optical qualities of the telescope is the manner of its mounting. The most admirable performance of the optician can render but unsatisfactory service if its mechanical accessories are ill-arranged or inconvenient. Thus the astronomer is ultimately dependent upon the mechanician; and so excellently have his needs been served that the history of the ingenious contrivances by which discoveries have been prepared would supply a subject (here barely glanced at) not far inferior in extent and instruction to the history of those discoveries themselves.—CLERKE *History of Astronomy*, pt. i, ch. 6, p. 149. (Bl., 1893.)

774. DEPENDENCE OF THE GREATEST UPON THE LEAST—*Microscopic Organisms Affect the Chief Concerns of Life.*—This application of biology to life and its problems has in recent years been nowhere more marked than in the realm of bacteriology. This comparatively new science, associated with the great names of Pasteur, Koch, and Lister, furnishes indeed a stock illustration of the applicability of pure biology. Turn where we will, we shall find the work of the unseen hosts of bacteria daily claiming more and more attention from practical people. Thus biology, even when clothed in the form of microscopic cells, is coming to occupy a new place in the minds of men. "Its evolution," as Professor Patrick Geddes declares, "forms part of the general social evolution." Certainly its recent rapid development forms a remarkable feature in the practical science of our time. Not only in the diagnosis and treatment of disease, nor even in the various applications of preventive medicine, but in ever-increasing degree and sphere, microorganisms are recognized as agents of util-

ity or otherwise no longer to be ignored. They occur in our drinking water, in our milk-supply, in the air we breathe. They ripen cream and flavor butter. They purify sewage, and remove waste organic products from the land. They are the active agents in a dozen industrial fermentations. They assist in the fixation of free nitrogen, and they build up assimilable compounds. Their activity assumes innumerable phases and occupies many spheres, more frequently proving themselves beneficial than injurious. They are both economic and industrious in the best biological sense of the terms.—NEWMAN *Bacteria*, int., p. 11. (G. P. P., 1899.)

775. DEPOSIT ON DEEP-SEA FLOOR —*The Globigerina-ooze*.—The globigerina-ooze is perhaps the best known of all the different deep-sea deposits. It was discovered and first described by the officers of the American Coast Survey in 1853. It is found in great abundance in the Atlantic Ocean in regions shallower than 2,200 fathoms. . . . It is probably formed partly by the shells of the dead Foraminifera that actually live on the bottom of the ocean and partly by the shells of those that live near the surface or in intermediate depths and fall to the bottom when their lives are done.

So abundant are the shells of these Protozoa that nearly 95 per cent. of the globigerina-ooze is composed of carbonate of lime.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 37. (A., 1894.)

776. ——— ——— *The Red Mud.*—Of all the deep-sea deposits, however, the so-called "red mud" has by far the widest distribution. It is supposed to extend over one-third of the earth's surface. It is essentially a deep-sea deposit, and one that is found in its typical condition at some considerable distance from continental land. . . . To the touch it is plastic and greasy when fresh, but it soon hardens into solid masses. When examined with the microscope it is seen to be composed of extremely minute fragments rarely exceeding 0.05 mm. in diameter. It contains a large amount of free silica that is probably formed by the destruction of numerous siliceous skeletons, and a small proportion of silicate of alumina.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 39. (A., 1894.)

777. DEPOSITS, MODERN, LIKE ANCIENT—*Strata Forming Now—Land-building under Sea*.—For more than two centuries the shelly strata of the Subapenine hills afforded matter of speculation to the early geologists of Italy, and few of them had any suspicion that similar deposits were then forming in the neighboring sea. They were as unconscious of the continued action of causes still producing similar effects as the astronomers, in the case above supposed, of the existence of certain heavenly bodies still giving and reflecting light, and performing their movements as of old. Some imagined that the strata, so rich in organic remains, instead of being due to secondary agents, had been so created in the beginning of things by the fiat of the Almighty. Others, as we have seen, ascribed the embedded fossil bodies to some plastic power which resided in the earth in the early ages of the world. In what manner were these dogmas at length exploded? The fossil relics were carefully compared with their living analogues, and all doubts as to their organic origin were eventually dispelled. So, also, in regard to the nature of the containing beds of mud, sand, and limestone: those parts of the bottom of the sea were examined where shells are now becoming annually entombed in new deposits. Donati explored the bed of the Adriatic, and found the closest resemblance between the strata there forming and those which constituted hills above a thousand feet high in various parts of the Italian peninsula. He ascertained by dredging that living testacea were there grouped together in precisely the same manner as were their fossil analogues in the inland strata; and while some of the recent shells of the Adriatic were becoming incrusted with calcareous rock, he observed that others had been newly buried in sand and clay, precisely as fossil shells occur in the Subapenine hills. This discovery of the identity of modern and ancient submarine operations was not made without the aid of artificial instruments, which, like the telescope, brought phenomena into view not otherwise within the sphere of human observation.—LYELL *Principles of Geology*, bk. i, ch. 5, p. 71. (A., 1854.)

778. DEPTH OF EARTHQUAKE SHOCK—*Convulsion Originates Miles below the Surface*.—The first calculations of the depth at which an earthquake originated were those made by Mallet for the Neapolitan earthquake of 1857. By means of a number of lines parallel to twenty-six angles of emergence, drawn in towards the seismic vertical, Mallet found that twenty-three of these intersected at a depth of 7¼ geographical miles. The maximum depth was 8¼ geographical miles, and the minimum depth 2¾ geographical miles. The mean depth was taken at a depth of 5¾ geographical miles where, within a range of 12,000 feet, eighteen of the wave-paths intersected the seismic vertical. The point where these wave-paths start thickest is at a depth not greater than three geographical miles, and this is considered to be the vertical depth of the focal cavity itself. For the Yokohama earthquake of 1880, from the indications of seismometers, and by other means, certain angles of emergence were obtained, leading to the conclusion that the depth of origin of that earthquake might be between 1½ and 5 miles. Possibly, perhaps, the earthquake may have originated from a fissure the vertical dimensions of which were comprised between these depths.—MILNE *Earthquakes*, ch. 11, p. 213. (A., 1899.)

779. DEPTHS OF OCEAN PAVED WITH VOLCANIC DUST *(Job xxxvi, 30)*—Recent deep-sea soundings, carried on in the "Challenger" and other vessels, have shown that the bottom of the deepest portion of the ocean, far away from the land, is covered with these volcanic materials which have been carried through the air or floated on the surface of the ocean. To these deeper parts of the ocean no sediments carried down by the rivers are borne, and the remains of calcareous organisms are, in these abysses, soon dissolved; under such conditions, therefore, almost the only material accumulating on the sea-bottom is the ubiquitous wind- and wave-borne volcanic products. These particles of volcanic dust and fragments of pumice by their disintegration give rise to a clayey material, and the oxidation of the magnetite, which all lavas contain, communicates to the mass a reddish tint. This appears to be the true origin of those masses of "red clay" which, according to recent researches, are found to cover all the deeper parts of the ocean.—JUDD *Volcanoes*, ch. 4, p. 73. (A., 1899.)

780. DESERT, PROTECTIVE COLORS IN—*Animals Take On the Tawny Hues of Sand and Rock.*—In the desert regions of the earth we find an even more general accordance of color with surroundings. The lion, the camel, and all the desert antelopes have more or less the color of the sand or rock among which they live. The Egyptian cat and the pampas-cat are sandy or earth colored. The Australian kangaroos are of similar tints, and the original color of the wild horse is supposed to have been sandy or clay colored. Birds are equally well protected by assimilative hues; the larks, quails, goatsuckers, and grouse which abound in the North-African and Asiatic deserts are all tinted or mottled so as closely to resemble the average color of the soil in the districts they inhabit.—WALLACE *Darwinism*, ch. 8, p. 131. (Hum., 1889.)

781. DESERTS TO BE TRANSFORMED—*Power, Manufacturing and Political, To Be Centered There—Utilizing the Direct Heat of the Sun.*—Future ages may see the seat of empire transferred to regions of the earth now barren and desolated under intense solar heat—countries which, for that very cause, will not improbably become the seat of mechanical and thence of political power. Whoever finds the way to make industrially useful the vast sun-power now wasted on the deserts of North Africa or the shores of the Red Sea will effect a greater change in men's affairs than any conqueror in history has done: for he will once more people those waste places with the life that swarmed there in the best days of Carthage and of old Egypt, but under another civilization, where man no longer shall worship the sun as a god, but shall have learned to make it his servant.—LANGLEY *New Astronomy*, ch. 4, p. 115. (H. M. & Co., 1896.)

782. DESIGN, APPARENT, IN SPIDER'S CAPTURE OF INSECT—When any large insect, as a grasshopper or wasp, is caught, the spider [*Epeira* of Brazil], by a dexterous movement, makes it revolve very rapidly, and at the same time emitting a band of threads from its spinners, soon envelops its prey in a case like the cocoon of a silkworm. The spider now examines the powerless victim, and gives the fatal bite on the hinder part of its thorax; then, retreating, patiently waits till the poison has taken effect. The virulence of this poison may be judged of from the fact that in half a minute I opened the mesh and found a large wasp quite lifeless.—DARWIN *Naturalist's Voyage around the World*, ch. 2, p. 36. (A., 1898.)

783. DESIGN, EVIDENCE OF—*Eye Formed by Convergence of Opposite Growths.*—Further evidence of "intelligent design" is supplied by the history of the development of any one of the highest forms of the eye, such as that of the chick *in ovo*. For it has been ascertained by the careful study of this process that the complete organ is the joint product of two distinct developmental actions, taking place in opposite directions—a growing inwards from the skin and a growing outwards from the brain: the former supplying the optical instrument for the formation of the visual picture, and the latter furnishing the nervous apparatus on which this is received, and by which its impression is conveyed to the sensorium.—CARPENTER *Nature and Man*, lect. 15, p. 430. (A., 1889.)

784. ——— *Fertilization of Orchids.*—Perhaps no illustration more striking of this principle was ever presented than in the curious volume published by Mr. Darwin on the "Fertilization of Orchids." It appears that the fertilization of almost all orchids is dependent on the transport of the pollen from one flower to another by means of insects. It appears, further, that the structure of these flowers is elaborately contrived, so as to secure the certainty and effectiveness of this operation. Mr. Darwin's work is devoted to tracing in detail what these contrivances are. To a large extent they are purely mechanical, and can be traced with as much clearness and certainty as the different parts of which a steam-engine is composed. The complication and ingenuity of these contrivances almost exceed belief. "Moth-traps and spring-guns set on these grounds" might be the motto of the orchids. There are baits to tempt the nectar-loving Lepidoptera, with rich odors exhaled at night, and lustrous colors to shine by day; there are channels of approach along which they are surely guided, so as to compel them to pass by certain spots;

there are adhesive plasters nicely adjusted to fit their proboscides, or to catch their brows; there are hair-triggers carefully set in their necessary path, communicating with explosive shells, which project the pollen-stalks with unerring aim upon their bodies. There are, in short, an infinitude of adjustments, for an idea of which I must refer my readers to Mr. Darwin's inimitable powers of observation and description—adjustments all contrived so as to secure the accurate conveyance of the pollen of the one flower to its precise destination in the structure of another.—ARGYLL *Reign of Law*, ch. 1, p. 22. (Burt.)

785. DESIGN IN EVOLUTION—*Plan Extended through Ages—Development of Bird.*—So, if we go back in thought to the origin of the race, as we can by actual observation to that of the individual, the old conception of "design" which was based on the idea of an original bird-creation does not lose any of its applicability, if we find reason to believe that the original progenitor was a protoplasmic "jelly-speck," certain of whose descendants have passed through a series of forms progressively improving in structure and capacity, and culminating in the perfected bird. We merely substitute for the idea of continuous uniform descent, that of the "progressive development" of the race, as representing the mode in which our present bird has come to be; deeming the latter the more probable, because we find it correspond with the embryonic history of every bird now existing. The original progenitor was just as "potentially" the race, whether called into existence as a protoplasmic "jelly-speck," or as a fully developed bird. And the evidences of "design," which on the doctrine of "special creations" we find in the construction of the original bird, and in the provision for the continuous propagation of its own type, we equally find in the production of the original "jelly-speck," and in the evolutionary process by which the very lowest type of organization has been progressively elevated to one of the highest. The marvelous succession of changes by which a chick is evolved from the germ-spot of the fowl's egg in the short period of two-and-twenty days assuredly does not become less worthy of our admiration if looked at as the abbreviated repetition of one which has extended continuously over millions of years.—CARPENTER *Nature and Man*, lect. 15, p. 432. (A., 1889.)

786. DESIGN IN NATURE—*Difficulties Unsolvable when We Attribute Our Thoughts to God—Limits of Human Intelligence (Is. lv, 8-9).*—We do not only acknowledge the impossibility of grasping the management of this divine wisdom on our part, but we also gladly acknowledge that when we speak of divine wisdom, of reason in Nature, of having an end in view, of a world-plan, or of an object in the world's development, we are speaking in human terms of that which, after all, is high above everything human, that we are anthropomorphizing. Whether we speak of what is conformable to a design or the part of a highest reason, or of a divine wisdom in Nature, we are in both instances speaking according to human intuitions and power of thought, of that of which we have no corresponding form, have absolutely no analogy. And he who thinks of the divine wisdom as so human that it first decides upon an object and an aim and then makes a plan, and afterwards considers the means for the attainment of this aim, and finally applies the required means, is dragging the power of the Eternal down within the limits and the changes of time. Or he who represents to himself God's management as if he were enthroned in some high place from whence he invades the world for specific purposes, now here, now there, in order to remove some disturbance, or to repair something that human beings have spoiled, he who draws the Infinite Spirit into the limits of space gets himself involved in unsolvable difficulties, into contradictions from which there is no escape.—GRAUE *Darwinismus und Sittlichkeit*, p. 65, in *Deutsche Zeit- und Streit-Fragen*, vol. viii. p. 505. (Translated for *Scientific Side-Lights.*)

787. DESIGN IN THE SEA-ANEMONE—*Coordination of Parts for Result.*—Look, for example, at a sea-anemone in the act of feeding, and see how its multiple tentacles attach themselves to a piece of fish, or to the shell of a mussel or periwinkle, and draw it by their united contraction into the creature's stomach. The adaptation is not less perfect because the action is so simple; nothing could be conceived more suitable to the conditions under which the sea-anemone lives; and the multiplication of similar parts so disposed as to enable them to work together to a common end seems to me as clear an evidence of "designed" adaptation in the sea-anemone as it is admitted to be in the "flint implement" [see DESIGN PROVES DESIGNER, 789-90].—CARPENTER *Nature and Man*, lect. 15, p. 421. (A., 1889.)

788. DESIGN IN WORK OF MEN OR BEAVERS—*Evidence of Purpose in Higher or Lower Mind.*—A dam across a stream, and the appearance of the stumps of trees which entered into its formation, would suggest design quite irrespective of and antecedent to the considerable knowledge or experience which would enable the beholder to decide whether this was the work of men or of beavers. Why, then, should the judgment that any particular structure is a designed work be thought illegitimate when attributed to a higher instead of a lower intelligence than that of man?—GRAY *Darwiniana*, art. 13, p. 364. (A., 1889.)

789. DESIGN PROVES DESIGNER—*Flint Implements—Accident Once Assigned as Their Cause—Human Origin Now Unquestioned.*—About thirty years ago [*i. e.*,

1854] we began to hear a good deal about "flint implements." They had not been altogether unknown previously, as specimens of them were to be found in museums of antiquities; but they had never been brought to light in such numbers, and under such very peculiar circumstances, as in the working of the gravel-beds of the valley of the Somme, near Abbeville and Amiens. The matter was brought into notice by M. Boucher de Perthes, a distinguished antiquarian and collector at Abbeville. English men of science went over to study the conditions under which these flint implements were found, and very soon satisfied themselves of the genuineness and importance of this discovery. There were many who at first denied that they afforded any evidence of the existence of man at the time when these gravel-beds were deposited, maintaining that their peculiar shapes had been given by accidental collisions. I do not know that any sane man now questions their human production.—CARPENTER *Nature and Man*, lect. 15, p. 416. (A., 1889.)

790. ——— ——— *Cumulative Evidence of Human Handiwork.*—If, in walking through a chalk country, you look at a heap of flints collected by the roadside for mending the road, you will find the greater part of them entire, having shapes that suggest to the naturalist the forms of the sponges, by the silicification of which they were originally produced. You will doubtless find some broken; but you will never meet with one that even remotely resembles the characteristic "flint implement" of the Amiens and Abbeville gravels. They may have one or two, or perhaps half a dozen, fractured surfaces; but these are quite irregular, having no relation one to another. Now, a "flint implement" exhibits, perhaps, fifty fractures, and they are all so related in size and position as to bring out a very definite shape. Yet this consideration alone did not by any means satisfy those who were unwilling to admit the conclusion that this shape had been worked out by human hands. I well remember that when these objects were first brought into public notice there were many persons who said, "The shaping of these flints is merely accidental: the flint fell into a river in which there were many stones knocking about, and the fractures have been produced by the flint having got, so to speak, under a number of hammers; so that, a bit having been broken away here and a bit there, it has come to be shaped as it is now found." I will not say that this is an absolutely impossible supposition with respect to any single example: but when we find numbers of these flints, all showing the same form, in one gravel-bed—when we meet with forms exactly similar in other gravel-beds—and when we learn that exactly similar flints are used at the present time by peoples (some of the hill tribes of India, for instance) among whom iron implements have not yet found their way, the implements being held in a cleft stick and bound round by a leather thong—then, I think, we have an accumulation of evidence which makes it inconceivable that these gravel-flints, of which I have spoken, owed their shape to anything else than human handiwork.—CARPENTER *Nature and Man*, lect. 15, p. 417. (A., 1889.)

791. DESIRE OF WEALTH APPROVED—*Modern in Contrast to Ancient Systems.*—Since the dissolution of the Greek and Roman commonwealths, no nation has acted on the one great error of all the ancient systems of political philosophy—that the natural desire of men for the accumulation of wealth is an evil to be dreaded and repressed. So far as this goes there is a sharp and striking contrast between the spirit of ancient and of modern policy. The great object of the ancient policy, says Dugald Stewart, "was to counteract the love of money and a taste for luxury by positive institutions, and to maintain in the great body of the people habits of frugality and a severity of manners. The decline of states is uniformly ascribed by philosophers and historians, both of Greece and Rome, to the influence of riches on national character, and the laws of Lycurgus, which, during a course of ages, banished the precious metals from Sparta, are proposed by many of them as the most perfect model of legislation devised by human wisdom. How opposite to this is the doctrine of modern politicians! Far from considering poverty as an advantage to a state, their great aim is to open new sources of national opulence, and to animate the activity of all classes of the people by a taste for the comforts and accommodations of life."—ARGYLL *Reign of Law*, ch. 7, p. 199. (Burt.)

792. DESTRUCTION, AGENTS OF——*Putrefaction an Impossibility without Bacteria.*—"No putrefaction," says Cohn ["Beiträge zur Biologie der Pflanzen," zweites Heft, 1872, p. 203], "can occur in a nitrogenous substance if it be kept free from the entrance of new bacteria after those which it may contain have been destroyed. Putrefaction begins as soon as bacteria, even in the smallest numbers, are accidentally or purposely introduced. It progresses in direct proportion to the multiplication of the bacteria; it is retarded when the bacteria (for example, by a low temperature) develop a small amount of vitality, and is brought to an end by all influences which either stop the development of the bacteria or kill them. All bactericidal media are therefore antiseptic and disinfecting."—TYNDALL *Floating Matter of the Air*, essay 2, p. 48. (A., 1895.)

793. DESTRUCTION BY INDIRECT ACTION—*Climate and Garden Plants.*—That climate acts in main part indirectly by favoring other species we clearly see in the prodigious number of plants which in our

gardens can perfectly well endure our climate, but which never become naturalized, for they cannot compete with our native plants nor resist destruction by our native animals.—DARWIN *Origin of Species*, ch. 1, p. 65. (Burt.)

794. DESTRUCTION BY MEANS USED FOR SAFETY—*Sleep Changed to Sudden Death—Mountain Flung Down upon Plain.*—The destruction of the Prince of Scilla and a great number of his vassals was one of the most remarkable events attending [the earthquake in Calabria, 1783]. He had persuaded his servants to seek their fishing-boats for safety, and went with them to encourage them. During the night of February 5, while they were sleeping, an enormous mass of earth was flung from Mount Jaci upon the plain near which the boats were moored. Immediately the sea rose more than twenty feet above the level of the plain. Every boat was sunk or dashed upon the beach, and hundreds of persons who had been sleeping on the plain were swept out to sea. The prince and 1,430 of his servants perished.—PROCTOR *Notes on Earthquakes*, p. 4. (Hum., 1887.)

795. DESTRUCTION OF AMERICA'S FORESTS—*Exhaustion of England's Coal—Sun's Direct Heat May Be Reliance of the Future.*—Your mighty forests seem capable of supplying all the timber that the whole race of man could need for ages; yet a very moderate computation of the rate at which they are being cut down, and will presumably continue to be, by a population increasing rapidly in numbers and in the destructive capabilities which characterize modern civilization, would show that America will be denuded of its forest wealth in about the same period which we in England have calculated as probably limiting the effective duration of our stores of coal. That period —a thousand or twelve hundred years—may seem long compared with the life of individual men, long even compared with the duration of any nation in the height of power; but tho men and nations pass away the human race continues, and a thousand years are as less than a day in the history of that race. . . . Either a change in their mode of civilization will be forced on the human race, or else it will then have become possible, as your Ericsson has already suggested, to make the sun's daily heat the mainspring of the machinery of civilization. —PROCTOR *Our Place among Infinities*, p. 26. (L. G. & Co.. 1897.)

796. DESTRUCTION OF ART TREASURES DEPLORED—*Wonders of Life Destroyed without Protest.*—The large avians, together with the finest of the mammalians, will shortly be lost to the pampas utterly, as the great bustard is to England and as the wild turkey and bison and many other species will shortly be lost to North America. What a wail there would be in the world if a sudden destruction were to fall on the accumulated art treasures of the National Gallery, and the marbles in the British Museum, and the contents of the King's Library—the old prints and medieval illuminations! And these are only the work of human hands and brains—impressions of individual genius on perishable material, immortal only in the sense that the silken cocoon of the dead moth is so, because they continue to exist and shine when the artist's hands and brain are dust—and man has the long day of life before him in which to do again things like these, and better than these, if there is any truth in evolution. But the forms of life in the two higher vertebrate classes are Nature's most perfect work; and the life of even a single species is of incalculably greater value to mankind, for what it teaches and would continue to teach, than all the chiseled marbles and painted canvases the world contains.—HUDSON *Naturalist in La Plata*, ch. 1, p. 28. (C. & H., 1895.)

797. DESTRUCTION OF NOXIOUS INSECTS—*Beneficial Industry of Ants.*—There are, of course, many cases in which the action of ants is very beneficial to plants. They kill off a great number of small caterpillars and other insects. Forel found in one large nest that more than twenty-eight dead insects were brought in per minute, which would give during the period of greatest energy more than 100,000 insects destroyed in a day by the inhabitants of one nest alone.—AVEBURY *Ants, Bees, and Wasps*, ch. 3, p. 59. (A., 1900.)

798. DESTRUCTION OF PLANTS BY ANIMALS—Besides this direct competition, there is one not less powerful arising from the exposure of almost all plants to destruction by animals. The buds are destroyed by birds, the leaves by caterpillars, the seeds by weevils; some insects bore into the trunk, others burrow in the twigs and leaves; slugs devour the young seedlings and the tender shoots, wireworms gnaw the roots. Herbivorous mammals devour many species bodily, while some uproot and devour the buried tubers.—WALLACE *Darwinism*, ch. 2, p. 11. (Hum., 1889.)

799. DESTRUCTION OF THE EARTH WOULD BE UNFELT IN UNIVERSE—*Like the Falling of a Leaf in the Forest.*—And what is this world in the immensity which teems with them—and what are they who occupy it? The universe at large would suffer as little, in its splendor and variety, by the destruction of our planet, as the verdure and sublime magnitude of a forest would suffer by the fall of a single leaf. The leaf quivers on the branch which supports it. It lies at the mercy of the slightest accident. A breath of wind tears it from its stem, and it lights on the stream of water which passes underneath. In a moment of time, the life which we know, by the microscope, it teems with, is extinguished; and an occurrence so insignificant in the eye

of man, and on the scale of his observation, carries in it, to the myriads which people this little leaf, an event as terrible and as decisive as the destruction of a world. Now, on the grand scale of the universe, we, the occupiers of this ball, which performs its little round among the suns and the systems that astronomy has unfolded—we may feel the same littleness, and the same insecurity. We differ from the leaf only in this circumstance, that it would require the operation of greater elements to destroy us. But these elements exist.—CHALMERS *Astronomical Discourses*, p. 37. (R. Ct., 1848.)

800. DESTRUCTION OF TREES CHANGES EARTH'S SURFACE—When traveling in Georgia, in 1846, I saw the commencement of hundreds of valleys in places where the native forest had recently been removed. One of these newly formed gullies or ravines . . . occurs on the road to Macon. Twenty years ago, before the land was cleared, it had no existence; but when the trees of the forest were cut down, cracks three feet deep were caused by the sun's heat in the clay; and, during the rains, a sudden rush of water through the principal crack deepened it at its lower extremity, from whence the excavating power worked backwards, till, in the course of twenty years, a chasm, measuring no less than 55 feet in depth, 300 yards in length, and varying in width from 20 to 180 feet, was the result. The highroad has been several times turned to avoid this cavity, the enlargement of which is still proceeding, and the old line of road may be seen to have held its course directly over what is now the wildest part of the ravine.—LYELL *Principles of Geology*, ch. 14, p. 204. (A., 1854.)

801. DESTRUCTION, VIEWLESS AGENT OF—*Frost Disintegrates Rocks and Breaks Down Mountains.*—The disintegrating action of rain in temperate and high latitudes is greatly aided by frost, and the same is the case in the elevated tracts of more southern latitudes. Rain renders the superficial portions of rock more porous, and thus enables frost to act more effectually; while frost, by widening pores and fissures, affords readier ingress to meteoric water. . . . The great heaps or "screes" of rock-rubbish which cloak the summits and slopes of our mountains, and gather thickly along the base of precipice and cliff, have been dislodged by frost and rolled down from above, their progress downward being often aided by torrential rains, melting snow, and the alternate freezing and thawing of the saturated débris itself.—GEIKIE *Earth Sculpture*, ch. 2, p. 28. (G. P. P., 1898.)

802. DEVELOPMENT DELAYED FOR A PURPOSE—*Device to Secure Cross-fertilization.*—In *Spiranthes* the young flowers, which have their pollinia in the best state for removal, cannot possibly be fertilized; they must remain in a virgin condition until they are a little older and the column has moved away from the labellum. Here the same end is gained by widely different means. The stigmas of the older flowers are more adhesive than those of the younger flowers. These latter have their pollinia ready for removal; but immediately after the rostellum has exploded it curls forwards and downwards, thus protecting the stigma for a time; but it slowly becomes straight again, and now the mature stigma is left freely exposed, ready to be fertilized [by pollen from another flower].—DARWIN *Fertilization of Orchids*, ch. 4, p. 121. (A., 1898.)

803. DEVELOPMENT FROM THE CELL—*Embryos of a Sheep, Tiger, Lizard, Bird, and Ape Indistinguishable—Each Animal Recapitulates the History of Its Race.*—Every animal or plant begins its existence as a cell, which develops by a process of repeated fission and growth into the perfect form. But if we trace the different types backward, we find that we come to a stage when the embryos of all the members of an order, such as the various species of ruminants, are indistinguishable; earlier still all the members of a class, such as the mammalia, are equally alike, so that the embryos of a sheep and a tiger would be almost identical; earlier still all vertebrates, a lizard, a bird, and a monkey, are equally indistinguishable. Thus in its progress from the cell to the perfect form every animal recapitulates, as it were, the lower forms upon its line of descent, thus affording one of the strongest indirect proofs of the theory of evolution. The earliest definite result of cell-division is to form what is termed the "gastrula," which is a sac with a narrow mouth, formed of two layers of cells. All the higher animals, without exception, from mollusk to man, go through this "gastrula" stage, which again indicates that all are descended from a common ancestral form of this general type.—WALLACE *The Wonderful Century*, ch. 14, p. 144. (D. M. & Co., 1899.)

804. DEVELOPMENT, GRADUAL—*Of Arts and Sciences—Antiquity of Egyptian and Babylonian Culture.*—On the whole it appears that wherever there are found elaborate arts, abstruse knowledge, complex institutions, these are results of gradual development from an earlier, simpler, and ruder state of life. No stage of civilization comes into existence spontaneously, but grows or is developed out of the stage before it. This is the great principle which every scholar must lay firm hold of, if he intends to understand either the world he lives in or the history of the past. Let us now see how this bears on the antiquity and early condition of mankind. The monuments of Egypt and Babylonia show that toward 5,000 years ago certain nations had already come to an advanced state of culture. No doubt the greater part of the earth was then

peopled by barbarians and savages, as it remained afterwards. But in the regions of the Nile and the Euphrates there was civilization.—Tylor *Anthropology,* ch. 1, p. 20. (A., 1899.)

805. ——— ——— *Of Culture through the Ages.*—Within the entire economy of the human race on earth, it has been found that just that which had its origin in physical needs, on further development serves ideal purposes. But before this distillation of spirit out of naturalism can take place, centuries, thousands of years, must elapse, as we observe from the history of culture in the Orient, or may perceive in any peasant village.—Humboldt, *quoted by* Goltz, *Ethnologische Studie zur Geschichte und Charakterisirung des deutschen Volkes,* p. 130. (Translated for *Scientific Side-Lights.)*

806. DEVELOPMENT MAY BE RETROGRESSIVE—*Nature Discards the Most Elaborate Structures when Disused.*—Everything that Nature has built up with such elaborate care—highly developed organs of locomotion, limbs fitted to support a certain weight, joints with their complex and yet easy movements, the exquisite balance of muscular strength required for rapid motion on the ground, wings adapted for flying, with all the marvelously adjusted organs which overcome gravity and render rising into the air a possibility, every one of the adaptations by which animals are placed in communication with the outer world which surrounds them—eyes of the most delicate and complex structure, organs of hearing and smell so wonderfully formed that it has needed long years of the combined researches of all the most eminent naturalists to understand their full significance—each one of these is relinquished, is handed over to a process of gradual destruction, the moment it ceases to be essential to the life of the species.—Weismann *Heredity,* vol. ii, ch. 9, p. 29. (Cl. P., 1897.)

807. DEVELOPMENT OF EXPERIMENTAL SCIENCE—*Greek Study Too Subjective.*—The knowledge of Nature, as it existed among the Hellenic nations under the most ancient forms of physics, was derived more from the depth of mental contemplation than from the sensuous consideration of phenomena. Thus the natural philosophy of the Ionian physiologists was directed to the fundamental ground of origin, and to the metamorphoses of one sole element, while the mathematical symbolism of the Pythagoreans, and their consideration of numbers and forms, disclose a philosophy of measure and harmony. The Doric-Italian school, by its constant search for numerical elements, and by a certain predilection for the numerical relations of space and time, laid the foundation, as it were, of the subsequent development of our experimental sciences.—Humboldt *Cosmos,* vol. ii, pt. ii, p. 108. (H., 1897.)

808. DEVELOPMENT OF INDIVIDUAL REPEATS THAT OF RACE—The history of the development of the individual is a repetition of the history of the race. That is to say, each organic being in its development repeats in brief the entire process the ancestors of the individual have passed through from the origin of the race.—Vaihinger, an address. (Translated for *Scientific Side-Lights.)*

809. DEVELOPMENT OF REPTILE INTO BIRD — *Aimless Variation Not an Explanation—Intentional Prearrangement Necessary.*—Let us grant, for the sake of argument, that all past and present modifications of the original bird type may have thus arisen [*i. e.,* by "natural selection"]. But on the mode in which that singularly specialized type came into existence—in which that most wonderful feature of its organization, the feather, arose out of the scaly covering of its reptilian ancestors—in which its heart came to be divided into four chambers instead of three, and the arrangement of its blood-vessels altered accordingly, in the establishment of the "complete double circulation," that insures the perfect aeration of the blood needed for the maintenance of the extraordinary muscular energy by which the feathered wings can sustain the body in flight—I cannot see that "natural selection" throws the least light. There is, as I have already pointed out, an adaptation in the several parts of the structure of the bird, not only to one general result, but to a consentaneous action in bringing about that result, which shows itself to be more complete the more closely it is scrutinized. And on the hypothesis of "natural selection" among "aimless" variations, I think it could be shown that the probability is infinitely small, that the progressive modifications required in the structure of each individual organ to convert a reptile into a bird, could have taken place without disturbing the required harmony in their combined action; nothing but intentional prearrangement being competent to bring about such a result. And the point on which I now wish to fix your attention is the evidence of such prearrangement that is furnished by the orderly sequence of variations allowing definite lines of advance.—Carpenter *Nature and Man,* lect. 15, p. 441. (A., 1889.)

810. DEVELOPMENT OF SCIENCE—*Advances Made in Astronomy—Earth Closer to Other Worlds.*—We stand in a position much more favorable for the formation of just views on the subject of life in other worlds than that from which men surveyed the planetary and stellar systems thirty or forty years since. Never, since men first explored the celestial depths, has a series of more startling discoveries rewarded the labors of astronomers and physicists than during the past few years. Unhoped-for revelations have been made on every side.

Analogies the most interesting have brought the distant orbs of heaven into close relationship with our own earth or with the central luminary of the planetary scheme. And a lesson has been taught us which bears even more significantly on our views respecting the existence of other worlds: we have learned to recognize within the solar system, and within the wondrous galaxy of which our sun is a constituent orb, a variety of structure and a complexity of detail of which but a few years ago astronomers had formed but the most inadequate conceptions. —PROCTOR *Other Worlds than Ours*, int., p. 19. (Burt.)

811. ——— ——— *Astronomy Historically the First of the Sciences—Next, Mechanics.*—For a time—and that historically a long one—he [man] was limited to mere observation, accepting what Nature offered, and confining intellectual action to it alone. The apparent motions of sun and stars first drew towards them the questionings of the intellect, and accordingly astronomy was the first science developed. Slowly, and with difficulty, the notion of natural forces took root in the human mind. Slowly, and with difficulty, the science of mechanics had to grow out of this notion; and slowly at last came the full application of mechanical principles to the motions of the heavenly bodies. We trace the progress of astronomy through Hipparchus and Ptolemy; and, after a long halt, through Copernicus, Galileo, Tycho Brahe, and Kepler; while from the high table-land of thought raised by these men Newton shoots upward like a peak, overlooking all others from his dominant elevation.—TYNDALL *Lectures on Light*, lect. 1, p. 4. (A., 1898.)

812. DEVELOPMENT OF SENSES AS WELL AS MUSCLES BY PRACTISE—*Possible Discrimination of Minute Differences of Sensation.*—That "practise makes perfect" is notorious in the field of motor accomplishments. But motor accomplishments depend in part on sensory discrimination. Billiard-playing, rifle-shooting, tight-rope-dancing, demand the most delicate appreciation of minute disparities of sensation, as well as the power to make accurately graduated muscular response thereto. In the purely sensorial field we have the well-known virtuosity displayed by the professional buyers and testers of various kinds of goods. One man will distinguish by taste between the upper and the lower half of a bottle of old Madeira. Another will recognize, by feeling the flour in a barrel, whether the wheat was grown in Iowa or Tennessee. The blind deaf-mute, Laura Bridgman, had so improved her touch as to recognize, after a year's interval, the hand of a person who once had shaken hers; and her sister in misfortune, Julia Brace, is said to have been employed in the Hartford Asylum to sort the linen of its multitudinous inmates, after it came from the wash, by her wonderfully educated sense of smell.—JAMES *Psychology*, vol. i, ch. 13, p. 509. (H. H. & Co., 1899.)

813. DEVELOPMENT, ORDERLY, OF UNIVERSE—*Astronomy, Geology, Zoology Allied—One Grand Movement Pervading All Sciences.*—It was not until the nineteenth century that the microscope . . . was perfected as an instrument, and accomplished for zoology its final and most important service. . . .

On the other hand, the astronomical theories of development of the solar system from a gaseous condition to its present form, put forward by Kant and by Laplace, had impressed men's minds with the conception of a general movement of spontaneous progress or development in all Nature; and, tho such ideas were not new, but are to be found in some of the ancient Greek philosophers, yet now for the first time they could be considered with a sufficient knowledge and certainty as to the facts, due to the careful observation of the two preceding centuries. The science of geology came into existence, and the whole panorama of successive stages of the earth's history, each with its distinct population of strange animals and plants, unlike those of the present day and simpler in proportion as they recede into the past, was revealed by Cuvier, Agassiz, and others. The history of the crust of the earth was explained by Lyell as due to a process of slow development, in order to effect which he called in no cataclysmal agencies, no mysterious forces differing from those operating at the present day. Thus he carried on the narrative of orderly development from the point at which it was left by Kant and Laplace—explaining by reference to the ascertained laws of physics and chemistry the configuration of the earth, its mountains and seas, its igneous and its stratified rocks, just as the astronomers had explained by those same laws the evolution of the sun and planets from diffused gaseous matter of high temperature.

The suggestion that living things must also be included in this great development was obvious.—LANKESTER *History and Scope of Zoology*, p. 7. (Hum., 1893.)

814. DEVELOPMENT, PSYCHICAL, ARRESTS PHYSICAL—*Future Progress within the Mind, Not the Body.*—Alfred Russel Wallace, the illustrious codiscoverer of natural selection, saw that along with the general development of mammalian intelligence a point must have been reached in the history of one of the primates when variations of intelligence were more profitable to him than variations in body. From that time forth that primate's intelligence went on by slow increments acquiring new capacity, while his body changed but little. When once he could strike fire, and chip a flint, and use a club, and strip off the bear's hide to cover himself, there was clearly no further use in thickening his own hide, or lengthen-

ing and sharpening his claws. Natural selection is the keenest capitalist in the universe; she never loses an instant in seizing the most profitable place for investment, and her judgment is never at fault.—FISKE *Through Nature to God,* pt. ii, ch. 5, p. 83. (H. M. & Co., 1900.)

815. DEVIATIONS INHERITABLE—The number and diversity of inheritable deviations of structure, both those of slight and those of considerable physiological importance, are endless. Dr. Prosper Lucas's treatise, in two large volumes, is the fullest and the best on this subject. No breeder doubts how strong is the tendency to inheritance; that like produces like is his fundamental belief: doubts have been thrown on this principle only by theoretical writers. [See HEREDITY OF ACQUIRED CHARACTERS.]—DARWIN *Origin of Species,* ch. 1, p. 12. (Burt.)

816. DEVICE COMMON TO DIVERSE PEOPLES—*Falcons of the Sea—A Sucking-fish as Captor of Other Fishes.*—In the time of Columbus the now desolate district of the Jardines del Rey was animated by a singular branch of industry pursued by the inhabitants of the seacoasts of Cuba, who availed themselves of a little fish, the remora, or sucking-fish (the so-called ship-holder), probably the *Echeneis naucrates,* for catching turtles. A long and strong line, made of the fibers of the palm, was attached to the tail of the fish. The remora (called in Spanish *revcs,* or reversed, because at first sight the back and abdomen might easily be mistaken for each other) attaches itself by suction to the turtle through the indented and movable cartilaginous plates of the upper shell that covers the head. The remora, says Columbus, would rather let itself be torn to pieces than relinquish its prey, and the little fish and the turtle are thus drawn out of the water together. . . . We learn from Dampier and Commerson that this artifice of employing a sucking-fish to catch other fishes is very common on the eastern coasts of Africa, near Cape Natal and Mozambique, as well as on the island of Madagascar. An acquaintance with the habits of animals, and the same necessities, lead to similar artifices and modes of capture amongst tribes having no connection with one another.—HUMBOLDT *Views of Nature,* p. 257. (Bell, 1896.)

817. DEVICES FOR EXPLAINING THE MYSTERY OF EVIL—*Comte Would Have Improved the Tilt of the Earth's Axis.*—[To explain the mystery of evil] it has usually been found necessary to represent the Creator as finite either in power or in goodness, altho the limitation is seldom avowed, except by writers who have a leaning toward atheism and take a grim pleasure in pointing out flaws in the constitution of things. Among modern writers the most conspicuous instance of this temper is afforded by that much too positive philosopher, Auguste Comte, who would fain have tipped the earth's axis at a different angle and altered the arrangements of Nature in many fanciful ways. He was like Alphonso, the learned king of Castile, who regretted that he had not been present when the world was created—he could have given such excellent advice!—FISKE *Through Nature to God,* pt. i, ch. 3, p. 12. (H. M. & Co., 1900.)

818. DEVOTION TO SCIENCE—*Von Buch Traverses Europe on Foot for Geologic Study—Unites the Aqueous and Igneous Theories.*—It was a pupil of Werner's who at last set at rest this much-vexed question [between the aqueous and the igneous origin of rocks].

At the age of sixteen, in the year 1790, Leopold von Buch was placed under Werner's care at the mining school of Freiberg. . . . Von Buch was indefatigable. For years he lived the life of an itinerant geologist. With a shirt and a pair of stockings in his pocket, and a geological hammer in his hand, he traveled all over Europe on foot. The results of his foot-journey to Scandinavia were among his most important contributions to geology. He went also to the Canary Islands; and it is in his extensive work on the geological formations of these islands that he showed conclusively not only the Plutonic character of all unstratified rocks, but also that to their action upon the stratified deposits the inequalities of the earth's surface are chiefly due. He first demonstrated that the melted masses within the earth had upheaved the materials deposited in layers upon its surface, and had thus formed the mountains.—AGASSIZ *Geological Sketches,* ser. i, ch. 4, p. 111. (H. M. & Co., 1896.)

819. DEW, FORMATION OF—*Nice Balance of Atmospheric Moisture and Temperature Provided for.*—Dew forms more readily and more abundantly on grass, on account of the numerous centers of condensation it affords. Dew, however, is now formed only on clear cold nights after warm or moist days. The air near the surface is warm and contains much vapor, tho below the point of saturation. But the innumerable points and extensive surfaces of grass radiate heat quickly, and becoming cool, lower the temperature of the adjacent air, which then reaches saturation-point and condenses the contained vapor on the grass. Hence, if the atmosphere at the earth's surface became supersaturated with aqueous vapor, dew would be continuously deposited, especially on every form of vegetation, the result being that everything, including our clothing, would be constantly dripping wet. If there were absolutely no particles of solid matter in the upper atmosphere, all the moisture would be returned to the earth in the form of dense mists, and frequent and

copious dews, which in forests would form torrents of rain by the rapid condensation on the leaves.—WALLACE *The Wonderful Century,* ch. 9, p. 78. (D. M. & Co., 1899.)

820. DIFFERENCE IN HABITS OF MALE AND FEMALE—*Mother-bird Seeks Protection in Silence.*—A scarlet-breasted troopial of La Plata perches conspicuously on a tall plant in a field, and at intervals soars up vertically, singing, and, at the highest ascending point, flight and song end in a kind of aerial somersault and vocal flourish at the same moment. Meanwhile, the dull-plumaged female is not seen and not heard: for not even a skulking crake lives in closer seclusion under the herbage—so widely have the sexes diverged in this species. Is the female, then, without an instinct so common?—has she no sudden fits of irrepressible gladness? Doubtless she has them, and manifests them down in her place of concealment in lively chirpings and quick motions—the simple, primitive form in which gladness is expressed in the class of birds. In the various species of the genus *Cnipolegus* . . . the difference in the sexes is just as great as in the case of the troopial; the solitary, intensely black, statuesque male has . . . a set and highly fantastic performance; but on more than one occasion I have seen four or five females of one species meet together and have a little simple performance all to themselves—in form a kind of lively mock-fight.—HUDSON *Naturalist in La Plata,* ch. 19, p. 283. (C. & H., 1895.)

821. DIFFERENCE IN WEARING OF ROCKS BY ICE AND BY WATER—*Nature's Distinctions also Those of Science.*—The leveling and abrading action of water on rock has an entirely different character [from glacier action]. Tides or currents driven powerfully and constantly against a rocky shore, and bringing with them hard materials, may produce blunt, smooth surfaces, such as the repeated blows of a hammer on stone would cause; but they never bring it to a high polish, because the grinding materials are not held steadily down in firm permanent contact with the rocky surfaces against which they move, as is the case with the glacier. On the contrary, being dashed to and fro, they strike and rebound, making a succession of blows, and never a continuous, uninterrupted pressure and friction. The same is true of all the marks made on rocky shores against which loose materials are driven by water-currents. They are separate, disconnected, fragmentary; whereas the lines drawn by the hard materials set in the glacier, whether light and fine or strong and deep, are continuous, often unbroken for long distances and rectilinear.—AGASSIZ *Geological Sketches,* ser. ii, p. 35. (H. M. & Co., 1896.)

822. DIFFERENCE OF DEVELOPMENT PRODUCES DIFFERENCE OF CHARACTER—*Among Bees, Workers Are But Undeveloped Queens.*—The "workers" among hive-bees are not really "neuters," but are undeveloped females; every one of them being originally a potential queen. They differ from the queen, or fertile female, however, not merely in the non-development of the reproductive organs (which shows itself in the inferior length of the abdomen), but also in the possession of the "pollen-baskets" on the thighs, which are used in the collection of pollen and propolis, and in the conformation of the jaws and antennæ. But they differ yet more in their instincts, for whilst the life-work of the queen is to lay eggs, that of the workers is to build cells for their reception, to collect and store up food, and to nurture the larvæ—this nurturing process being continued as a sort of incubation during the pupa-state. The worker-larvæ, which come forth from the eggs that are laid in ordinary cells, are fed for three days upon a peculiar substance of jellylike appearance, prepared in the stomachs of the workers; but afterwards upon "bee-bread" composed of a mixture of honey and pollen. The queen-larvæ, on the other hand, are reared in larger royal cells of peculiar construction; and they are fed during the whole of the larva-period upon the substance prepared by the workers, which is hence known as "royal jelly." The length of time occupied in their development is different; the preliminary stages of the queen being passed through in sixteen days, whilst those of the worker require twenty-one.

Now it sometimes happens that, from some causes not understood, there is a failure in the production of young queens, so that there are none forthcoming when wanted. The workers then select either worker-eggs or worker-larvæ not yet three days old, and around these they construct "royal cells," by throwing together several adjacent worker-cells and destroying the larvæ they contain. The selected larvæ are fed with the "royal jelly," and are treated in every respect as queen-larvæ; and in due time they come forth as perfect queens—thus having had not only their bodily organization, but their psychical nature, essentially altered by the nurture they have received.—CARPENTER *Mental Physiology,* ch. 2, p. 61. (A., 1900.)

823. DIFFERENCE OF QUANTITY, NOT OF QUALITY—*Similarity of Feeble and Violent Volcanic Eruptions.*—We are thus led to the conclusion that the grand and terrible appearances displayed at Vesuvius and other volcanoes in a state of violent eruption do not differ in any essential respect from the phenomena which we have witnessed accompanying the miniature outbursts of Stromboli. And we are convinced, by the same considerations, that the forces which give rise to the feeble displays in the latter case would produce, if acting with greater intensity and violence, all the magnificent spectacles presented in the former. In Vesuvius and Stromboli alike, the active

cause of all the phenomena exhibited is found to be the escape of steam from the midst of masses of incandescent liquefied rock. The violence, and therefore the grandeur and destructive effects, of an eruption depend upon the abundance and tension of this escaping steam.—JUDD *Volcanoes*, ch. 2, p. 31. (A., 1899.)

824. DIFFERENCES, ABSOLUTE AND RELATIVE—*Moonlight vs. Sunlight—Darkening Shadow Has the Effect of Increasing Light.*—If we compare the shadow thrown by an object in moonlight with the shadow cast by the same object in sunlight, it will be at once seen that the former appears much darker than the latter. In a landscape seen by moonlight, this stronger contrast of light and shade makes the illumination far brighter, altho it is absolutely much less intense. And from this fact we can distinguish at the first glance whether a picture represents a moonlight or a daylight scene. It is not in the power of the artist to mark this difference by an absolute difference of light-intensity. Both his paintings are equally bright; but he makes the difference between light and shadow greater in the first picture than in the second, and by this single device enables us to distinguish in a moment the night scene from the day scene.—WUNDT *Psychology*, lect. 4, p. 58. (Son. & Co., 1896.)

825. DIFFERENCES AMONG ANIMALS IN THE PHILIPPINES—Supposing that a long chain of islands had connected two lands lying far apart and differing widely in their fauna, it might be expected, and with great probability, that the fauna of this group could have retained no special homogeneous character. For the vicinity of the two terminal countries, and the currents probably existing, might easily have caused on the islands a mixture of the two dissimilar faunas. This is, in fact, sometimes the case. The Philippines lie very nearly north and south; the northern islands are connected with China by the Bashees and Formosa, while the southernmost island, Mindanao, is connected by Celebes and some smaller islands with the Moluccas, and the southwestern island, Palawan, hangs on to Borneo by Balabac. . . . A greater contrast can hardly be conceived of than that, for instance, between the fauna of Hongkong, Amoy, or even Siam, on one side, and Borneo, Java, and Sumatra, on the other. And this difference is repeated in a very striking manner in the Philippines, where the northern district displays an unmistakable harmony with the true Chinese fauna, while the southern islands show a marked resemblance partly to Borneo, partly to Celebes and Gilolo, and partly to the western islands of the Australian region.—SEMPER *Animal Life*, ch. 9, p. 283. (A., 1881.)

826. DIFFERENCES BETWEEN MAN AND APE—*An Unbridged Chasm—No Intermediate Link.*—Thus, whatever system of organs be studied, the comparison of their modifications in the ape series leads to one and the same result—that the structural differences which separate man from the gorilla and the chimpanzee are not so great as those which separate the gorilla from the lower apes.

But in enunciating this important truth, I must guard myself against a form of misunderstanding which is very prevalent. I find, in fact, that those who endeavor to teach what Nature so clearly shows us in this matter are liable to have their opinions misrepresented and their phraseology garbled until they seem to say that the structural differences between man and even the highest apes are small and insignificant. Let me take this opportunity, then, of distinctly asserting, on the contrary, that they are great and significant; that every bone of a gorilla bears marks by which it might be distinguished from the corresponding bone of a man; and that, in the present creation, at any rate, no intermediate link bridges over the gap between homo and troglodytes.

It would be no less wrong than absurd to deny the existence of this chasm; but it is at least equally wrong and absurd to exaggerate its magnitude, and, resting on the admitted fact of its existence, to refuse to inquire whether it is wide or narrow.—HUXLEY *Man's Place in Nature*, p. 232. (Hum.)

827. DIFFERENCES OF INSTRUMENTS FOR STUDY OF THE HEAVENS—*The Transit Instrument and the Equatorial—Each Has Its Own Special Value—Analogy of Spiritual Gifts (1 Cor. xiii, 4-6; Rom. xii, 6-9).*—There are two chief modes of using the telescope, to which all others may be considered subordinate. Either it may be invariably directed towards the south, with no motion save in the plane of the meridian, so as to intercept the heavenly bodies at the moment of transit across that plane; or it may be arranged so as to follow the daily revolution of the sky, thus keeping the object viewed permanently in sight, instead of simply noting the instant of its flitting across the telescopic field. The first plan is that of the "transit instrument," the second that of the "equatorial." . . .

The uses of each are entirely different. With the transit, the really fundamental task of astronomy—the determination of the movements of the heavenly bodies—is mainly accomplished; while the investigation of their nature and peculiarities is best conducted with the equatorial. One is the instrument of mathematical the other of descriptive astronomy. One furnishes the materials with which theories are constructed, and the tests by which they are corrected; the other registers new facts, takes note of new appearances, sounds the depths and pries into every nook of the heavens.—CLERKE *History of Astronomy*, pt. i, ch. 6, p. 149. (Bl., 1893.)

828. DIFFICULTIES IMPOSED UPON RELIGION—*Supernatural Power Not Denied the Use of Means.*—By "supernatural" power, do we not mean power independent of the use of means, as distinguished from power depending on knowledge—even infinite knowledge—of the means proper to be employed? This is the sense—probably the only sense—in which the supernatural is, to many minds, so difficult of belief. No man can have any difficulty in believing that there are natural laws of which he is ignorant; nor in conceiving that there may be beings who do know them, and can use them, even as he himself now uses the few laws with which he is acquainted. The real difficulty lies in the idea of will exercised without the use of means—not in the idea of will exercised through means which are beyond our knowledge, or beyond our reach. Now, have we any right to say that belief in this is essential to all religion? If we have not, then it is only putting, as so many other hasty sayings do put, additional difficulties in the way of religion.—ARGYLL *Reign of Law,* ch. 1, p. 9. (Burt.)

829. DIFFICULTIES WITH THE ETHER—*Seemingly Incompatible Qualities Involved.*—Indeed, I cannot agree with those who regard the wave theory of light as an established principle of science. That it is a theory of the very highest value I freely admit, and that it has been able to predict the phases of unknown phenomena, which experiment has subsequently brought to light, is a well-known fact. All this is true: but then, on the other side, the theory requires a combination of qualities in the ether of space, which I find it difficult to believe are actually realized. For instance, the rapidity with which wave-motion is transmitted depends, other things being equal, on the elasticity of the medium. Assuming that two media have the same density, their elasticities are proportional to the squares of the velocities with which a wave travels. The velocity of the sound-wave in air is about 1,100 feet a second or one-fifth of a mile, that of the light-wave about 192,000 miles a second, or about one million times greater; and, if we take into account certain causes, which, tho they tend to increase the velocity of sound, can have no effect on the luminiferous ether, the difference would be even greater than this. . . . It is a medium so thin that the earth, moving in its orbit 1,100 miles a minute, suffers no perceptible retardation, and yet endowed with an elasticity in proportion to its density a million million times greater than air.—COOKE *New Chemistry,* lect. 1, p. 14. (A., 1899.)

830. DIFFICULTY A SPUR TO ACTION—*Men of Northern Lands Lead the World.*—Notwithstanding the obstacles opposed in northern latitudes to the discovery of the laws of Nature, owing to the excessive complication of phenomena and the perpetual local variations that, in these climates, affect the movements of the atmosphere and the distribution of organic forms, it is to the inhabitants of a small section of the temperate zone that the rest of mankind owe the earliest revelation of an intimate and rational acquaintance with the forces governing the physical world. Moreover, it is from the same zone (which is apparently more favorable to the progress of reason, the softening of manners, and the security of public liberty) that the germs of civilization have been carried to the regions of the tropics, as much by the migratory movement of races as by the establishment of colonies.—HUMBOLDT *Cosmos,* vol. i, int., p. 36. (H., 1897.)

831. DIFFICULTY OF ATTAINING TO TRUE FAMILY LIFE—*Easy Destruction of the Ideal—Without It Nations Perish—The Best Family Life Has Best Promise of Survival.*—With the Christian era the machinery was complete; the circle finally closed in, and became a secluded shrine where the culture of everything holy and beautiful was carried on. The path by which this ideal consummation was reached was not, as we have seen, a straight path; nor has the integrity of the institution been always preserved through the later centuries. The difficulty of realizing the ideal may be judged of by the fewness of the nations now living who have reached it, and by the multitude of peoples and tribes who have vanished from the earth without attaining it. From the failure to fulfil some one or other of the required conditions, people after people and nation after nation have come together only to disperse and leave no legacy behind except the lesson—as yet in few cases understood—of why they failed.

Yet whether the road be straight or devious is of little moment. The one significant thing is that it rises. We have reached a stage in evolution at which physiological gains are guarded and accentuated, if not in an ethical interest, at least by ethical factors becoming utilized by natural selection. Henceforth affection becomes a power in the world; and whatever physiological adjustments continue to go on beneath the surface, the most attached families will have a better chance of surviving and of transmitting their moral characteristics to succeeding generations. The completion of the arch of family life forms one of the great, if not the greatest, of the landmarks of history.—DRUMMOND *Ascent of Man,* ch. 9, p. 315. (J. P., 1900.)

832. DIFFICULTY OF EXPERIMENTAL TESTS ON DEEP-SEA ANIMALS—We cannot judge at all of the amount of light given out by an animal in deep water by its appearance when thrown out of a dredge upon the deck. Whether the phosphorescent light given out by an alcyonarian or a crustacean is more or less at a tem-

perature of 40° F. and a pressure of one ton per square inch than it is at 60° F. and the ordinary barometric pressure of the sea-level is a question that has not yet been brought to an experimental test.

Whatever the answer to this question may be, the fact remains that a greater percentage of animals from the deep sea exhibit some sort of phosphorescent light when brought on deck than animals that live in shallow water.—HICKSON *Fauna of the Deep Sea,* ch. 4, p. 76. (A., 1894.)

833. DIFFICULTY OF OBTAINING KNOWLEDGE OF MANLIKE APES—*Stories Largely Mythical.*—Sound knowledge respecting the habits and mode of life of the manlike apes has been even more difficult of attainment than correct information regarding their structure.

Once in a generation, a Wallace may be found physically, mentally, and morally qualified to wander unscathed through the tropical wilds of America and of Asia, to form magnificent collections as he wanders, and withal to think out sagaciously the conclusions suggested by his collections; but, to the ordinary explorer or collector, the dense forests of equatorial Asia and Africa, which constitute the favorite habitation of the orang, the chimpanzee, and the gorilla, present difficulties of no ordinary magnitude; and the man who risks his life by even a short visit to the malarious shores of those regions may well be excused if he shrinks from facing the dangers of the interior; if he contents himself with stimulating the industry of the better-seasoned natives, and collecting and collating the more or less mythical reports and traditions with which they are too ready to supply him.

In such a manner most of the earlier accounts of the habits of the manlike apes originated; and even now a good deal of what passes current must be admitted to have no very safe foundation. The best information we possess is that based almost wholly on direct European testimony respecting the gibbons; the next best evidence relates to the orangs; while our knowledge of the habits of the chimpanzee and the gorilla stands much in need of support and enlargement by additional testimony from instructed European eye-witnesses.—HUXLEY *Man's Place in Nature,* p. 203. (Hum.)

834. DIFFICULTY OF SOCIOLOGICAL STUDY—*Positivism Would Assign It to a Caste—Possibilities of Persecution in Name of Science.*—In M. Comte's opinion, the peculiarly complicated nature of sociological studies, and the great amount of previous knowledge and intellectual discipline requisite for them, together with the serious consequences that may be produced by even temporary errors on such subjects, render it necessary, in the case of ethics and politics, still more than of mathematics and physics, that whatever legal liberty may exist of questioning and discussing, the opinions of mankind should really be formed for them by an exceedingly small number of minds of the highest class, trained to the task by the most thorough and laborious mental preparation; and that the questioning of their conclusions by any one not of an equivalent grade of intellect and instruction should be accounted equally presumptuous, and more blamable, than the attempts occasionally made by sciolists to refute the Newtonian astronomy. All this is, in a sense, true; but we confess our sympathy with those who feel towards it like the man in the story, who, being asked whether he admitted that six and five make eleven, refused to give an answer until he knew what use was to be made of it.—MILL *Positive Philosophy of Auguste Comte,* p. 70. (H. H. & Co., 1887.)

835. DIFFICULTY OF WIDE-SPREAD REFORMS—*Early Fixedness of Mental States—New Conceptions Rarely Acquired in Later Life.*—Most men begin to be old fogies at the age of twenty-five. It is true that a grown-up adult keeps gaining well into middle age a great knowledge of details, and a great acquaintance with individual cases connected with his profession or business life. In this sense, his conceptions increase during a very long period; for his knowledge grows more extensive and minute. But the larger categories of conception, the sorts of thing, and wider classes of relation between things, of which we take cognizance, are all got into the mind at a comparatively youthful date. Few men ever do acquaint themselves with the principles of a new science after even twenty-five. If you do not study political economy in college, it is a thousand to one that its main conceptions will remain unknown to you through life. Similarly with biology, similarly with electricity. What percentage of persons now fifty years old have any definite conception whatever of a dynamo, or how the trolley-cars are made to run? Surely, a small fraction of one per cent. But the boys in colleges are all acquiring these conceptions.—JAMES *Talks to Teachers,* ch. 14, p. 166. (H. H. & Co., 1900.)

836. DIGESTION OF ANIMAL MATTER BY PLANTS—*Reversal of the Common Order of Nature—Man Cannot Set Boundaries of Possibility.*—As we have seen that nitrogenous fluids act very differently on the leaves of *Drosera* [the sun-dew] from non-nitrogenous fluids, and as the leaves remain clasped for a much longer time over various organic bodies than over inorganic bodies, such as bits of glass, cinder, wood, etc., it becomes an interesting inquiry whether they can only absorb matter already in solution, or render it soluble—that is, have the power of digestion. We shall immediately see that they certainly have this power, and that they act on albuminous compounds in exactly the same manner as does the gastric juice of mammals; the di-

gested matter being afterwards absorbed. This fact, which will be clearly proved, is a wonderful one in the physiology of plants.—DARWIN *Insectivorous Plants*, ch. 6, p. 71. (A., 1900.)

837. DIRECTION, SENSE OF, IN BEES AND WASPS—*Difficulty of Learning by Experience.*—The following are Sir John Lubbock's [Lord Avebury's] observations upon this subject in the case of bees and wasps:

"Every one has heard of a 'bee-line.' It would be no less correct to speak of a wasp-line. On August 6 I marked a wasp, the nest of which was round the corner of the house, so that her direct way home was not out at the window by which she had entered, but in the opposite direction, across the room to a window which was closed. I watched her for some hours, during which time she constantly went to the wrong window, and lost much time in buzzing about at it. For ten consecutive days this wasp paid numerous visits, coming in at the open window, and always trying, tho always unsuccessfully, to return to her nest in the 'wasp-line' of the closed window—buzzing about that window for hours at a time, tho eventually on finding it closed she returned and went round through the open window by which she always entered."

This observation shows how strong must be the instinct in a wasp to take the shortest way home, and how much the insect depends upon its sense of direction in so doing. It also shows how long a time it requires to learn by individual experience the properties of a previously unknown substance, such as glass.—ROMANES *Animal Intelligence*, ch. 4, p. 144. (A., 1899.)

838. DIRECTNESS OF RAYS OF LIGHT—*Ancients Knew the Rectilinear Propagation of Light—Hence the Terms "Ray" and "Beam."*—The ancients were aware of the rectilinear propagation of light. They knew that an opaque body, placed between the eye and a point of light, intercepted the light of the point. Possibly the terms "ray" and "beam" may have been suggested by those straight spokes of light which, in certain states of the atmosphere, dart from the sun at his rising and his setting. The rectilinear propagation of light may be illustrated by permitting the solar light to enter, by a small aperture in a window-shutter, a dark room in which a little smoke has been diffused. In pure air you cannot see the beam, but in smoke you can, because the light, which passes unseen through the air, is scattered and revealed by the smoke particles, among which the beam pursues a straight course.—TYNDALL *Lectures on Light*, lect. 1, p. 9 (A., 1898.)

839. DISASTER LEADS TO DISCOVERY—*Explosiveness of Niter Demonstrated.*—The first published contribution to chemistry [under the auspices of the Smithsonian Institution] was the "Memoir on the Explosiveness of Niter," by Robert Hare. . . . Its history is interesting. A fire occurred in New York City on July 19, 1845, during which two hundred and thirty houses were destroyed, containing merchandise valued at over two millions of dollars. A peculiar feature of this catastrophe was a series of detonations successively increasing in loudness, and followed by a final explosion which tore in pieces the building where it occurred, threw down several houses in the vicinity, and forced in the fronts of houses on the opposite side of the street. These effects were attributed to gunpowder, but the owner of the building declared that he had none of that explosive, altho a large quantity of niter was stored in the house. Dr. Hare showed by numerous experiments that explosions of a violent character could be produced by forcibly bringing in contact at a high temperature niter and substances of an inflammable character.—MARCUS BENJAMIN *Chemistry in the Smithsonian Institution, History of the First Half Century*, p. 612.

840. DISASTER, POSSIBLE, MAN PROVIDES AGAINST—*Houses Built to Withstand Earthquakes.*—In South America, altho many buildings are built with brick and stone, the ordinary houses, and even the larger edifices, are specially built to withstand earthquakes. In Mr. James Douglas's account of a "Journey Along the West Coast of South America," we read the following: "The characteristic building material of Guayaquil is bamboo, which grows to many inches in thickness, and which, when cut partially through longitudinally at distances of an inch or so, and once quite through, can be opened out into fine elastic boards of serviceable width. Houses, and even churches, of a certain primitive beauty are built of such reeds, so bound together with cords that few nails enter into the construction, and which, therefore, yield so readily to the contortions of the earth during an earthquake as to be comparatively safe."—MILNE *Earthquakes*, ch. 7, p. 126. (A., 1899.)

841. DISCOVERER OF BACTERIA—*Plain Business Man Makes His Own Lenses—Advances Microscopy.*—The first scientist who demonstrated the existence of micro-organisms was Anton van Leeuwenhoek. He was born at Delft, in Holland, in 1632, and enthusiastically pursued microscopy with primitive instruments. He corroborated Harvey's discovery of the circulation of the blood in the web of a frog's foot; he defined the red blood-corpuscles of vertebrates, the fibers of the lens of the human eye, the scales of the skin, and the structure of hair. He was neither educated nor trained in science, but in the leisure time of his occupation as a linen-draper he learned the art of grinding lenses, in which he became so proficient that he was able to construct a microscope of greater power than

had been previously manufactured. The compound microscope dates from 1590, and when Leeuwenhoek was about forty years old Holland had already given to the world both microscope and telescope.—NEWMAN *Bacteria*, ch. 1, p. 1. (G. P. P., 1899.)

842. DISCOVERY A GROWTH—*Many Contribute Items—One Mind Focuses All.*—It must not be supposed that to Pasteur is due the whole credit of the knowledge acquired respecting the cause of fermentation. He did not first discover these living organisms; he did not first study them and describe them; he was not even the first to suggest that they were the cause of the processes of fermentation or disease. But, nevertheless, it was Pasteur who "first placed the subject upon a firm foundation by proving with rigid experiment some of the suggestions made by others." Thus it has ever been in the times of new learning and discovery: many contributors have added their quota to the mass of knowledge, even tho one man appearing at the right moment has drawn the conclusions and proved the theory to be fact.—NEWMAN *Bacteria*, ch. 4, p. 113. (G. P. P., 1899.)

843. ——— ——— *Partial Views and Isolated Facts Combined in Grand Total.*—Whatever the uncertainty of the field, it is due to these pioneer minds to treat their labor with respect. What they see in the unexplored land in which they travel belongs to the world. By just such methods, and by just such men, the map of the world of thought is filled in—here from the tracing up of some great river, there from a bearing taken roughly in a darkened sky, yonder from a sudden glint of the sun on a far-off mountain peak, or by a swift induction of an adventurous mind from a momentary glimpse of a natural law. So knowledge grows; and in a century which has added to the sum of human learning more than all the centuries that are past it is not to be conceived that some further revelation should not await us on the highest themes of all.—DRUMMOND *Ascent of Man*, int.. p. 2. (J. P., 1900.)

844. ——— ——— *The Sciences Help One Another.*—Nothing which succeeds is entirely new. The new-born is unformed and incapable. The greatest things are born from a state of germ, so to say, and increase unperceived. Ideas fertilize each other. The sciences help each other; progress marches. Men often feel a truth, sympathize with an opinion, touch a discovery, without knowing it. The day arrives when a synthetic mind feels in some way an idea, almost ripe, becoming incarnate in his brain: he becomes enamored of it, he fondles it, he contemplates it. It grows as he regards it. He sees, grouping round it, a multitude of elements which help to support it. To him the idea becomes a doctrine. Then, like the apostles of Good Tidings, he becomes an evangelist, announces the truth, proves it by his works, and all recognize in him the author of the new contemplation of Nature, altho all know perfectly well that he has not invented the idea, and that many others before him have foreseen its grandeur.—FLAMMARION *Popular Astronomy*, bk. iv, ch. 1, p. 342. (A.)

845. DISCOVERY BEFORE HISTORY—*Origin of Fire.*—The life of the human race may be divided into two great periods, the prehistoric and historic. But human beings had done great things before they learned to write about their doings. Among other things, they had discovered the use of fire, both as a means of warming their bodies and cooking their food. Nobody can tell how or when fire was first introduced. Lucretius has a story which ascribes its origin to the rubbing together of dry tree-branches; but this is not a likely source of ignition. Forests are sometimes set ablaze by lightning, and this is a possible origin of our domestic fires. Again, savages have everywhere employed stone implements, shaping pieces of flint with sharp edges for knives, and with sharp points for arrow-heads and spears. Sparks were certainly thus produced, and such sparks may have been the ancestors of our fires.—TYNDALL *Heat a Mode of Motion*, lect. 1, p. 11. (A., 1900.)

846. DISCOVERY BY PLAIN PEOPLE—*Accident and Wit Combined.*—In the fall of 1745, the German artisans, and especially those of Leipsic, probably recognized that the electric machine had come into good market demand. So simple was the apparatus, and so astonishing its effects, that people who made no pretense to being scientific bought it out of curiosity, and amused themselves by repeating at home the experiments which the philosophers publicly exhibited in the lecture-rooms and laboratories. When a device is thus taken to the popular bosom, so to speak, the prediction may safely be hazarded that before long some one in an unexpected quarter will discover or invent something concerning it which the philosophers have never thought of or completely missed. And the more complex the intellectual gymnastics of a certain class of these erudite persons around it, the more certain it seems to be that the discoverer will be found to have solved the problem either by his simple wits or by accident and his wits combined.—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 15, p. 511. (J. W., 1898.)

847. DISCOVERY BY SPECTRUM ANALYSIS—*Rubidium and Cæsium Found—Thallium Added.*—When Bunsen and Kirchhoff, the celebrated founders of spectrum analysis, after having established by an exhaustive examination the spectra of all known substances, discovered a spectrum containing bands different from any known bands, they immediately inferred the existence of a new metal. They were operating

at the time upon a residue, obtained by evaporating one of the mineral waters of Germany. In that water they knew the unknown metal was concealed, but vast quantities of it had to be evaporated before a residue could be obtained sufficiently large to enable ordinary chemistry to grapple with the metal. They, however, hunted it down, and it now stands among chemical substances as the metal rubidium. They subsequently discovered a second metal which they called cæsium. Thus, having first placed spectrum analysis on a sure foundation, they demonstrated its capacity as an agent of discovery. Soon afterwards Mr. Crookes, pursuing the same method, discovered the bright green band of thallium, and obtained the salts of the metal which yielded it. The metal itself was first isolated in ingots by M. Lamy, a French chemist.—TYNDALL *Lectures on Light*, lect. 6, p. 195. (A., 1898.)

848. DISCOVERY CONFIRMS CONJECTURE—*The Antarctic Continent.*—The cold of the antarctic regions was conjectured by Cook to be due to the existence of a large tract of land between the seventieth degree of south latitude and the pole. The justness of these and other speculations of that great navigator have since been singularly confirmed by the investigation made by Sir James Ross in 1841. He found Victoria Land, extending from 71° to 79° S. latitude, skirted by a great barrier of ice, the height of the land ranging from 4,000 to 14,000 feet, the whole entirely covered with snow, except a narrow ring of black earth surrounding the huge crater of the active volcano of Mount Erebus, rising 12,400 feet above the level of the sea. The position of a mountainous territory of such altitude, so near the pole, and so obvious a source of intense cold, fully explains why Graham's and Enderby's Land, discovered by Captain Biscoe in 1831-2 (between lat. 64° and 68° S.), presented a most wintry aspect, covered even in summer with ice and snow, and nearly destitute of animal life. In corresponding latitudes of the northern hemisphere we not only meet with herds of wild herbivorous animals, but with land which man himself inhabits, and where he has even built ports and inland villages.—LYELL *Principles of Geology*, bk. i, ch. 7, p. 99. (A., 1854.)

849. DISCOVERY, LONG DELAY TO REALIZE—*Humanity Waiting.*—It is interesting, and indeed pathetic, to observe how long a discovery of priceless value to humanity may be hidden away, or rather lie openly revealed, before the final and apparently obvious step is taken towards its practical application. In 1837, Schwann clearly established the connection between putrefaction and microscopic life; but thirty years had to elapse before Lister extended to wounds the researches of Schwann on dead flesh and animal infusions.—TYNDALL *Floating Matter of the Air*, int., p. 9. (A., 1895.)

850. DISCOVERY MISSED—*Stopping with an Instance—Failure of Generalization.*—Again, at Paris, in 1849, with a view to testing the asserted coincidence between the solar D-line and the bright yellow beam in the spectrum of the electric arc (really due to the unsuspected presence of sodium), Léon Foucault threw a ray of sunshine across the arc and observed its spectrum. He was surprised to see that the D-line was rendered more intensely dark by the combination of lights. To assure himself still further, he substituted a reflected image of one of the white-hot carbon-points for the sunbeam, with an identical result. The same ray was missing. It needed but another step to have generalized this result, and thus laid hold of a natural truth of the highest importance; but that step was not taken. Foucault, keen and brilliant tho he was, rested satisfied with the information that the voltaic arc had the power of stopping the kind of light emitted by it; he asked no further question, and was consequently the bearer of no further intelligence on the subject.—CLERKE *History of Astronomy*, pt. ii, ch. 1, p. 170. (Bl., 1893.)

851. DISCOVERY OF AMERICA NOT AN ISOLATED EVENT—*Way Prepared by Science.*—The discovery of the tropical regions of America by Christopher Columbus . . . cannot be regarded in the history of the contemplation of the universe as one isolated event. . . . That which imparted to the age of Columbus its peculiar character of uninterrupted and successful efforts toward the attainment of new discoveries and extended geographical knowledge was prepared slowly and in various ways. The means which contributed most strongly to favor these efforts were a small number of enterprising men, who early excited a simultaneous and general freedom of thought, and an independence of investigation into the separate phenomena of Nature; the influence exercised on the deepest sources of mental vigor by the renewed acquaintance formed in Italy with the works of ancient Greek literature; the discovery of an art which lent to thought at once wings of speed and powers of perpetuity; and the more extended knowledge of eastern Asia acquired by traveling merchants, and by monks who had been sent on embassies to the Mogul rulers, and which was diffused by them among those nations of the southwest of Europe who maintained extensive commercial relations with other countries, and who were therefore most anxious to discover a nearer route to the Spice Islands. To these means . . . we must add the advance in the art of navigation, the gradual perfection of nautical instruments, both magnetic and astronomical, and, finally, the application of certain methods for the determination of the ship's place.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 240. (H., 1897.)

852. DISCOVERY OF AN ANCIENT BEACH—*Rock Marked by Waves of Vanished Sea.*—The gunpowder had loosened a large mass in one of the inferior strata, and our first employment, on resuming our labors, was to raise it from its bed. I assisted the other workmen in placing it on edge, and was much struck by the appearance of the platform on which it had rested. The entire surface was ridged and furrowed like a bank of sand that had been left by the tide an hour before. I could trace every bend and curvature, every cross-hollow and counter-ridge of the corresponding phenomena; for the resemblance was no half resemblance—it was the thing itself; and I had observed it a hundred and a hundred times, when sailing my little schooner in the shallows left by the ebb. But what had become of the waves that had thus fretted the solid rock, or of what element had they been composed? I felt as completely at fault as Robinson Crusoe did on his discovering the print of the man's foot on the sand.—MILLER *The Old Red Sandstone*, ch. 1, p. 7. (G. & L., 1851.)

853. DISCOVERY OF GRAVITATION—*Newton—Story of the Apple—Earth's Attraction Already Well Understood—Newton Saw the Same Law Pervading All Space.*—But it was not till Newton came that the true meaning of these laws [of Kepler] was ascertained, and very wonderful is the history of the process by which he solved the noble problem which Nature had presented to mankind for investigation. Every one has heard the story of the apple, whose fall is said to have suggested to Newton the great discovery for which his name will be deservedly celebrated for all time. The story may be true in a sense, tho not in the sense usually given to it. Newton certainly did not ask why the apple fell, since it was well understood in his day, and had been known for many centuries, that bodies fall to the earth by virtue of her attractive influence. But it is quite possible that Newton, who had long been engaged in profound meditation on the laws of planetary motion, should have suddenly seen revealed to him the possibility that a far wider law of attraction exists. His mind was full of the thoughts suggested by the mysterious energies which appear to sway the motions of the planets; and here, suddenly, his attention was called to the mysterious energy by which the earth draws bodies to her surface. What if one and the same form of force is exerted in all such cases? What if the sun draws the planets towards him, as the earth draws unsupported bodies towards her? What if the law exemplified in the fall of the apple is a universal law?—PROCTOR *Expanse of Heaven*, p. 110. (L. G. & Co.)

854. DISCOVERY OF MAMMOTH—*Remains Preserved in Icy Tomb.*—In 1799 a Tungusian hunter discovered the body of a mammoth embedded in a cliff of frozen soil, where it remained for several years. In 1806 it was visited by Mr. Adams, who found it partly devoured by wolves and other wild animals, and partly removed by the Yakuts, who used it as food for their dogs. Fortunately, however, a considerable portion of the animal still remained. The skin was dark gray, covered with reddish wool, mixed with long black bristles, somewhat thicker than horsehair. Another frozen mammoth was discovered in 1846, besides several other well-preserved portions, and it was probably from earlier finds of a similar nature that the Siberian tribes began to regard the mammoth as a gigantic burrowing animal. It is hardly necessary to observe that the state of preservation in which mammoths have been found is no evidence of recent existence, for when once enveloped in frozen soil they might remain unchanged for an indefinite period.—AVEBURY *Prehistoric Times*, ch. 9, p. 273. (A., 1900.)

855. DISCOVERY OF MEN THE CHIEF NEED—*Wealth Can Liberate Genius from Petty Toil and Care.*—Your most difficult problem [in the United States] will be not to build institutions, but to discover men. You may erect laboratories and endow them; you may furnish them with all the appliances needed for inquiry; in so doing you are but creating opportunity for the exercise of powers which come from sources entirely beyond your reach. You cannot create genius by bidding for it. In Biblical language, it is the gift of God; and the most you could do, were your wealth, and your willingness to apply it, a millionfold what they are, would be to make sure that this glorious plant shall have the freedom, light, and warmth necessary for its development. We see from time to time a noble tree dragged down by parasitic runners. These the gardener can remove, tho the vital force of the tree itself may lie beyond him: and so, in many a case, you men of wealth can liberate genius from the hampering toils which the struggle for existence often casts around it.—TYNDALL *Lectures on Light*, p. 227. (A., 1898.)

856. DISCOVERY OF THE GULF STREAM—*Franklin's Wide Inference from Partial Observation—Genius Coordinates Facts.*—It was Franklin who first systematically observed these facts, tho they had been noticed long before by navigators. He recorded the temperature of the water as he left the American continent for Europe, and found that it continued cold for a certain distance, then rose suddenly, and after a given time sank again to a lower temperature, tho not so low as before. With the comprehensive grasp of mind characteristic of all his scientific results, he went at once beyond his facts. He inferred that the warm current, keeping its way so steadily through the broad Atlantic, and carrying tropical productions to the northern shores of Europe, must take its rise in tropical regions, must

be heated by a tropical sun. This was his inference: to work it out, to ascertain the origin and course of the Gulf Stream, has been, in a great degree, the task of the United States Coast Survey, under the direction of his descendant, Dr. Bache.—AGASSIZ *Journey in Brazil*, ch. 1 p. 6. (H. M. & Co., 1896.)

857. DISCOVERY OF THE TRANSPARENCY OF AIR—*Smokelike Clouds of Darkness.*—In a cylindrical beam, which strongly illuminated the dust of the laboratory, I placed an ignited spirit-lamp. Mingling with the flame, and round its rim, were seen curious wreaths of darkness resembling an intensely black smoke. On placing the flame at some distance below the beam, the same dark masses stormed upwards. . . . What, then, was the blackness? It was simply that of stellar space; that is to say, blackness resulting from the absence from the track of the beam of all matter competent to scatter its light. When the flame was placed below the beam the floating matter was destroyed *in situ;* and the air, freed from this matter, rose into the beam, jostled aside the illuminated particles, and substituted for their light the darkness due to its own perfect transparency. Nothing could more forcibly illustrate the invisibility of the agent which renders all things visible. The beam crossed, unseen, the black chasm formed by the transparent air, while, at both sides of the gap, the thick-strewn particles shone out like a luminous solid under the powerful illumination.—TYNDALL *Floating Matter of the Air*, p. 3. (A., 1895.)

858. DISCOVERY, PHYSICAL—*Does Not Affect Spiritual Truth—Enduring Impressiveness of Scripture.*—No amount of knowledge of the kind which alone physical science can impart can do more than widen the foundation of intelligent spiritual beliefs. We think that astronomy and geology have given to us in these latter days ideas wholly new in respect to space and time. Yet, after all, can we express these ideas, or can we indicate the questions they suggest, in any language which approaches in power to the majestic utterances of David and of Job? We know more than they knew of the magnitude of the heavenly bodies; but what more can we say than they said of the wonder of them—of Orion, of Arcturus, and the Pleiades? [Job ix, 9.] We know that the earth moves, which they did not know; and we know that the rapid rotation of a globe on its own axis is a means of maintaining the steadiness of that axis in its course through space. But what effect, except that of increasing its significance, has this knowledge upon the praise which David ascribes to that ultimate agency which has made the round world so sure "that it cannot be moved"? [Ps. xciii. 1.]—ARGYLL *Reign of Law*, ch. 2, p. 68. (Burt.)

859. DISCOVERY, THE CHARM OF—*Compensation in Wonders of Science for Lack of New Lands to Explore.*—They err who believe that the conquistadores were incited by love of gold and religious fanaticism alone. Perils always exalt the poetry of life; and, moreover, the remarkable age, whose influence on the development of cosmical ideas we are now depicting, gave to all enterprises, and to the natural impressions awakened by distant travels, the charm of novelty and surprise, which is beginning to fail us in the present well-instructed age, when so many portions of the earth are opened to us. Not only one hemisphere, but almost two-thirds of the earth, were then a new and unexplored world, as unseen as that portion of the moon's surface which the law of gravitation constantly averts from the glance of the inhabitants of the earth. Our deeply inquiring age finds in the increasing abundance of ideas presented to the human mind a compensation for the surprise formerly induced by the novelty of grand, massive, and imposing natural phenomena—a compensation which will, it is true, long be denied to the many, but is vouchsafed to the few familiar with the condition of science. To them the increasing insight into the silent operation of natural forces, whether in electro magnetism or in the polarization of light, in the influence of diathermanous substances or in the physiological phenomena of vital organisms, gradually unveils a world of wonders, of which we have scarcely reached the threshold.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 271. (H., 1897.)

860. DISCOVERY VALUELESS WITHOUT SCIENTIFIC KNOWLEDGE—That this first discovery of America [by the Norsemen] in or before the eleventh century should not have produced the important and permanent results yielded to the physical contemplation of the universe by the rediscovery of the same continent by Columbus at the close of the fifteenth century was the necessary consequence of the uncivilized condition of the people, and the nature of the countries to which the early discoveries were limited. The Scandinavians were wholly unprepared, by previous scientific knowledge, for exploring the countries in which they settled, beyond what was absolutely necessary for the satisfaction of their immediate wants. Greenland and Iceland, which must be regarded as the actual mother countries of the new colonies, were regions in which man had to contend with all the hardships of an inhospitable climate.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 236. (H., 1897.)

861. DISCRIMINATION OF SCIENCE—*Surface Indications Not Decisive—The Shell-mounds of Denmark.*—The Museum of Northern Antiquities [of Copenhagen] contains an immense collection of specimens from some very interesting shell-mounds, which are known in Denmark under the

name of "Kjökkenmöddings" (derived from Kjökken, "kitchen," and mödding, corresponding to our local word midding, a "refuse heap") [in English commonly "kitchen-midden" or "-midding"], and were long supposed to be raised beaches, like those which are found at so many points along our own shores. True raised beaches, however, necessarily contain a variety of species; the individuals are of different ages, and the shells are, of course, mixed with a considerable quantity of sand and gravel. But it was observed, in the first instance, I believe, by Professor Steenstrup, that in these supposed beaches the shells belonged entirely to full-grown, or to nearly full-grown individuals; that they consisted of four species which do not live together, nor require the same conditions, and would not, therefore, be found together alone in a natural deposit; and, thirdly, that the stratum contained scarcely any gravel, but consisted almost entirely of shells.—AVEBURY *Prehistoric Times*, ch. 7, p. 214. (A., 1900.)

862. DISEASE DEALT WITH AS A FUNCTION OF A SOUL—*Auscultation and the Like All Needless.*—The vitalistic physician considered that the essential part of the vital processes did not depend upon natural forces, which, doing their work with blind necessity and according to a fixed law, determined the result. What these forces could do appeared quite subordinate, and scarcely worthy of a minute study. He thought that he had to deal with a soul-like being, to which a thinker, a philosopher, and an intelligent man must be opposed. . . . At this time auscultation and percussion of the organs of the chest were being regularly practised in the clinical wards. But I have often heard it maintained that they were a coarse mechanical means of investigation which a physician with a clear mental vision did not need; and it indeed lowered and debased the patient, who was anyhow a human being, by treating him as a machine.—HELMHOLTZ *Popular Lectures*, lect. 5, p. 218. (L. G. & Co., 1898.)

863. DISEASE ONCE MYSTERIOUS NOW EXPLAINED—*Tetanus or Lockjaw Caused by Bacteria.*—The pathology of this terrible disease [tetanus or lockjaw] has during recent years been considerably elucidated. It was the custom to look upon it as "spontaneous," and arising no one knew how; now, however, after the experiments of Sternberg and Nicolaier, the disease is known to be due to a micro-organism common in the soil of certain localities, existing there either as a bacillus or in a resting stage of spores. Fortunately tetanus is comparatively rare, and one of the peculiar biological characteristics of the bacillus is that it grows only in the absence of oxygen [whence the special danger of a punctured wound].—NEWMAN *Bacteria*, ch. 5, p. 168. (G. P. P., 1899.)

864. DISEASES, FUNCTIONAL, MAINTAINED BY HABIT—*Cure by Sudden Arrest.*—We find how many so-called functional diseases seem to keep themselves going simply because they happen to have once begun; and the forcible cutting short by medicine of a few attacks is often sufficient to enable the physiological forces to get possession of the field again, and to bring the organs back to functions of health. Epilepsies, neuralgias, convulsive affections of various sorts, insomnias, are so many cases in point. And, to take what are more obviously habits, the success with which a "weaning" treatment can often be applied to the victims of unhealthy indulgence of passion, or of mere complaining or irascible disposition, shows us how much the morbid manifestations themselves were due to the mere inertia of the nervous organs, when once launched on a false career.—JAMES *Psychology*, vol. i, ch. 4, p. 106. (H. H. & Co., 1899.)

865. DISINFECTION, PROBLEM OF—*In Many Cases to Kill Microbes without Killing Patient, or Destroying Property.*—It should at the outset be understood that we desire in practical disinfection to inhibit or kill micro-organisms without injury to or destruction of the substance harboring the germs for the time being. If this latter is of no moment, as in rags or carcasses, burning is the simplest and most thorough treatment. But with mattresses and beddings, bedclothes and garments, as well as with the human body, it is obvious that something short of burning is required.—NEWMAN *Bacteria*, ch. 9, p. 325. (G. P. P., 1899.)

866. DISINTEGRATION OF MOUNTAINS—*Falling Fragments of Matterhorn—A Sudden Avalanche of Rocks (Job xiv, 18).*—Again and again we looked to the cliffs [of the Matterhorn] above us, ignorant of the treatment that we were to receive at their hands. We had gathered up our traps, and bent to the work before us, when suddenly an explosion occurred overhead. We looked aloft and saw in mid-air a solid shot from the Matterhorn, describing its proper parabola, and finally splitting into fragments as it smote one of the rocky towers in front of us. Down the scattered fragments came like a kind of spray, slightly wide of us, but still near enough to compel a sharp lookout. Two or three such explosions occurred, but we chose the back-fin of the mountain for our track, and from this the falling stones were speedily deflected right or left. Before the set of sun we reached our place of bivouac.—TYNDALL *Hours of Exercise in the Alps*, ch. 14, p. 158. (A., 1898.)

867. DISINTEGRATION OF ROCKS—*Earth and Ocean-floor Covered with Rock-débris.*—The disintegration and decomposition of rocks is a process everywhere being

carried on—from the crests of the mountains down to the sea, and in every latitude under the sun. No exposed rock-surface escapes attack. In parched deserts as in well-watered regions, in the dreary barrens of the far north as in the sunny lands of the south, at lofty elevations as in low-lying plains, the work of rock-waste never ceases. Here it is insolation that is the most potent agent of destruction: there it is rain aided by humus and carbonic acids; or rain and frost combine their forces to shatter and pulverize the rocks. In latitudes where frost acts energetically, the most conspicuous proofs of rock-waste are the sheets and heaps of débris that are ever traveling down mountain slopes, or gathering at the base of cliff and precipice. In lower latitudes the most impressive evidence of disintegration is the great thickness attained by rotted rock in positions where it is not liable to be readily swept away by running water.—GEIKIE *Earth Sculpture*, ch. 2, p. 29. (G. P. P., 1898.)

868. ——— ——— *Heat and Cold Break Down—Wind Scatters in Dust.*—Rocks at the surface are everywhere subject to changes of temperature—warmed by day and during summer, cooled at night and during winter. Thus they alternately expand and contract, and this tends to disintegration, for the materials of which they are composed often yield unequally to strain or tension. In the rocky deserts of tropical and subtropical regions, bare of verdure and practically rainless, the effects produced by alternate heating and cooling are very marked. The rocks are cracked and shattered to a depth of several inches; the surfaces peel off, and are rapidly disintegrated and pulverized. Wind then catches up the loose material and sweeps it away, leaving fresh surfaces exposed to the destructive action of insolation. More than this, the grit, sand, and dust carried off by the wind are used as a sand-blast to attack and erode the rocks against which they strike.—GEIKIE *Earth Sculpture*, ch. 2, p. 23. (G. P. P., 1898.)

869. DISORDERS OF SOCIETY FROM TRANSGRESSION OF NATURAL LAW—*Evil Points the Way to Betterment.*—Is it vain to hope that the thoughtfulness and candor which have been the natural inheritance of a few may yet be more common among all educated men? The whole constitution and course of things would receive an earlier fulfilment did we carry about with us an habitual belief in the inexhaustible treasures which it holds—in the power of the agencies which it offers to knowledge and contrivance. For then the results of natural consequence would be accepted for that which they teach, and not simply submitted to for that which they inflict. The disorders of society would not so often be supinely regarded as the result of inevitable laws, but would be seen as the fruit always of some ignorance or of some rebellion; and so the exhilarating conviction would be ours that those disorders are within the reach of remedy through larger knowledge and a better will.—ARGYLL *Reign of Law*, ch. 7, p. 229. (Burt.)

870. DISPERSAL OF PLANTS—*Effected by Animals.*—Sometimes an express provision is found in the structure of seeds to enable them to adhere firmly by prickles, hooks, and hairs, to the coats of animals, or feathers of the winged tribe, to which they remain attached for weeks, or even months, and are borne along into every region whither birds or quadrupeds may migrate. Linnæus enumerates fifty genera of plants, and the number now known to botanists is much greater, which are armed with hooks, by which, when ripe, they adhere to the coats of animals. . . . A deer has strayed from the herd when browsing on some rich pasture, when he is suddenly alarmed by the approach of his foe. He instantly takes to flight, dashing through many a thicket, and swimming across many a river and lake. The seeds of the herbs and shrubs which have adhered to his smoking flanks are washed off again by the waters. The thorny spray is torn off, and fixes itself in its hairy coat, until brushed off again in other thickets and copses.—LYELL *Principles of Geology*, ch. 37, p. 624. (A., 1854.)

871. ——— ——— *Effected by Man.*—Besides the plants used in agriculture, the numbers which have been naturalized by accident, or which man has spread unintentionally, are considerable. One of our old authors, Josselyn, gives a catalog of such plants as had, in his time, sprung up in the colony since the English planted and kept cattle in New England. They were two-and-twenty in number. The common nettle was the first which the settlers noticed: and the plantain was called by the Indians "Englishman's foot," as if it sprung from their footsteps.—LYELL *Principles of Geology*, ch. 37, p. 625. (A., 1854.)

872. DISPERSAL OF SEEDS GRADUAL—*Nature's Thrashing-machine—Balls of Buttonwood.*—The fruit of the buttonwood, or sycamore, which grows along streams, is in the form of balls an inch and a half in diameter. These balls grow on the tops of the highest branches, and hold on into winter or longer. The stems are about two inches long, and soon after drying, through the action of the winds, they become very flexible, each resembling a cluster of tough strings. The slightest breeze moves them, and they bob around against each other and the small branches in an odd sort of way. After so much thrashing that they can hold no longer, the little nuts become loosened and begin to drop off a few at a time. Certain birds eat a few and loosen others, which escape, . . . each supplied with a ring of bristles about the base, which acts as a

parachute to permit the wind the easier to carry them for some distance before falling, or to drift them on the surface of the snow or ice.—BEAL *Seed Dispersal,* ch. 5, p. 39. (G. & Co., 1898.)

873. DISPUTATION ON NAMES RATHER THAN THINGS—*Agreement amid Controversy.*—A man that is of judgment and understanding shall sometimes hear ignorant men differ, and know well within himself that those which so differ mean one thing, and yet they themselves would never agree; and if it come so to pass in that distance of judgment which is between man and man, shall we not think that God above, that knows the heart, doth not discern that frail men, in some of their contradictions, intend the same thing; and accepteth of both?—BACON *Essays,* essay 4, *Of Revenge,* p. 15. (W. L. A.)

874. DISTANCE OF ONLY ONE STAR CERTAINLY KNOWN—Tho no discredit whatever can attach to astronomers for failing to determine exactly quantities which are in reality all but evanescent, yet no more reliance must be placed on the estimates of star-distances than shall appear to be justified by the accordance of different and independent determinations. . . . So that the startling but inevitable conclusion is deduced that there is but one star in the heavens of whose distance astronomers have any definite ideas. This star is the one known as Alpha Centauri; and hitherto all observations agree in placing it at about twenty-two millions of millions of miles from the earth.—PROCTOR *Our Place among Infinities,* p. 167. (L. G. & Co., 1897.)

875. DISTANCE OF SUN FROM EARTH—*Expressed in Speed of Cannon-ball and of Railroad Train.*—As to the distance of ninety-three million miles, a cannon-ball would travel it in about fifteen years. It may help us to remember that at the speed attained by the limited express on our railroads a train which had left the sun for the earth when the "Mayflower" sailed from Delftshaven with the Pilgrim Fathers, and which ran at that rate day and night, would in 1887 still be a journey of some years away from its terrestrial station. The fare at the customary rates, it may be remarked, would be rather over two million five hundred thousand dollars, so that it is clear that we should need both money and leisure for the journey.—LANGLEY *New Astronomy,* ch. 1, p. 5. (H. M. & Co., 1896.)

876. DISTANCE PENETRATED—*Spectroscope Measures Orbits and Speed of Stars by Light That Left Them Forty-seven Years Ago.*—[Dr. Vogel] from his study of the spectra of the variable star Algol, has been able to determine that both the visible star and its dark companion are somewhat larger than our sun, tho of less density; that their centers are 3,230,000 miles apart, and that they move in their orbits at rates of 55 and 26 miles per second respectively; and this information, it must be remembered, has been gained as to objects the light of which takes about forty-seven years to reach us!—WALLACE *The Wonderful Century,* ch. 6, p. 48. (D. M. & Co., 1899.)

877. DISTANCES, INCONCEIVABLE, OF THE STARS—*Light Millions of Years in Coming Thence—Exalted Ideas of Time and Space.*—Now, light takes more than eight minutes in reaching us from the sun, whose distance is more than 91,000,000 of miles; and it is easily calculated that the long journey from Sirius cannot be traversed in less than fifteen years. More probably it requires upwards of twenty years; and the greater number of the stars we see on a dark and clear night lie very much farther away than Sirius. Some of them certainly lie at distances which light can only traverse in hundreds of years. So soon as we turn, however, to telescopic stars, the range of time over which our vision extends is enormously increased, and it is certainly not too much to say that some of the fainter stars revealed by the great Rosse telescope lie at distances so enormous that their light has taken more than a hundred thousand years in reaching us. Then beyond these stars lie millions and millions of orbs yet farther away. There is no limit to the range of space occupied thus with the work of God's hands. All that has been taught us by astronomy suggests the lesson that every moment light reaches this earth from unseen orbs so far away that the journey over the vast abysses separating us from them has not been completed in less than millions of years.—PROCTOR *Expanse of Heaven,* p. 202. (L. G. & Co., 1897.)

878. ——— ——— *Yet Far-off Stars Obey Unchanging Law.*—But it was not merely in the region of the attraction of our sun that the law of gravitation was found to hold. With regard to the fixed stars, it was found that double stars moved about each other in elliptical paths, and that therefore the same law of gravitation must hold for them as for our planetary system. The distance of some of them could be calculated. The nearest of them, *α* in the constellation of the Centaur, is 270,000 times further from the sun than the earth. Light, which has a velocity of 186,000 miles a second, which traverses the distance from the sun to the earth in eight minutes, would take four years to travel from *α* Centauri to us. The more delicate methods of modern astronomy have made it possible to determine distances which light would take thirty-five years to traverse—as, for instance, the pole-star; but the law of gravitation is seen to hold, ruling the motion of the double stars, at distances in the heavens, which all the means we possess have hitherto utterly failed to measure.—HELMHOLTZ *Popular Lectures,* lect. 4, p. 149. (L. G. & Co., 1898.)

879. DISTINCTION BETWEEN SUCCESSION AND CAUSATION—*Day and Night vs. Rotation of the Earth.*—He [Comte] has an objection to the word cause; he will only consent to speak of laws of succession: and depriving himself of the use of a word which has a positive meaning, he misses the meaning it expresses. He sees no difference between such generalizations as Kepler's laws and such as the theory of gravitation. He fails to perceive the real distinction between the laws of succession and coexistence which thinkers of a different school call laws of phenomena, and those of what they call the action of causes: the former exemplified by the succession of day and night, the latter by the earth's rotation which causes it. The succession of day and night is as much an invariable sequence as the alternate exposure of opposite sides of the earth to the sun. Yet day and night are not the causes of one another; why? Because their sequence, tho invariable in our experience, is not unconditionally so: those facts only succeed each other, provided that the presence and absence of the sun succeed each other; and if this alternation were to cease, we might have either day or night unfollowed by one another. There are thus two kinds of uniformities of succession, the one unconditional, the other conditional on the first: laws of causation, and other successions dependent on those laws.—MILL *Positive Philosophy of Auguste Comte*, p. 54. (H. H. & Co., 1887.)

880. DISTINCTIONS LITTLE NOTED BY AVERAGE MIND—*Horse-stealing vs. Sheep-stealing.* — Professor de Morgan, thinking, it is true, rather of conceptual than of perceptive discrimination, wrote, wittily enough:

"The great bulk of the illogical part of the educated community—whether majority or minority I know not: perhaps six of one and half a dozen of the other—have not power to make a distinction, and of course cannot be made to take a distinction, and of course never attempt to shake a distinction. With them all such things are evasions, subterfuges, come-offs, loopholes, etc. They would hang a man for horse-stealing under a statute against sheep-stealing, and would laugh at you if you quibbled about the distinction between a horse and a sheep."—JAMES *Psychology*, vol. i, ch. 12, p. 509. (H. H. & Co., 1899.)

881. DISTRACTION OF ATTENTION FROM GRIEF—*Help to Forgetfulness—Volition the Latest Resource.*—We will take the case of a man who has sustained a great shock by the loss of a dearly loved wife, child, or friend, a disappointed affection, or commercial ruin. His physical condition is lowered, the power of his will is weakened, the painful impression seems branded into his innermost nature, he cannot help feeling it most acutely, he seems powerless to withdraw himself from it. He may be exhorted to "rouse himself"; every conceivable motive may be suggested to him for doing so; but all in vain. What is needed is the complete distraction of his attention from brooding over his misfortune; and the force which the weakened will cannot of itself exert must be supplied by the attractive influence of new scenes and persons, and the complete severance from painful associations. He yields himself passively to his advisers; at first "all seems barren, from Dan to Beersheba"; he looks up into the dome of St. Peter's, or down into the crater of Vesuvius, and finds "nothing in it." But gradually his bodily health improves; he begins to show some interest in what he sees and hears; and a judicious companion, like a good nurse, watches for every sign, and encourages every movement in the right direction, noticing what proves most attractive, and secretly planning to bring its attractions into play. At first the patient seems ashamed of being cheerful, and falls back into his moodiness, as if he felt it a duty to hug the memory of his lost happiness; but these relapses, after a time, become less and less frequent. He begins to find that it is really much pleasanter to forget himself, and to make himself agreeable to others, than it is to brood morosely over his troubles. With the reinvigoration of his bodily health, his volitional power gradually returns; and he comes to feel that he can resist the tendency to revert to them by determinately giving his attention to the objects around him. The resisting power required becomes less and less the more frequently it is exerted, and at length the mental health is completely restored—the brooding tendency, however, being apt to recur, either when the will is weakened by physical fatigue, or when old associations are revived with peculiar force and vividness.—CARPENTER *Mental Physiology*, bk. i, ch. 7, p. 334. (A., 1900.)

882. DISTRIBUTION, GRADUAL, OF MAMMALIA OVER THE EARTH—It is evident that the distribution of animals over the earth's surface to-day, or their distribution through past time, as evidenced by their fossil remains, both point to a gradual and natural origin and distribution of every kind of beast composing the mammalian class. We say of every kind of beast, because as regards man no reasonable opinion could be gathered from the facts set down in this series of essays.—MIVART *Types of Animal Life*, ch. 12, p. 374. (L. B. & Co., 1893.)

883. DISTRIBUTION OF PLANTS STRIKINGLY IRREGULAR—The struggle for existence in plants is, therefore, threefold in character and infinite in complexity, and the result is seen in their curiously irregular distribution over the face of the earth. Not only has each country its distinct plants, but every valley, every hillside, almost every hedgerow, has a different

set of plants from its adjacent valley, hill-side, or hedgerow—if not always different in the actual species, yet very different in comparative abundance, some which are rare in the one being common in the other.—WALLACE *Darwinism*, ch. 2, p. 12. (Hum., 1889.)

884. DISTRIBUTION OF SEEDS—*The Milkweed.*—Every one who has wandered along a country road has noticed the peculiar seed-pods of the common milkweed. . . . As the pods open there is revealed a large number of flattened brown seeds. . . . Each seed bears on its smaller end a tuft of silken hairs. When the pod first opens these hairs lie straight and flat, the ends of the hairs being caught in the folds of the membranous partition which runs through the center of the pod.

On exposure to the air the folds relax their hold upon the hairs, which thus become free at their upper ends. Then each hair curls over toward the other end of the seed, until at last nearly all the hairs on the upper seeds are thus curled over, forming a beautiful crown almost as light as air. When a strong wind blows, the seeds are picked up by means of these hairs and carried away to be dropped beside some fence or tree or bush. By the beautiful device of this feathery crown the milkweed provides for the scattering of its seeds. It seems a simple process, but as you think it over you see that it is a very admirable one.—WEED *Seed-travellers*, pt. i, p. 1. (G. & Co., 1899.)

885. DISTRIBUTION OF STARS UNEQUAL—*Rich and Poor Celestial Regions—Magellanic Clouds—Aggregations of Light and Power.*—In working, then, by the method of charting I began (for I may as well note that I have been practically alone in this work) by charting the stars that we can see, according to a plan by which the laws of distribution should be clearly recognized; for the charts I drew were so contrived that equal spaces on the celestial sphere should be represented by equal spaces in the chart. It quickly became clear that the stars are not scattered at all uniformly over the heavens. There are rich and poor regions; and these are so arranged that while the whole of the galactic region is exceedingly rich in naked-eye stars, two opposite rich regions, one in the northern and the other in the southern heavens, are separated from each other (except where the Milky Way on opposite sides passes from one to the other) by singularly barren regions. It appears a noteworthy circumstance that near the center of the great southern rich region are found those two wonderful objects called the Magellanic clouds, vast globe-shaped conglomerations (scarcely any other word seems so suitable) in which are contained not only myriads of stars of all orders of magnitude after the seventh, but also every kind of star cloudlet.—PROCTOR *Expanse of Heaven*, p. 268. (L. G. & Co., 1897.)

886. DIVING-BELL, THE FIRST—*Home of the Water-spider—Transporting and Storing Air.*—The water-spider (*Argyroneta aquatica*), as is well known, displays the curious instinct of building her nest below the surface of water, and constructing it on the principle of a diving-bell. The animal usually selects still waters for this purpose, and makes her nest in the form of an oval hollow, lined with web, and held secure by a number of threads passing in various directions and fastened to the surrounding plants. In this oval bell, which is open below, she watches for prey, and, according to Kirby, passes the winter after having closed the opening. The air needful for respiration the spider carries from the surface of the water. To do this she swims upon her back in order to entangle an air-bubble upon the hairy surface of her abdomen. With this bubble she descends, "like a globe of quicksilver," to the opening of her nest, where she liberates it and returns for more.—ROMANES *Animal Intelligence*, ch. 6, p. 211. (A., 1899.)

887. DIVISION BY DEPRESSION AMONG THE FAUNA OF THE DEEP SEA—It would be quite possible, however, to subdivide the [terrestrial] geographical areas into zones of elevation above the sea-level, not very clearly marked off from one another, it is true, but nevertheless each showing a number of characteristic features. This idea is expressed, for example, when we speak of the Alpine fauna, the Himalayan fauna, or the fauna of the great Andes.

In the study of the marine fauna and flora we must notice, it is the depth of the water, or in other words the depression of the habitats below the sea-level, that forms the most important consideration. Geographical subregions may be recognized and defined with a certain amount of accuracy, especially in the case of the fauna of the shallow waters, but by far the most important changes in the general characters of the fauna are found when we pass from one "zone" of depression to another.—HICKSON *Fauna of the Deep Sea*, ch. 3, p. 46. (A., 1894.)

888. DIVISION LESSENS CONDUCTIVITY—*Red-hot Iron Ball Held in the Hand—Cause of Warmth of Fur.*—Pure silica, in the state of hard rock-crystal, is a better conductor than bismuth or lead; but if the crystal be reduced to powder, the propagation of heat is exceedingly slow. Through transparent rock salt heat is copiously conducted, through common table salt very feebly. Asbestos is composed of certain silicates in a fibrous condition; I place some asbestos on my hand, and on it a red-hot iron ball. The ball can be thus held without inconvenience. That the division of the substance should interfere with the transmission might reasonably be inferred: for, heat being motion, anything which disturbs the continuity of the molecular chain, along which the motion is conveyed, must affect

the transmission. In the case of the asbestos, the fibers are separated from each other by spaces of air; the motion has to pass from solid to air, and from air to solid. It is easy to see that the transmission of vibratory motion through this composite texture must be very imperfect. In the case of an animal's fur this is more especially the case; for here, not only do spaces of air intervene between the hairs, but the hairs themselves, unlike the fibers of the asbestos, are very bad conductors. Lava has been known to flow over a layer of ashes underneath which was a bed of ice, the non-conductivity of the ashes saving the ice from fusion. Red-hot cannon-balls have been wheeled to the gun's mouth in wooden barrows partially filled with sand. Ice is packed in sawdust, to prevent it from melting; powdered charcoal is also an eminently bad conductor.—TYNDALL *Heat a Mode of Motion*, lect. 9, p. 258. (A., 1900.)

889. DIVISION OF BIELA'S COMET —*An Unexpected Astronomical Spectacle.*—It [Biela's comet] was seen again in 1845, on November 25, near the place assigned to it by calculation, and its course was duly followed. Everything went on to the general satisfaction, when—unexpected spectacle!—on January 13, 1846, the comet split into two! What had passed in its bosom? Why this separation? What was the cause of such a celestial cataclysm? We do not know; but the fact is that, instead of one comet, two were henceforth seen, which continued to move in space like two twin sisters—two veritable comets, each having its nucleus, its head, its coma, and its tail, slowly separating from each other; on February 10 there was already 60,000 leagues (about 149,000 miles) of space between the two. They would seem, however, to have parted with regret, and during several days a sort of bridge was seen thrown from one to the other. The cometary couple, departing from the earth, soon disappeared in the infinite night.

They returned within view of the earth in the month of September, 1852; on the 26th of this month the twins reappeared, but much farther apart, separated by an interval of 500,000 leagues (about 1,250,000 miles).—FLAMMARION *Popular Astronomy*, bk. v, ch. 2, p. 499. (A.)

890. DIVISION OF LABOR—*Among Ancient Organisms—Distinctive Organs Mark Higher Type of Structure.*—Other species of bivalves were also introduced, approaching more nearly our clams and oysters. . . . They differ from the brachiopods chiefly in the higher character of their breathing apparatus; for they have free gills, instead of the network of vessels on the lining skin which serves as the organ of respiration in the brachiopods. We shall always find that in proportion as the functions are distinct, and, as it were, individualized by having special organs appropriated to them, animals rise in the scale of structure.—AGASSIZ *Geological Sketches*, ser. i, ch. 3, p. 85. (H. M. & Co., 1896.)

891. ——— ——— *Between Associated Organisms—Lichens Communities of Algæ and Fungi—Organisms Mutually Cooperating.* — Incredible as the statement once seemed, it is a statement now accepted, that what we know as lichens, and used to consider as plants forming a certain low class, are now found to be not plants in the ordinary sense at all, but compound growths formed of minute algæ and minute fungi, carrying on their lives together: the algæ furnishing to the fungi certain constituents they need, but cannot directly obtain, and the fungi profiting by certain materials they obtain from the algæ, either while living or while individually decaying. Whence it would seem that after the microscopic vegetal type had become in a large degree differentiated into two main types, in adaptation to different conditions of life, and had acquired appropriate specialties of nature, there grew up this communistic arrangement between certain of them, enabling each to benefit by the powers which the other had acquired: evidently an exchange of services, a physiological division of labor, a mutual dependence of functions analogous to that which exists between functions in an ordinary plant or animal.—SPENCER *Biology*, pt. v, ch. 10A, p. 339. (A., 1900.)

892. ——— ——— *Marks the Progress of Nations.*—A comparative survey of the history of nations, or what is called "universal history," will readily yield to us, as the first and most general result, evidence of a continually increasing variety of human activities, both in the life of individuals and in that of families and states. This differentiation or separation, this constantly increasing divergence of human character and the form of human life, is caused by the ever advancing and more complete division of labor among individuals. While the most ancient and lowest stages of human civilization show us throughout the same rude and simple conditions, we see in every succeeding period of history, among different nations, a greater variety of customs, practises, and institutions.—HAECKEL *History of Creation*, vol. i, ch. 12, p. 319. (K. P. & Co., 1899.)

893. DIVISION OF PERSONALITY BY PHRENOLOGY—*Horse Inside of Locomotive.*—"We have [according to phrenology] a parliament of little men together, each one of whom, as happens also in a real parliament, possesses but a single idea which he ceaselessly strives to make prevail"—benevolence, firmness, hope, and the rest. "Instead of one soul, phrenology gives us forty, each alone as enigmatic as the full aggregate psychic life can be. Instead of dividing the latter into effective elements, she divides it into personal beings of peculiar character. . . . 'Herr Pastor, sure there

be a horse inside,' called out the peasants to X after their spiritual shepherd had spent hours in explaining to them the construction of the locomotive. With a horse inside truly everything becomes clear, even tho it be a queer enough sort of horse—the horse itself calls for no explanation! Phrenology takes a start to get beyond the point of view of the ghostlike soul entity, but she ends by populating the whole skull with ghosts of the same order." [Quoted from Lange, "Geschichte des Materialismus," 2d ed., vol. ii, p. 345.]—JAMES *Psychology*, vol. i, ch. 2, p. 29. (H. H. & Co., 1899.)

894. DOGMA DANGEROUS TO DISPUTE—*Air in Arteries of the Dead—Therefore of the Living—The Liver a Manufactory of Blood.*—The fact that air is generally found in the arteries of dead bodies, which indeed only penetrates in the moment in which the vessels are cut, led the ancients to the belief that air is also present in the arteries during life. The veins only remained then in which blood could circulate. It was believed to be formed in the liver, to move from there to the heart, and through the veins to the organs. Any careful observation of the operation of blood-letting must have taught that, in the veins, it comes from the periphery, and flows towards the heart. But this false theory had become so mixed up with the explanation of fever and of inflammation that it acquired the authority of a dogma, which it was dangerous to attack.—HELMHOLTZ *Popular Lectures*, lect. 5, p. 211. (L. G. & Co., 1898.)

895. DOGMAS ONCE IDENTIFIED WITH RELIGION—*Christianity Not Shaken by Their Overthrow.*—We of the present time can only wonder at the obstinacy with which the self-styled "orthodox" have clung to the idea that the world with its living inhabitants was created in six successive days of the year 4004 B. C., the Creator resting from his labors on the seventh; that our own terrestrial globe is the fixed center of the universe—sun and moon, stars and planets, revolving around it every twenty-four hours; that not more than 6,000 years have elapsed since man was first called into being; and that the Noachian deluge extended over the whole globe and destroyed all the animals then living on its surface, except the few pairs that found a refuge in the ark. As each of these positions has been successively impugned by scientific research, theologians have raised the cry that the foundations of Christianity were being undermined; and yet they have now, tacitly if not openly, agreed to abandon them all, as ancient traditions altogether destitute of historical value. That theology has gained and not lost by this abandonment, I do not suppose that any one now doubts.—CARPENTER *Nature and Man*, lect. 15, p. 410. (A., 1889.)

896. DOGMATISM OF SCIENTIST—*Experience to Prove Matter Eternal.*—Creation in the former sense, as the coming into existence of matter, does not concern us here at all. This process, if indeed it ever took place, is completely beyond human comprehension, and can therefore never become a subject of scientific inquiry. Natural science teaches that matter is eternal and imperishable, for experience has never shown us that even the smallest particle of matter has come into existence or passed away.—HAECKEL *History of Creation*, vol. i, ch. 1, p. 8. (K. P. & Co., 1899.)

897. DOGS INSEPARABLE AND UNIVERSAL COMPANIONS OF MEN—Since the discovery of flint tools in the superficial formations of many parts of the world, all geologists believe that barbarian men existed at an enormously remote period; and we know that at the present day there is hardly a tribe so barbarous as not to have domesticated at least the dog.—DARWIN *Origin of Species*, ch. 1, p. 16. (Burt.)

898. DOGS MADE OBJECTS OF WORSHIP—*Wild Dogs of European Extraction—Native Dogs of South America.*—In the pampas of Buenos Ayres the traveler meets with European dogs, which have become wild. They live gregariously in holes and excavations, in which they conceal their young. When the horde becomes too numerous, several families go forth, and form new settlements elsewhere. The European dog barks as loudly after it has become wild as does the indigenous American hairy species. Garcilaso asserts that, prior to the arrival of the Spaniards, the Peruvians had a race of dogs called *Perros gozques;* and he calls the indigenous dog *Allco.* In order to distinguish this animal from the European variety, it is called in the Qquichua language *Runa-allco*, Indian dog, or dog of the natives. The hairy *Runa-allco* appears to be a mere variety of the shepherd's dog. It is, however, smaller, has long yellow-ochery colored hair, is marked with white and brown spots, and has erect and pointed ears. It barks continually, but seldom bites the natives, however it may attack the whites. When the Inca Pachacutec, in his religious wars, conquered the Indians of Xauxa and Huanca (the present valley of Huancaya and Jauja), and compelled them by force to submit to the worship of the sun, he found that dogs were made the objects of their adoration, and that the priests used the skulls of these animals as wind-instruments. It would also appear that the flesh of this canine divinity was eaten by the believers.—HUMBOLDT *Views of Nature*, p. 85. (Bell, 1896.)

899. DOING, VALUE OF—*Contrast with Mere Saying—Determines Character (Matt. vii, 24-29).*—The most colossal improvement which recent years have seen in secondary education lies in the introduction of the manual training-schools; not because they will give us a people more handy and

practical for domestic life and better skilled in trades, but because they will give us citizens with an entirely different intellectual fiber. Laboratory work and shop work engender a habit of observation, a knowledge of the difference between accuracy and vagueness, and an insight into Nature's complexity and into the inadequacy of all abstract verbal accounts of real phenomena, which, once wrought into the mind, remain there as lifelong possessions. They confer precision; because, if you are doing a thing, you must do it definitely right or definitely wrong. They give honesty; for, when you express yourself by making things, and not by using words, it becomes impossible to dissimulate your vagueness or ignorance by ambiguity. They beget a habit of self-reliance; they keep the interest and attention always cheerfully engaged, and reduce the teacher's disciplinary functions to a minimum.—JAMES *Talks to Teachers*, ch. 5, p. 35. (H. H. & Co., 1900.)

900. DOMESTICATION OF ANIMALS—*Wonderful Triumph of Humanity.*—Nowhere has man pressed his hand so effectively upon Nature as in the domestication of animals. It is almost incredible that ravening wolves and merciless felines should become faithful dogs and purring cats; that the wild sheep and goat should descend from their inaccessible fastnesses, and yield their fleece and flesh and milk; that horses, asses, camels, elephants, should be induced to lend their backs and limbs to lighten the loads of the first common carrier. This process of impressing his own qualities on wild creatures began very early in history and has continued uninterruptedly from first to last. —MASON *The Birth of Invention. Address at Centenary of Amer. Patent System, Washington, D. C., 1891, Proceedings of the Congress*, p. 410

901. DOMESTICITY — *Woman Makes Home—A Child Its Center.*—With the physical program carried out to the last detail, the ethical drama opened. An early result, partly of her sex, and partly of her passive strain, is the founding through the instrumentality of the first savage mother of a new and a beautiful social state—domesticity. While man, restless, eager, hungry, is a wanderer on the earth, woman makes a home. And tho this home be but a platform of sticks and leaves, such as the gorilla builds on a tree, it becomes the first great schoolroom of the human race. For one day there appears in this roofless room that which is to teach the teachers of the world —a little child.—DRUMMOND *Ascent of Man*, ch. 8, p. 280. (J. P., 1900.)

902. DOMINION OF MAN OVER NATURE—*Power of Coordinating Impressions—Analysis and Comparison of Ideas the Foundation of Human Language.*—Beyond a doubt, man . . . in some way possesses, by virtue of his superior brain, a power of coordinating the impressions of his senses, which enables him to understand the world he lives in, and by understanding to use, resist, and even in a measure rule it. No human art shows the nature of this human attribute more clearly than does language. Man shares with the mammalia and birds the direct expression of the feelings by emotional tones and interjectional cries; the parrot's power of articulate utterance almost equals his own; and, by association of ideas in some measure, some of the lower animals have even learned to recognize words he utters. But, to use words in themselves unmeaning, as symbols by which to conduct and convey the complex intellectual processes in which mental conceptions are suggested, compared, combined, and even analyzed, and new ones created—this is a faculty which is scarcely to be traced in any lower animal.—DANIEL WILSON *Anthropology*, ch. 2, p. 5. (Hum., 1885.)

903. ——— ——— *Control by Obedience to Law.*—A great philosopher has observed that we can command Nature only by obeying her laws; and this principle is true even in regard to the astonishing changes which are superinduced in the qualities of certain animals and plants by domestication and garden culture. . . . We can only effect such surprising alterations by assisting the development of certain instincts, or by availing ourselves of that mysterious law of their organization by which individual peculiarities are transmissible from one generation to another.—LYELL *Principles of Geology*, bk. i. ch. 9, p. 151. (A., 1854.)

904. DOUBT AS A DISEASE—*Skepticism Carried to Absurdity—Discussion Preventing Action.*—"To one whose mind is healthy thoughts come and go unnoticed; with me they have to be faced, thought about in a peculiar fashion, and then disposed of as finished, and this often when I am utterly wearied and would be at peace; but the call is imperative. This goes on to the hindrance of all natural action. If I were told that the staircase was on fire and I had only a minute to escape, and the thought arose—'Have they sent for fire-engines? Is it probable that the man who has the key is on hand? Is the man a careful sort of person? Will the key be hanging on a peg? Am I thinking rightly? Perhaps they don't lock the depot'—my foot would be lifted to go down; I should be conscious to excitement that I was losing my chance; but I should be unable to stir until all these absurdities were entertained and disposed of. In the most critical moments of my life, when I ought to have been so engrossed as to leave no room for any secondary thoughts, I have been oppressed by the inability to be at peace. And in the most ordinary circumstances it is all the same. Let me instance the other morning I went to walk. The day was biting cold, but I was unable to proceed except by jerks. Once I

got arrested, my feet in a muddy pool. One foot was lifted to go, knowing that it was not good to be standing in water, but there I was fast, the cause of detention being the discussing with myself the reasons why I should not stand in that pool."—T. S. CLOUSTON, quoted by JAMES in *Psychology*, vol. ii, ch. 21, p. 284. (H. H. & Co., 1899.)

905. DOUBT CONSECRATED BY DESCARTES—*His Search Still for Certainty.*—The central propositions of the whole "Discourse" [of Descartes on "The Right Use of the Reason"] are these: There is a path that leads to truth so surely that any one who will follow it must needs reach the goal, whether his capacity be great or small. And there is one guiding rule by which a man may always find this path, and keep himself from straying when he has found it. This golden rule is—give unqualified assent to no propositions but those the truth of which is so clear and distinct that they cannot be doubted. The enunciation of this great first commandment of science consecrated doubt. . . . When I say that Descartes consecrated doubt, you must remember that it was that sort of doubt which Goethe has called "the active skepticism, whose whole aim is to conquer itself"; and not that other sort which is born of flippancy and ignorance, and whose aim is only to perpetuate itself, as an excuse for idleness and indifference. But it is impossible to define what is meant by scientific doubt better than in Descartes's own words. After describing the gradual progress of his negative criticism, he tells us: "For all that, I did not imitate the skeptics, who doubt only for doubting's sake, and pretend to be always undecided; on the contrary, my whole intention was to arrive at certainty, and to dig away the drift and the sand until I reached the rock or the clay beneath."—HUXLEY *Lay Sermons*, serm. 14, p. 323. (G. P. P., 1899.)

906. DREAD OF THE IRREVOCABLE—*An Undecided Character.*—Against this impulse [to act and end suspense] we have the dread of the irrevocable, which often engenders a type of character incapable of prompt and vigorous resolve, except perhaps when surprised into sudden activity. These two opposing motives twine round whatever other motives may be present at the moment when decision is imminent, and tend to precipitate or retard it. The conflict of these motives so far as they alone affect the matter of decision is a conflict as to when it shall occur. One says "now," the other says "not yet."—JAMES *Psychology*, vol. ii, ch. 26, p. 530. (H. H. & Co., 1899.)

907. DREAM A BRIEF INSANITY—*Dreamer Has the Corrective of Waking—The Normal Mind Restored by Touch of External World.*—The parallelism between dreams and insanity has been pointed out by most writers on the subject. Kant observed that the madman is a dreamer awake, and more recently Wundt has remarked that, when asleep, we "can experience nearly all the phenomena which meet us in lunatic asylums." The grotesqueness of the combinations, the lack of all judgment as to consistency, fitness, and probability, are common characteristics of the short night-dream of the healthy and the long day-dream of the insane. But one great difference marks off the two domains. When dreaming, we are still sane, and shall soon prove our sanity. After all, the dream of the sleeper is corrected, if not so rapidly as the illusion of the healthy waker. As soon as the familiar stimuli of light and sound set the peripheral sense-organs in activity, and call back the nervous system to its complete round of healthy action, the illusion disappears, and we smile at our alarms and agonies, saying, "Behold, it was a dream!"—SULLY *Illusions*, ch. 7, p. 182. (A., 1897.)

908. DREAM-LIFE INFLUENCES OUR WAKING HOURS—Thus, Paul Radestock, in the work "Schlaf und Traum" [Sleep and Dream], tells us: "When I have been taking a walk, with my thoughts quite unfettered, the idea has often occurred to me that I had seen, heard, or thought of this or that thing once before, without being able to recall when, where, and in what circumstances. This happened at the time when, with a view to the publication of the present work, I was in the habit of keeping an exact record of my dreams. Consequently I was able to turn to this after these impressions, and on doing so I generally found the conjecture confirmed that I had previously dreamed something like it." Scientific inquiry is often said to destroy all beautiful thoughts about Nature and life; but while it destroys it creates. Is it not almost a romantic idea that just as our waking life images itself in our dreams, so our dream-life may send back some of its shadowy phantoms into our prosaic every-day world, touching this with something of its own weird beauty?—SULLY *Illusions*, ch. 10, p. 275. (A., 1897.)

909. DRUDGERY OF ENGINE-ROOM LESSENED—*The Mechanical Stoker.*—For a good many years mechanical stokers have been devised in various forms: they are steadily coming into favor in improved and economical types, completing the modernization of fuel-burning, and abolishing a most oppressive form of drudgery. As the automatic hopper, filled with fine coal, glides to and fro above a furnace provided with moving grate-bars, we behold the latest term of that marvelous advance which began when the savage first laboriously kindled a blaze to warm his hands or to cook his breakfast.—ILES *Flame, Electricity, and the Camera*, ch. 5, p. 6. (D. & McC., 1900.)

910. DUALISM OF PLATO AND MILL—*Calvinism Truer to Scientific Thought.*—Now in these strong assertions it seems to me that the Calvinist is much more nearly

in accord with our modern knowledge than are Plato and Mill. It is not wise to hazard statements as to what the future may bring forth, but I do not see how the dualism implied in all these attempts to refer good and evil to different creative sources can ever be seriously maintained again. The advance of modern science carries us irresistibly to what some German philosophers call monism, but I prefer to call it monotheism.—FISKE *Through Nature to God*, pt. i, ch. 4, p. 22. (H. M. & Co., 1900.)

911. DUALITY OF THE MIND—*A Beneficent Delusion.*—A gentleman of respectable birth, excellent education, and ample fortune, engaged in one of the highest departments of trade, . . . and being induced to embark in one of the plausible speculations of the day . . . was utterly ruined. Like other men, he could bear a sudden overwhelming reverse better than a long succession of petty misfortunes, and the way in which he conducted himself on the occasion met with unbounded admiration from his friends. He withdrew, however, into rigid seclusion, and being no longer able to exercise the generosity and indulge the benevolent feelings which had formed the happiness of his life, made himself a substitute for them by day-dreams, gradually fell into a state of irritable despondency, from which he only gradually recovered with the loss of reason. He now fancied himself possessed of immense wealth, and gave without stint his imaginary riches. He has ever since been under gentle restraint, and leads a life not merely of happiness, but of bliss; converses rationally, reads the newspapers, where every tale of distress attracts his notice, and being furnished with an abundant supply of blank checks, he fills up one of them with a munificent sum, sends it off to the sufferer, and sits down to his dinner with a happy conviction that he has earned the right to a little indulgence in the pleasures of the table; and yet, on a serious conversation with one of his old friends, he is quite conscious of his real position, but the conviction is so exquisitely painful that he will not let himself believe it.—WIGAN *Duality of the Mind*, quoted by JAMES in *Psychology*, vol. ii, ch. 26, p. 567. (H. H. & Co., 1899.)

912. DURATION OF LIFE OF ANTS—*Science Reverses Popular Estimate—Value of Experiment.*—I have already mentioned that the previous views as to the duration of life of ants turn out to be quite erroneous. It was the general opinion that they lived for a single year. Two of my queen ants lived, the one nearly fourteen, the other nearly fifteen years, viz., from December, 1874, to July, 1887, and August, 1888, respectively. During the whole time they enjoyed perfect health, and every year have laid eggs producing workers, a fact which suggests physiological conclusions of great interest. I have, moreover, little doubt that some of the workers now in this nest were among those originally captured, the mortality after the first few weeks having been but small. This, however, I cannot prove.—AVEBURY *Ants, Bees, and Wasps*, ch. 2, p. 41. (A., 1900.)

913. DURATIONS OF THE CELESTIAL PERIODS—*Millions of Ages Are But Seconds of the Eternal Clock.*—These durations of celestial periods exceed the ordinary idea of time which man has when he wonders at the age of a centenarian. These sidereal events, which are only reproduced after thousands of centuries, and which appear to us very rare occurrences, are, on the contrary, frequent phenomena of eternity. These periods of millions of ages are but the seconds of the eternal clock.—FLAMMARION *Popular Astronomy*, p. 45. (A.)

914. DUST A SOURCE OF BEAUTY AND FERTILITY—*Tints of Spring and Autumnal Skies—Rain Brings Fertility from Heaven.*—In spring we have a bluer sky and greater transparency of the atmosphere; in autumn, even on very fine days, there is always a kind of yellowish haze, resulting in a want of clearness in the air and purity of color in the sky. These phenomena are quite intelligible when we consider that during winter less dust is formed, and more is brought down to the earth by rain and snow, resulting in the transparent atmosphere of spring, while exactly opposite conditions during summer bring about the mellow autumnal light. Again, the well-known beneficial effects of rain on vegetation—as compared with any amount of artificial watering, tho no doubt largely due to the minute quantity of ammonia which the rain brings down with it from the air—must yet be partly derived from the organic or mineral particles which serve as the nuclei of every raindrop, and which, being so minute, are more readily dissolved in the soil and appropriated as nourishment by the roots of plants.—WALLACE *The Wonderful Century*, ch. 9, p. 84. (D. M. & Co., 1899.)

915. DUST MAKES PATH OF SUNBEAM VISIBLE—Every one has seen the floating dust in a sunbeam when sunshine enters a partially darkened room; but it is not generally known that if there was absolutely no dust in the air the path of the sunbeam would be totally black and invisible, while if only very little dust was present in very minute particles the air would be as blue as a summer sky.—WALLACE *The Wonderful Century*, ch. 9, p. 70. (D. M. & Co., 1899.)

916. DUST OF MOUNTAINS—*Glacier Grinds Rocks to Powder—Blue of Alpine Lake.*—The rocks over which glaciers pass are finely ground and pulverized by the ice, or the stony emery embedded in it; and the river which issues from the snout of every glacier is laden with suspended matter. When such glacier-water is placed in a tall

glass jar, and the heavier particles are permitted to subside, the liquid column, when viewed against a dark background, has a decidedly bluish tinge. The exceptional blueness of the Lake of Geneva, which is fed with glacier-water, may be due, in part, to particles small enough to remain suspended long after their larger and heavier companions have sunk to the bottom of the lake. —TYNDALL *Fragments of Science*, vol. i, ch. 5, p. 137. (A., 1897.)

917. DUST OF THE AIR PROVED TO BE ORGANIC—*Germs in the Air a Cause of Disease.*—It was Tyndall who first laid down the general principles upon which our knowledge of organisms in the air is based. That the dust in the air was mainly organic matter, living or dead, was a comparatively new truth; that epidemic disease was not due to "bad air" and "foul drains," but to germs conveyed in the air, was a prophecy as daring as it was correct. From these and other like investigations it came to be recognized that putrefaction begins as soon as bacteria gain an entrance to the putrefiable substance, that it progresses in direct proportion to the multiplication of bacteria, and that it is retarded when they diminish or lose vitality.—NEWMAN *Bacteria*, ch. 3, p. 101. (G. P. P., 1899.)

918. DUST ON HIGHEST MOUNTAINS—*Granular Snow or Névé.*—The névé is composed of stratified granular snow which is white or grayish white in color. The snow on high mountains is apt to be exceedingly fine, light, and dry when first formed; but by partial melting and refreezing it acquires a coarse, granular texture, much like compacted hail, and also becomes consolidated and hard. The surface of the névé is many times so softened by the warmth between summer storms that a thin crust of ice is formed when the temperature is again lowered. This crust is buried beneath the next succeeding snowfall and remains in the growing deposit as a thin stratum of ice. Névés are almost entirely free from stones or dirt, altho even on the highest mountains the dust borne from naked cliffs is widely spread over their surfaces and diminishes their brilliancy. This general dust-covering is frequently not noticeable until some really clean snow surface is brought in contrast with it. When a lake on the névé is drained and leaves a fresh surface of dazzling whiteness, the surrounding area frequently shows a gray tint by contrast, thus revealing the presence of dust which has been sprinkled over it. Sometimes the covering of dust, especially on the lower portions of the névés of Alpine glaciers, is sufficiently pronounced to form a definite division plane when buried by subsequent snowfalls. Illustrations of such an occurrence may frequently be seen in the walls of fissures.—RUSSELL *Glaciers of North America*, int., p. 4. (G. & Co., 1897.)

919. DUST ON THE HIGH SEAS—*Volcanic Products Carried Afar.*—The very finely divided volcanic dust is often borne to enormous distances from the volcano out of which it has been ejected. The force of the steam-current carrying the fragments into the atmosphere is often so great that they rise to the height of several miles above the mountain. Here they may actually pass into the upper currents of the atmosphere and be borne away to the distance of many hundreds or thousands of miles. Hence it is not an unusual circumstance for vessels at sea to encounter at great distances from land falling showers of this finely divided, volcanic dust.—JUDD *Volcanoes*, ch. 4, p. 71. (A., 1899.)

920. DUST, VOLCANIC—*Carried Round the World—Skies Long Reddened by Reflection—Eruption of Krakatau.*—A remarkable confirmation of this theory was given during the two or three years after the great eruption of Krakatau, near Java. The volcanic débris was shot up from the crater many miles high, and the heavier portion of it fell upon the sea for several hundred miles around, and was found to be mainly composed of very thin flakes of volcanic glass. Much of this was of course ground to impalpable dust by the violence of the discharge, and was carried up to a height of many miles. Here it was caught by the return current of air continually flowing northward and southward above the equatorial zone; and as these currents reach the temperate zone where the surface rotation of the earth is less rapid they continually flow eastward, and the fine dust was thus carried at a great altitude completely round the earth. Its effects were traced some months after the eruption in the appearance of brilliant sunset glows of an exceptional character, often flushing with crimson the whole western half of the visible sky. These glows continued in diminishing splendor for about three years, they were seen all over the temperate zone; and it was calculated that, before they finally disappeared, some of this fine dust must have traveled three times round the globe.—WALLACE *The Wonderful Century*, ch. 9, p. 77. (D. M. & Co., 1899.)

921. ——— ——— *Vast Quantity—Incalculable Minuteness.*—Mr. Whymper relates that, while standing on the summit of Chimborazo, he witnessed an eruption of Cotopaxi, which is distant more than fifty miles from the former mountain. The fine volcanic dust fell in great quantities around him, and he estimated that no less than two millions of tons must have been ejected during this slight outburst. Professor Bonney has examined this volcanic dust from Cotopaxi, and calculates that it would take from 4,000 to 25,000 particles to make up a grain in weight.—JUDD *Volcanoes*, ch. 4, p. 69. (A., 1899.)

922. DUTY TO HUMANITY—*Conquests of Science Belong to the Race.*—I hold it to be the duty of naturalists, not merely to meditate upon improvements and discoveries in the narrow circle to which their specialty confines them, not merely to pore over their one study with love and care, but also to seek to make the important general results of it fruitful to the mass, and to assist in spreading the knowledge of physical science among the people. The highest triumph of the human mind, the true knowledge of the most general laws of Nature, ought not to remain the private possession of a privileged class of learned men, but ought to become the common property of all mankind.—HAECKEL *History of Creation*, vol. i, ch. 1, p. 4. (K. P. & Co., 1899.)

923. DWELLINGS DEFENSIBLE—*Home of the Trap-door Spider.*—Trap-door spiders display the curious instinct of providing their nests with trap-doors. The nest consists of a tube excavated in the earth to the depth of half a foot or more. In all save one species the tube is unbranched; it is always lined with silk, which is continuous with the lining of the trap-doors, of which it forms the hinge. In the species which constructs a branching tube, the branch is always single, more or less straight, takes origin at a point situated a few inches from the orifice of the main tube, is directed upwards at an acute angle with that tube, and terminates blindly just below the surface of the soil. At its point of junction with or departure from the main tube it is provided with a trap-door resembling that which closes the orifice of the main tube, and of such a size and arrangement that when closed against the opening of the branch tube it just fills that opening; while when turned outwards, so as to uncork this opening, it just fills the diameter of the main tube: the latter, therefore, is in this species provided with two trap-doors, one at the surface of the soil, and the other at the fork of the branched tube.—ROMANES *Animal Intelligence*, ch. 6, p. 213. (A., 1899.)

924. DWELLINGS, ELEVATED, MOST HEALTHFUL—*Babylonians Built on Artificial Mounds.*—It was Hippocrates, head master of the art of healing, who pointed out that elevated situations are more advantageous as the site of dwellings than the low, and that the Babylonians who built in the valleys of rivers, or on other low ground, as a rule erected their dwellings upon artificial mounds.—ALSBERG *Die gesunde Wohnung.* (Translated for *Scientific Side-Lights.*)

925. DYING-PLACE OF A RACE—*The Huanacos' Golgotha.*—It is well known that at the southern extremity of Patagonia the huanacos have a dying-place, a spot to which all individuals inhabiting the surrounding plains repair at the approach of death to deposit their bones. Darwin and Fitzroy first recorded this strange instinct in their personal narratives, and their observations have since been fully confirmed by others. The best known of these dying- or burial-places are on the banks of the Santa Cruz and Gallegos rivers, where the river valleys are covered with dense primeval thickets of bushes and trees of stunted growth; there the ground is covered with the bones of countless dead generations. "The animals," says Darwin, "in most cases must have crawled, before dying, beneath and among the bushes." A strange instinct in a creature so preeminently social in its habits: a dweller all its life long on the open, barren plateaux and mountainsides! What a subject for a painter! The gray wilderness of dwarf thorn-trees, aged and grotesque and scanty-leaved, nourished for a thousand years on the bones that whiten the stony ground at their roots; the interior lit faintly with the rays of the departing sun, chill and gray, and silent and motionless—the huanacos' Golgotha.—HUDSON *Naturalist in La Plata*, ch. 21, p. 316. (C. & H., 1895.)

926. EARNESTNESS OF SCIENCE—*Reaching toward the Infinite.*—The great and solemn spirit that pervades the intellectual labor [of science] arises from the sublime consciousness of striving toward the infinite, and of grasping all that is revealed to us amid the boundless and inexhaustible fulness of creation, development, and being. This active striving, which has existed in all ages, must frequently, and under various forms, have deluded men into the idea that they had reached the goal, and discovered the principle which could explain all that is variable in the organic world, and all the phenomena revealed to us by sensuous perception.—HUMBOLDT *Cosmos*, vol. iii, p. 11. (H., 1897.)

927. EARTH A MAGNET—*Revolution of Magnetic Pole.*—One of the striking exhibitions of magnetism is found in the earth. The earth itself is a great magnet; and there is good reason for believing that it is an electromagnet of great power. The magnetic poles of the earth are not exactly coincident with the geographical poles, and they are not constant. There is a gradual deviation going on, but as it follows a certain law mariners are able to tell just what the deviation should be at a certain time. The magnetic pole revolves around the polar axis of the earth once in about 320 years.—ELISHA GRAY *Nature's Miracles*, vol. iii, ch. 4, p. 32. (F. H. & H., 1900.)

928. EARTH AS VIEWED FROM WITHOUT—*An Imaginary Description by a Scientist of the Moon.*—The academicians of the moon doubtless say, in their turn, with an assurance no less convinced, "The earth is composed of elements dissimilar and very extraordinary. One, which forms the nucleus of the body and which gives birth to fixed spots, appears to have some consist

ency; but it is covered with another element, of a strange constitution, which appears to have neither body, nor stability, nor continuance. It has neither color nor density. It takes all forms, moves in all directions, obeys all shocks, submits to all impulses, is extended, contracted, condensed, appears and disappears, without our being able to imagine such strange metamorphoses. This is the world of instability, the planet of revolutions. It experiences in turn all imaginable disasters. It seems to be matter in fermentation, which tends to dissolve. We only see storms, cyclones, whirlwinds, and acts of violence of all sorts. They assert that there are inhabitants on this planet; but on what point can they live? Is it on the solid element of the body? They would be crushed, suffocated, asphyxiated, drowned by that element which weighs on them from all sides. Is it through the openings in this mobile curtain that they can enjoy, as we do, the pure ether of the heavens? But how can we suppose that they might not at any moment be torn from the soil by the violence of the disorders which torment the surface? Do they wish to place them on the light and mobile stratum which hides from us so often the aspect of the terrestrial nucleus? How can they be maintained upright on this element without solidity? . . . There is no necessity for long consideration to prove conclusively that this planet is very vast, but that it is no place for animated beings. The whole earth is not worth the soul of a single Selenite. If, however, they will insist that it may have inhabitants, we will consent with pleasure, provided that they compare them with fantastic beings floating at the pleasure of all the forces which contend with each other on this aeriform planet. There can only exist there rather coarse animals. Such are, in our opinion, the only inhabitants which can people the earth."

The scientists of the moon have, as we see, the ability to prove, in the most categorical manner, to the ignorant who surround them, that the earth, not being habitable, should not be inhabited, and that it is made solely to serve as a clock to the moon and to shine during the night.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 6, p. 159. (A.)

929. EARTH, CONVULSIONS OF—*Ancient and Modern Catastrophes Compared.*—We know that subterranean movements and volcanic eruptions are often attended not only by incursions of the sea, but also by violent rains, and the complete derangement of the river-drainage of the inland country, and by the damming up of the outlets of lakes by landslips, or obstructions in the courses of subterranean rivers, such as abound in Thessaly and the Morea. We need not therefore be surprised at the variety of causes assigned for the traditional floods of Greece, by Herodotus, Aristotle, Diodorus, Strabo, and others. As to the area embraced, had all the Grecian deluges occurred simultaneously, instead of being spread over many centuries, and had they, instead of being extremely local, reached at once from the Euxine to the southwestern limit of the Peloponnesus, and from Macedonia to Rhodes, the devastation would still have been more limited than that which visited Chile in 1835, when a volcanic eruption broke out in the Andes, opposite Chiloe, and another at Juan Fernandez, distant 720 geographical miles, at the same time that several lofty cones in the Cordillera, 400 miles to the eastward of that island, threw out vapor and ignited matter. Throughout a great part of the space thus recently shaken in South America, cities were laid in ruins, or the land was permanently upheaved, or mountainous waves rolled inland from the Pacific.—LYELL *Principles of Geology*, bk. ii, ch. 22, p. 357. (A., 1854.)

930. EARTH, COOLING AND CONTRACTION OF—*Earthquakes and Volcanoes Mightier in Early Times.*—The general result which we should arrive at would be that in past ages the loss of heat was more rapid than it is at present. Now the contraction of a body as it cools is for low temperatures proportional to its loss of heat, and this law is also probably true for contraction as it takes place from high temperatures. Contraction of the earth's nucleus being more rapid than it is at present, it is probable that phenomena like elevations and depressions would be more rapid than they are at present, and generally all changes due to Plutonic action, as has already been pointed out by Lord Kelvin (Sir William Thomson), must have been more frequent and intense than they are at the present day. We have, therefore, every reason to imagine that earthquakes which belong to the category of phenomena here referred to were also numerous and occurred on a grander scale during the earlier stages of the world's history than they do at present, and seismic and volcanic energy, when considered in reference to long periods of time, is probably a decreasing energy.—MILNE *Earthquakes*, ch. 13, p. 236. (A., 1899.)

931. EARTH, DESTRUCTION AND RENOVATION OF ITS SURFACE—*Theory of Aristotle.* — When we consider the acquaintance displayed by Aristotle, in his various works, with the destroying and renovating powers of Nature, the introductory and concluding passages of the twelfth chapter of his "Meteorics" are certainly very remarkable. In the first sentence he says, "The distribution of land and sea in particular regions does not endure throughout all time, but it becomes sea in those parts where it was land, and again it becomes land where it was sea: and there is reason for thinking that these changes take place according to a certain system, and within a certain period." The concluding observation

is as follows: "As time never fails, and the universe is eternal, neither the Tanais nor the Nile can have flowed forever. The places where they rise were once dry, and there is a limit to their operations; but there is none to time. So also of all other rivers; they spring up, and they perish; and the sea also continually deserts some lands and invades others. The same tracts, therefore, of the earth are not some always sea, and others always continents, but everything changes in the course of time."—LYELL *Principles of Geology*, bk. i, ch. 2, p. 13. (A., 1854.)

932. EARTH, ELEVATION AND SUBSIDENCE OF—*Slow Movement through Centuries.*—Lyell estimated that the average rate of rise in Scandinavia has been about two and a half feet per century. At the North Cape the rise may have been as much as five or six feet per century. Observations made at the temple of Jupiter Serapis, between October, 1822, and July, 1838, showed that the ground was sinking at the rate of about one inch in four years. Since the Roman period, when this temple was built, the ground has sunk twenty feet below the waves. Now the floor of the temple is on the level of the sea. Lyell remarks that if we reflect on the dates of the principal oscillations at this place there appears to be connection between the movements of upheaval and a local development of volcanic heat, whilst periods of depression are concurrent with periods of volcanic quiescence.—MILNE *Earthquakes*, ch. 21, p. 351. (A., 1899.)

933. EARTH ENRICHED BY MATERIALS FROM AFAR—*Matter from Distant Space Continually Drawn In.*—Let it suffice that we recognize, as one of the earliest stages of our earth's history, her condition as a rotating mass of glowing vapor, capturing then as now, but far more actively then than now, masses of matter which approached near enough, and growing by these continual indrafts from without. From the very beginning, as it would seem, the earth grew in this way. This firm earth on which we live represents an aggregation of matter not from one portion of space, but from all space. All this is upon and within the earth, all vegetable forms and all animal forms, our bodies, our brains, are formed of materials which have been drawn in from those depths of space surrounding us on all sides. This hand that I am now raising contains particles which have traveled hither from regions far away amid the northern and southern constellations, particles drawn in towards the earth by processes continuing millions of millions of ages, until after multitudinous changes the chapter of accidents has so combined them, and so disturbed them in plants and animals, that after coming to form portions of my food they are here present before you. Passing from the mere illustration of the thought, is not the thought itself striking and suggestive, that not only the earth on which we move, but everything we see or touch, and every particle in body and brain, has sped during countless ages through the immensity of space?—PROCTOR *Our Place among Infinities*, p. 9. (L. G. & Co., 1897.)

934. EARTH FEELS CHANGES ON SUN—*Cosmic Influence—Auroras Follow Variation of Sun-spots.*—The relation between the aurora borealis and the sun-spots was studied and finally proved by Fritz, Loomis, and Lovering. Fritz appears to have been the first who distinctly laid down the law that the number and importance of the auroras follow exactly the same variation as the spots on the sun, so that the epochs of the maxima and minima coincide almost exactly for the two orders of phenomena.—ANGOT *Aurora Borealis*, ch. 5, p. 96. (A., 1897.)

935. EARTH FORMING STILL—*Ceaseless Circulation of the Solid Materials of the Globe.*—Over every part of the earth's surface these three grand operations of the disintegration of old rock-masses, the transport of the materials so produced to lower levels, and the accumulation of these materials to form new rocks, are continually going on. It is by the varied action of these denuding agents upon rocks of unequal hardness, occupying different positions in relation to one another, that all the external features of hills, and plains, and mountains owe their origin.—JUDD *Volcanoes*, ch. 10, p. 284. (A., 1899.)

936. EARTH HELD TO BE A GREAT METEORITE—But in recent years a number of very important facts have been discovered which may well lead us to devote a closer attention to the composition and structure of meteorites. It has been shown, on the one hand, that some meteorites contain substances precisely similar to those which are sometimes brought from the earth's interior during volcanic outbursts; and, on the other hand, there have been detected, among some of the ejections of volcanoes, bodies which so closely resemble meteorites that they were long mistaken for them. Both kinds of observation seem to point to the conclusion that the earth's interior is composed of similar materials to those which we find in the small planets called meteorites.—JUDD *Volcanoes*, ch. 11, p. 315. (A., 1899.)

937. EARTH, HUMAN DWELLINGS ENGULFED IN—*Fissures Opened and Closed in Earthquake.*—Almost all large earthquakes have produced cracks in the ground. The cracks which were found in the ground at Yokohama (February 22, 1880) were about two or three inches wide, and from twenty to forty yards in length. They could be best seen as lines along a road running near the upper edge of some cliffs which overlook the sea at that place. The reason

that cracks should have occurred in such a position rather than in others was probably owing to the greater motion at such a place, due to the face of the cliff being unsupported, and there being no resistance opposed to its forward motion. It often happens that earthquake cracks are many feet in width. At the Calabrian earthquake of 1783, one or two of the crevasses which were formed were more than 100 feet in width and 200 feet in depth. Their lengths varied from half a mile to a mile. Besides these large cracks, many smaller ones of one or two feet in breadth and of great length were formed. In the large fissures many houses were engulfed. Subsequent excavations showed that by the closing of the fissures these had been jammed together to form one compact mass.—MILNE *Earthquakes*, ch. 8, p. 147. (A., 1899.)

938. EARTH, LONG DURATION OF —*Coral Reefs Require Vast Periods of Time —Contrasted Brevity of Human Life.*—The evidence capable of being adduced from the growth of coral reefs goes far to prove the constant and uniform state of our earth throughout immense periods of time. The testimony of Mr. Dana with regard to the rate at which coral grows is to the effect that the massive corals on which the increase of reef depends are of very slow growth; the branching and certain other kinds growing at a faster rate. One-eighth of an inch per year is given by this author as "the average upward increase of the whole reef-ground per year"; and the estimate appears to be a perfectly just one, when judged by the evidence afforded us of the rate of growth in corals. All authorities agree in stating the growth of massive corals at a very low rate, and the time which has been occupied in the formation of a reef 2,000 feet thick must, therefore, on Mr. Dana's estimate, be set down at 192,000 years. This computation, it must be remembered, is one dealing with the work of modern corals. In the far-back past, coral reefs existed similar in every respect to their modern representatives; these fossil reefs in many cases evincing an immense thickness. Hence we are led to believe that, notwithstanding the alteration which our earth has undergone, it has had prolonged periods of rest; and the existence of a modern coral reef may therefore afford evidence, not only of the immensity of past time, but also of the uniformity of Nature's ways and works during periods compared with which the farthest limits of history and even of man's own age are but as yesterday.—WILSON *Facts and Fictions of Zoology*, p. 43. (Hum., 1882.)

939. EARTH LOSING HEAT—*Change and Upbuilding of Surface to Cease—The Planet's Old Age.*—The earth's nuclear regions are parting with their heat, and as they cannot part with their heat without warming the surface-crust, which nevertheless grows no warmer, we perceive that the surface-heat is maintained from a source which is being gradually exhausted. The fitness of the earth to be the abode of life will not only be affected directly in this way, but will be indirectly affected by the loss of that Vulcanian energy which appears to be one of its necessary conditions. At present, the surface of the earth is like the flesh clothing the living body; it does not wear out because (through the life which is within it) it undergoes continual change. But even as the body itself is consumed by natural processes so soon as life has passed from it, so when the internal heat of the earth, which is its life, shall have passed away, her surface will "grow old as doth a garment" (Ps. cii, 26); and with this inherent terrestrial vitality will pass away by slow degrees the life which is upon the earth.—PROCTOR *Our Place among Infinities*, p. 28. (L. G. & Co., 1897.)

940. EARTH ONCE A MOLTEN MASS —There was a time when our earth was in a state of igneous fusion, when no ocean bathed it and no atmosphere surrounded it, when no wind blew over it and no rain fell upon it, but an intense heat held all its materials in solution. In those days the rocks which are now the very bones and sinews of our mother earth—her granites, her porphyries, her basalts, her syenites—were melted into a liquid mass. — AGASSIZ *Geological Sketches*, ser. i, ch. 1, p. 2. (H. M. & Co., 1896.)

941. EARTH, THE FINISHING OF, FOR MAN—The work of the artist is not yet finished when his statue is blocked out and the grand outline of his conception stands complete: and there still remained, after the earth was rescued from the water, after her framework of mountains was erected, after her soil was clothed with field and forest, processes by which her valleys were to be made more fruitful, her gulfs to be filled with the rich detritus poured into them by the rivers, her whole surface to be rendered more habitable for the higher races who were to possess it.—AGASSIZ *Geological Sketches*, ser. i, ch. 7, p. 204. (H. M. & Co., 1896.)

942. EARTH UNINHABITABLE WITHOUT BIRDS—*Our Unconsidered Indebtedness.*—If we were deprived of the services of birds [in the destruction of insects], the earth would soon become uninhabitable. Nevertheless, the feathered protectors of our farms and gardens, plains and forests, require so little encouragement from us—indeed, ask only tolerance—that we accept their services much as we do the air we breathe. We may be in debt to them past reckoning, and still be unaware of their existence.—CHAPMAN *Bird-Life*, ch. 1, p. 9. (A., 1900.)

943. EARTH'S ANCIENT COMPANION—*The Moon an Object of Unique Interest to Man.*—The moon possesses for us an

unique interest. She in all probability shared the origin of the earth; she perhaps profigures its decay. She is at present its minister and companion. Her existence, so far as we can see, serves no other purpose than to illuminate the darkness of terrestrial nights, and to measure, by swiftly recurring and conspicuous changes of aspect, the long span of terrestrial time. Inquiries stimulated by visible dependence, and aided by relatively close vicinity, have resulted in a wonderfully minute acquaintance with the features of the single lunar hemisphere open to our inspection.—CLERKE *History of Astronomy*, pt. ii, ch. 7, p. 322. (Bl., 1893.)

944. EARTH'S GIRDLE—*Electric Telegraph—Submarine Lines of Telegraph.*—About the middle of the last century it was perceived by a few students of electricity that it afforded a means of communication at a distance; but it was not till the year 1837 that the efforts of many simultaneous workers overcame the numerous practical difficulties, and the first electric telegraph was established. Its utility was so great, especially in the working of the railways then being rapidly extended over the kingdom, that it soon came into general use. The first submarine line was laid from Dover to Calais in 1851; and only five years afterward, in 1856, a company was formed to lay an electric cable across the Atlantic. The cable, 2,500 miles long and weighing a ton per mile, was successfully laid, in 1858, from Ireland to Newfoundland; but owing to the weakness of the electric current, and perhaps to imperfections in the cable, it soon became useless, and had to be abandoned. After eight years more of invention and experiment, another cable was successfully laid in 1866; and there are now no less than fourteen lines across the Atlantic, while all the other oceans have been electrically bridged, so that messages can be sent to almost any part of the globe at a speed which far surpasses the imaginary power of Shakespeare's sprite Ariel, who boasted that he could "put a 'girdle round about' the earth in forty minutes"—WALLACE *The Wonderful Century*, ch. 3, p. 21. (D. M. & Co., 1899.)

945. EARTH'S RETURNING FRAGMENTS—*Meteorites Perhaps of Earthly Origin.*—Well, these stones from the sky being of the same composition as the minerals of which our own planet is formed, is it not natural to ask simply whether they may not have had the earth itself for their origin? But how? May not the violent volcanoes of geological times, the eruptions, the tremendous conflagrations, the fierce fires of the ancient pandemonium, have shot into space lava, scoria, stones, with such a force of projection that these objects would be despatched to thousands, millions, hundreds of millions of miles, in orbits which would not take less than a thousand, ten thousand, a hundred thousand years or more to describe? If our planet has been able to give birth to such projectiles, it does not form an exception in the universe, and the other celestial bodies may be in the same case. Thus, the sun itself is seen to be almost constantly surrounded with tremendous metallic gaseous eruptions, which are shot out to thousands and even hundreds of thousands of miles above its surface. This is the most rational hypothesis. Such eruptions may take place on all worlds. However, the terrestrial eruptions would make the products return to us, whereas the others would be sent in all directions. Moreover, the identity of structure of most of the uranoliths with terrestrial minerals presents itself as an eloquent witness in favor of this hypothesis, which may be summed up thus:

Most of the stones which fall from the sky may be natives of the earth itself, having been projected into space by the volcanic eruptions of geological times.—FLAMMARION *Popular Astronomy*, bk. v, ch. 4, p. 549. (A.)

946. EARTH'S SWIFT REVOLUTION—*The Sun's Ceaseless Control.*—If the earth could be suddenly stopped in her orbit, and allowed to fall unobstructed toward the sun under the accelerating influence of his attraction, she would reach the center in about two months. I have said if she could be stopped, but such is the compass of her orbit that, to make its circuit in a year, she has to move nearly 19 miles a second, or more than fifty times faster than the swiftest rifle-ball; and in moving 20 miles her path deviates from perfect straightness by less than one-eighth of an inch. And yet, over all the circumference of this tremendous orbit, the sun exercises his dominion, and every pulsation of his surface receives its response from the subject earth.—YOUNG *The Sun*, ch. 1, p. 37. (A., 1898.)

947. EARTH-CRUST AFLOAT ON A PLASTIC OCEAN—*The Solid Center Has Different Revolution.*—Nevertheless, inasmuch as solidification would occur at the surface, where the radiation of heat would take place most rapidly, and as the descending solid matter would be gradually liquefied, it seems certain that for a long time the solid portions of the earth, tho not forming a solid crust, would occupy the exterior parts of the earth's globe. After a time, the whole globe would have so far cooled that a process of aggregation of solid matter around the center of the earth would take place. The matter so aggregated consisted probably of metallic and metalloidal compounds denser than the material forming the crust of the earth. Between the solid center and the solidifying crust there would be a shell of uncongealed matter, gradually diminishing in amount, but a portion probably retaining its liquid condition even to the present time, whether existing in isolated reservoirs, or whether, as Scrope opines, it forms still a continuous sheet sur-

rounding the solid nucleus. One strange fact of terrestrial magnetism may be mentioned in partial confirmation of the theory that the interior of the earth is of this nature—a great solid mass, separated from the solid crust by a viscous plastic ocean: the magnetic poles of the earth are changing in position in a manner which seems only explicable on the supposition that there is an interior solid globe rotating under the outer shell, but at a slightly different rate, gaining or losing one complete rotation in the course of about 650 years.—PROCTOR *Our Place among Infinities*, p. 17. (L. G. & Co., 1897.)

948. EARTH-CRUST, CHANGES IN, CEASELESS—However constant may be the relative proportion of sea and land, we know that there is annually some small variation in their respective geographical positions, and that in every century the land is in some parts raised, and in others depressed in level, and so likewise is the bed of the sea. By these and other ceaseless changes, the configuration of the earth's surface has been remodeled again and again, since it was the habitation of organic beings, and the bed of the ocean has been lifted up to the height of some of the loftiest mountains.—LYELL *Principles of Geology*, bk. i, ch. 7, p. 102. (A., 1854.)

949. ——— ——— *Not Alarming—Relative Insignificance of Mountain Height.*—The imagination is apt to take alarm when called upon to admit the formation of such irregularities in the crust of the earth, after it had once become the habitation of living creatures; but, if time be allowed, the operation need not subvert the ordinary repose of Nature; and the result is in a general view insignificant, if we consider how slightly the highest mountain chains cause our globe to differ from a perfect sphere. Chimborazo, tho it rises to more than 21,000 feet above the sea, would be represented, on a globe of about six feet in diameter, by a grain of sand less than one-twentieth of an inch in thickness.

The superficial inequalities of the earth, then, may be deemed minute in quantity, and their distribution at any particular epoch must be regarded in geology as temporary peculiarities, like the height and outline of the cone of Vesuvius in the interval between two eruptions. But altho, in reference to the magnitude of the globe, the unevenness of the surface is so unimportant, it is on the position and direction of these small inequalities that the state of the atmosphere, and both the local and general climate, are mainly dependent.—LYELL *Principles of Geology*, bk. i, ch. 7, p. 102. (A., 1854.)

950. EARTH-CRUST UNDERMINED —*Caverns—Subterranean Rivers.*—In countries where calcareous rocks largely predominate, acidulated water filtering down from the surface through fissures and other division-planes has often licked out a complicated series of tortuous tunnels and galleries. So far has this process been carried on in some regions that the whole rainfall finds its way into subterranean courses, and the entire drainage of the land is conducted underground. The dimensions attained by many well-known limestone caverns, and the great width and depth of the channels through which subterranean rivers reach the sea, help us to appreciate the amount of rock-material which underground water is capable of removing. From the surface of certain regions hundreds of feet of various calcareous rocks have thus been gradually removed; while in other cases the contour of the ground has been notably affected by the collapse of underground channels and chambers.—GEIKIE *Earth Sculpture*, ch. 2, p. 31. (G. P. P., 1898.)

951. EARTH-LIGHT ON THE MOON —*The "Ashy Light"—Earth Sees Herself in the Mirror of the Moon.*—When the moon is a crescent, during the first days of the lunation, we notice that the rest of the lunar globe is visible, illuminated by a pale light. This is the *lumière cendrée* [the ashy light]. It is caused by the earth itself.

In fact, the earth is illuminated by the sun, and reflects the light into space. When the moon is in conjunction with the sun the earth is in "opposition," as seen from the moon; it is the epoch of full earth for an observer on our satellite. The light which our globe then sends to the moon exceeds about fourteen times that which the full moon sends to us. This ashy light, reflection of a reflection, resembles a mirror in which we may see the luminous state of the earth. In winter, when a great part of the terrestrial hemisphere is covered with snow, it is perceptibly brighter. Before the geographical discovery of Australia, astronomers suspected the existence of that continent from the ashy light, which was very much brighter than could be produced by the dark reflection from the ocean. This lunar light generally presents a greenish-blue tint, indicating that our planet, seen from a distance, would show this shade.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 2, p. 99. (A.)

952. EARTHQUAKE CHANGING LEVEL OF GROUND—*Houses and Persons Engulfed in Fissures.*—The soil of the Calabrian plains was found to be in some parts abnormally raised, in others as strangely depressed. "In the town of Terranova," says Sir Charles Lyell, "some houses were seen uplifted above the common level, and others adjoining sunk down into the earth. In several streets the soil appeared thrust up, and abutted against the walls of houses; a large circular tower of solid masonry, part of which withstood the general destruction, was divided by a circular rent, and one side was upraised, and the foundations heaved out of the ground." As might be expected, the soil did not continue unbroken by the

violent shocks to which it was subjected. In the central parts of the disturbed region the earth opened so widely as to swallow up large houses. In Cannamaria many buildings were "completely engulfed in one chasm," insomuch that not a trace of them was ever seen afterward. So violently did these chasms close their yawning jaws, that afterward, when excavations were made for the recovery of valuables, the workmen found the contents of houses crushed into a compact mass with detached portions of masonry. In some instances persons were engulfed by one shock and thrown out again alive by the following one.—PROCTOR *Notes on Earthquakes*, p. 3. (Hum., 1887.)

953. EARTHQUAKE DESOLATING WIDE DISTRICT—*Destruction, Sudden, Swift, and without Warning—Man Powerless in Grasp of Elemental Forces.*—One of the most remarkable earthquakes ever experienced was that which overthrew Riobamba on February 4, 1797. A district 120 miles long and 60 broad was shaken by an undulatory motion which lasted for four minutes, and a far wider district felt the effects of the disturbance. Within the space first named, in which the movement was more energetic, every town and village was leveled to the ground; and many places were buried under large masses flung down from the surrounding mountains. Among these was the flourishing town of Riobamba. Preceded and accompanied by no warning noises whatever, the terrific concussion in a few moments effected the complete desolation of the unhappy district. The earthquake was a singular combination of perpendicular, horizontal, and rotary vibrations. So violent was the perpendicular, or as it may be termed the explosive, movement, that hundreds of the wretched inhabitants were flung upon the hill La Culla, several hundred feet high, on the further side of the small river Lican. Then came a horizontal movement, so rapidly succeeding the other that in many instances the furniture of one house was found beneath the ruins of another. In some cases property was removed so far from its original place, that disputes arose among the survivors of the catastrophe, and the *Audiencia*, or court of justice, was for some time occupied in adjusting these difficulties. Not less remarkable were the effects of circular or rotary concussions. Walls beyond the town were twisted round without being flung down; rows of trees which had been parallel were deflected in the most remarkable manner; and the direction of the ridges of fields covered with various kinds of grain was observed to be altered by the effects of the earthquake.—PROCTOR *Notes on Earthquakes*, p. 4. (Hum., 1887.)

954. EARTHQUAKE IN THE MISSISSIPPI VALLEY—*Waves Traversing the Earth-crust—Chasms Opening Far and Wide—South Carolina and New Madrid, Missouri, 1811-12.*—Previous to the destruction of La Guayra and Caracas, in 1812, earthquakes were felt in South Carolina; and the shocks continued till those cities were destroyed. The valley also of the Mississippi, from the village of New Madrid to the mouth of the Ohio in one direction, and to the St. Francis in another, was convulsed in such a degree as to create new lakes and islands. It has been remarked by Humboldt in his "Cosmos," that the earthquake of New Madrid presents one of the few examples on record of the incessant quaking of the ground for several successive months far from any volcano. Flint, the geographer, who visited the country seven years after the event, informs us that a tract of many miles in extent, near the Little Prairie, became covered with water three or four feet deep; and when the water disappeared a stratum of sand was left in its place. Large lakes of twenty miles in extent were formed in the course of an hour, and others were drained. The graveyard at New Madrid was precipitated into the bed of the Mississippi; and it is stated that the ground whereon the town is built, and the river-bank for fifteen miles above, sank eight feet below their former level. The neighboring forest presented for some years afterwards "a singular scene of confusion; the trees standing inclined in every direction, and many having their trunks and branches broken."

The inhabitants relate that the earth rose in great undulations; and when these reached a certain fearful height, the soil burst, and vast volumes of water, sand, and pit-coal were discharged as high as the tops of the trees. Flint saw hundreds of these deep chasms remaining in an alluvial soil, seven years after. The people in the country, altho inexperienced in such convulsions, had remarked that the chasms in the earth were in a direction from southwest to northeast; and they accordingly felled the tallest trees, and laying them at right angles to the chasms, stationed themselves upon them. By this invention, when chasms opened more than once under these trees, several persons were prevented from being swallowed up. At one period during this earthquake, the ground not far below New Madrid swelled up so as to arrest the Mississippi in its course, and to cause a temporary reflux of its waves. The motion of some of the shocks is described as having been horizontal, and of others perpendicular; and the vertical movement is said to have been much less desolating than the horizontal.—LYELL *Principles of Geology*, bk. ii, ch. 27, p. 466. (A., 1854.)

955. EARTHQUAKE SHAKES MAN'S CONFIDENCE IN THE ORDER OF NATURE—*"The Solid Earth" Proved a Delusion.*—The deep and peculiar impression left on the mind by the first earthquake which we experience . . . is not, in my opinion, the result of a recollection of those fearful

pictures of devastation presented to our imaginations by the historical narratives of the past, but is rather due to the sudden revelation of the delusive nature of the inherent faith by which we had clung to a belief in the immobility of the solid parts of the earth. We are accustomed from early childhood to draw a contrast between the mobility of water and the immobility of the soil on which we tread; and this feeling is confirmed by the evidence of our senses. When, therefore, we suddenly feel the ground move beneath us, a mysterious and natural force, with which we are previously unacquainted, is revealed to us as an active disturbance of stability. A moment destroys the illusion of a whole life; our deceptive faith in the repose of Nature vanishes, and we feel transported, as it were, into a realm of unknown destructive forces. Every sound—the faintest motion in the air—arrests our attention, and we no longer trust the ground on which we stand. Animals, especially dogs and swine, participate in the same anxious disquietude; and even the crocodiles of the Orinoco, which are at other times as dumb as our little lizards, leave the trembling bed of the river, and run with loud cries into the adjacent forests. To man the earthquake conveys an idea of some universal and unlimited danger. We may flee from the crater of a volcano in active eruption, or from the dwelling whose destruction is threatened by the approach of the lava stream; but in an earthquake, direct our flight whithersoever we will, we still feel as if we trod upon the very focus of destruction.—HUMBOLDT *Cosmos*, vol. i, p. 215. (H., 1897.)

956. EARTHQUAKE'S WIDE-REACHING EFFECT—*Vast Destruction of Human Life.*—The great earthquake which destroyed the city of Lisbon on the 1st of November, 1755, was felt in the Alps, on the coast of Sweden, in the Antilles, Antigua, Barbados, and Martinique; in the great Canadian Lakes, in Thuringia, in the flat country of Northern Germany, and in the small inland lakes on the shores of the Baltic. Remote springs were interrupted in their flow, a phenomenon attending earthquakes which had been noticed among the ancients by Demetrius the Callatian. The hot springs of Töplitz dried up, and returned, inundating everything around, and having their waters colored with iron ocher. In Cadiz the sea rose to an elevation of sixty-four feet, while in the Antilles, where the tide usually rises only from twenty-six to twenty-eight inches, it suddenly rose above twenty feet, the water being of an inky blackness. It has been computed that on the 1st of November, 1755, a portion of the earth's surface, four times greater than that of Europe, was simultaneously shaken. As yet there is no manifestation of force known to us, including even the murderous inventions of our own race, by which a greater number of people have been killed in the short space of a few minutes: sixty thousand were destroyed in Sicily in 1693, from thirty to forty thousand in the earthquake of Riobamba in 1797, and probably five times as many in Asia Minor and Syria, under Tiberius and Justinian the elder, about the years 19 and 526.—HUMBOLDT *Cosmos*, vol. i, p. 211. (H., 1897.)

957. EARTHQUAKES, BENEFICENT EFFECTS OF—*Continents Maintained by Their Reproductive Power—Good from Seeming Evil.*—But for earthquakes our continents would continually—however slowly—diminish in extent through the action of the sea-waves upon their borders, and of rain and rivers on their interior surfaces. "Had the primeval world been constructed as it now exists," says Sir John Herschel, "time enough has elapsed, and force enough, directed to that end, has been in activity, to have long ago destroyed every vestige of land." It is to the reproductive energy of the earth's internal forces that we are alone indebted for the very existence of dry land. To the same cause, undoubtedly, we owe that gradual process of change in the configuration of continents and oceans which has been for ages and still is in progress—a process the benefit derived from which cannot possibly be called in question. Our forests and our fields derive their nourishment from soils prepared, for long ages, beneath the waves of ocean; our stores of coal and of many other important minerals have been in like manner prepared for our use during the long intervals of their submergence; we build our houses even with materials many of which owe their perfect adaptation to our wants to the manner in which they have been slowly deposited on what was once the bed of ocean, and compressed to a due solidity and firmness of texture beneath its depths. . . . So far from dreading lest the earth's subterranean forces should acquire new energies, we ought rather to fear lest they should lose their force.—PROCTOR *Notes on Earthquakes*, p. 6. (Hum., 1887.)

958. EARTHQUAKES, JAPANESE BUILDINGS UNHARMED BY—*Peril Accepted as a Common Incident of Life.*—The ordinary Japanese house consists of a light framework of 4- or 5-inch scantling, built together without struts or ties, all the timbers crossing each other at right angles. The spaces are filled in with wattlework of bamboo, and this is plastered over with mud. This construction stands on the top of a row of boulders or of square stones, driven into the surface soil to a distance varying from a few inches to a foot. The whole arrangement is so light that it is not an uncommon thing to see a large house rolled along from one position to another on wooden rollers. In buildings such as these, after a series of small earthquake shocks, we could hardly expect to find more fractures than in a wicker basket. . . . So far as my own experience has gone, I must

say that I have never seen any signs in the Japanese timber buildings which could be attributed to the effects of earthquakes, and His Excellency Yamao Yozo, Vice-Minister of Public Works, who has made the study of the buildings of Japan a speciality, told me that none of the temples and palaces, altho many of them are several centuries old, and altho they have been shaken by small earthquakes and also by many severe ones, show any signs of having suffered. The greatest damage wrought by large earthquakes appears to have resulted from the influx of large waves or from fires.—MILNE *Earthquakes*, ch. 7, p. 122. (A., 1899.)

959. EARTH-SCULPTURE OF PRIMITIVE MAN—*"Animal Mounds"—The "Alligator."*—The "Animal Mounds" which have been observed out of Wisconsin differ in many respects from the ordinary type. Near Granville, in Ohio, on a higher spur of land, is an earthwork, known in the neighborhood as the "Alligator." It has a head and body, four sprawling legs, and a curled tail. The total length is two hundred and fifty feet; the breadth of the body forty feet, and the length of the legs thirty-six feet. "The head, shoulders, and rump are more elevated than the other parts of the body, an attempt having evidently been made to preserve the proportions of the object copied." The average height is four feet, at the shoulders six.—AVEBURY *Prehistoric Times*, ch. 8, p. 256. (A., 1900.)

960. ECHOES OF THOUGHT—*After-images—Each Perception or Sensation Leaves Its Trace—Counting Strokes after Clock Has Struck.*—In the nervous system each stimulus leaves some latent activity behind it which only gradually passes away. Psychological proof of the same fact is afforded by those "after-images" which we perceive when a sensorial stimulus is gone. We may read off peculiarities in an after-image, left by an object on the eye, which we failed to note in the original. We may "hark back" and take in the meaning of a sound several seconds after it has ceased. Delay for a minute, however, and the echo itself of the clock or the question is mute; present sensations have banished it beyond recall. With the feeling of the present thing there must at all times mingle the fading echo of all those other things which the previous few seconds have supplied.—JAMES *Psychology*, vol. i, ch. 15, p. 634. (H. H. & Co., 1899.)

961. ECLIPSE OF THE SUN—*Beauty of the Spectacle—Colored Flames of the Chromosphere Shine Out when Disk is Darkened—Source of the "Unnatural Light."*—Those who were at leisure to watch the coming shadow of the moon described its curved outline as distinctly visible on the plains. "A rounded ball of darkness with an orange-yellow border," one called it. Those, again, who looked down on the bright clouds below sa, the shadow was preceded by a yellow fringe, casting a bright light over the clouds and passing into orange, pink, rose-red, and dark red, in about twenty seconds. This beautiful effect was noticed by nearly all the amateur observers present, who had their attention at liberty, and was generally unseen by the professional ones, who were shut up in dark tents with photometers, or engaged otherwise than in admiring the glory of the spectacle as a spectacle merely. This strange light, forming a band of color about the shadow as seen from above, must have really covered ten miles or more in width, and have occupied a considerable fraction of a minute in passing over the heads of those below, to whom it probably constituted that lurid light on their landscape I have spoken of as so peculiar and "unnatural." It seems to be due to the colored flames round the sun, which shine out when its brighter light is extinguished. —LANGLEY *New Astronomy*, ch. 2, p. 56. (H. M. & Co.)

962. ECLIPSE, TOTAL, OF THE SUN—*Once Prolific of Superstition—Still Weird and Awe-inspiring—Man's Conscious Dependence on the Orb of Day.*—Of all astronomical phenomena, there are few which have struck the human imagination so much as total eclipses of the sun. What spectacle more strange, in fact, than that of the sudden disappearance of the day-star at noonday in the midst of a clear sky? In the days when humanity was ignorant of the natural causes of these effects, such a disappearance was considered as supernatural, and they saw in it with terror a manifestation of the divine anger. Since the natural causes have been discovered, and these phenomena are seen to answer to our calculations with the most obedient fidelity, all supernatural terror has disappeared from cultivated minds, but the grand spectacle does not the less impress the beholder.

At the hour predicted by the astronomer we see the brilliant disk of the sun cut into towards the west, and a black segment slowly advancing, eating away the solar disk until it is reduced to the form of a thin luminous crescent. At the same time daylight diminishes; from all sides a wan and sinister gleam replaces the brilliant light in which Nature rejoiced, and an infinite sadness falls upon the world. Very soon there remains nothing of the radiant star but a narrow arc of light, and hope appears disposed to wing its flight from this earth, so long illuminated by the paternal sun. Life seems still connected with the sky by an invisible thread, when suddenly the last ray of daylight dies out, and a darkness as profound as it is sudden spreads all around us, reducing the whole of Nature to astonishment and silence. The stars shine in the sky! The man who would still speak and communicate his impressions while attentively watching the phenomenon cries out with surprise; then he becomes silent, struck with stupor. The singing-bird crouches un-

der the leaf; the dog takes refuge against the legs of his master; the hen covers the chickens with her wings. Living nature is hushed—dumb with astonishment. Night has come—a night sometimes intense and profound, but oftener incomplete, strange, and extraordinary, the earth remaining vaguely illuminated by a reddish light reflected from distant regions of the atmosphere situated outside the cone of the lunar shadow which produces the eclipse. Sometimes we see shining during the eclipse all the stars of the first and second magnitude which are above the horizon, sometimes only the brightest of the planets. The temperature of the air rapidly sinks several degrees.—FLAMMARION *Popular Astronomy,* bk. ii, ch. 9, p. 194. (A.)

963. ECLIPSES CALCULATED IN FAR ANTIQUITY—*Chinese Astronomers Punished for Neglect.*—Indeed, each of the great civilizations of the ancient world seems to have had its own system of astronomy strongly marked by the peculiar character of the people among whom it was found. Several events recorded in the annals of China show that the movements of the sun and the laws of eclipses were studied in that country at a very early age. Some of these events must be entirely mythical. . . . But there is another event which, even if we place it in the same category, must be regarded as indicating a considerable amount of astronomical knowledge among the ancient Chinese. We refer to the tragic fate of Hi and Ho, astronomers royal to one of the ancient emperors of that people. It was part of the duty of these men to carefully study the heavenly movements, and give timely warning of the approach of an eclipse or other remarkable phenomenon. But, neglecting this duty, they gave themselves up to drunkenness and riotous living. In consequence, an eclipse of the sun occurred without any notice being given; the religious rites due in such a case were not performed, and China was exposed to the anger of the gods. To appease their wrath, the unworthy astronomers were seized and summarily executed by royal command. Some historians have gone so far as to fix the date of this occurrence, which is variously placed at from 2128 to 2159 before the Christian era. If this is correct, it is the earliest of which profane history has left us any record.—NEWCOMB *Popular Astronomy,* pt. i, int., p. 2. (H., 1899.)

964. ECSTASY OF HEALTH—*Animals Share with Man.*—We see that the inferior animals, when the conditions of life are favorable, are subject to periodical fits of gladness, affecting them powerfully and standing in vivid contrast to their ordinary temper. And we know what this feeling is—this periodic intense elation which even civilized man occasionally experiences when in perfect health, more especially when young. There are moments when he is mad with joy, when he cannot keep still, when his impulse is to sing and shout aloud and laugh at nothing, to run and leap and exert himself in some extravagant way. Among the heavier mammalians the feeling is manifested in loud noises, bellowings, and screamings, and in lumbering, uncouth motions—throwing up of heels, pretended panics, and ponderous mock battles.—HUDSON *Naturalist in La Plata,* ch. 19, p. 280. (C. & H., 1895.)

965. EDIFICE NOT SEEN TILL SCAFFOLDING IS REMOVED—*Admission of German Scientist—Accumulation of Details Spoils Perspective.*—There is, perhaps, some truth in the accusation advanced against many German scientific works, that they lessen the value of general views by an accumulation of detail, and do not sufficiently distinguish between those great results which form, as it were, the beacon-lights of science, and the long series of means by which they have been attained. This method of treating scientific subjects led the most illustrious of our poets [Goethe] to exclaim with impatience, "The Germans have the art of making science inaccessible." An edifice cannot produce a striking effect until the scaffolding is removed, that had of necessity been used during its erection.—HUMBOLDT *Cosmos,* vol. i, int., p. 47. (H., 1897.)

966. EDIFICE OF A HIDDEN BUILDER—*Crystal Shaped According to Law—Form Determined by Polarity of Molecules.*—I wish you to realize intellectually the process of crystalline architecture. Look then into a granite quarry, and spend a few minutes in examining the rock. It is not of perfectly uniform texture. It is rather an agglomeration of pieces, which, on examination, present curiously defined forms. You have there what mineralogists call quartz, you have felspar, you have mica. In a mineralogical cabinet, where these substances are preserved separately, you will obtain some notion of their forms. You will see there, also, specimens of beryl, topaz, emerald, tourmalin, heavy spar, fluor-spar, Iceland spar—possibly a full-formed diamond. . . . These crystals, you will observe, are put together according to law; they are not chance productions; and, if you care to examine them more minutely, you will find their architecture capable of being to some extent revealed. They often split in certain directions before a knife-edge, exposing smooth and shining surfaces, which are called planes of cleavage; and by following these planes you sometimes reach an internal form, disguised beneath the external form of the crystal. Ponder these beautiful edifices of a hidden builder. You cannot help asking yourself how they were built; and familiar as you now are with the notion of a polar force, and the ability of that force to produce structural arrangement, your inevitable answer will be that those crystals are built by the play of polar forces with

which their molecules are endowed. In virtue of these forces, atom lays itself to atom in a perfectly definite way, the final visible form of the crystal depending upon this play of its molecules.—TYNDALL *Lectures on Light*, lect. 3, p. 101. (A., 1898.)

967. EDUCATION AND MAN—*Reaction on Impressions.*—Man is an organism for reacting on impressions: his mind is there to help determine his reactions, and the purpose of his education is to make them numerous and perfect. Our education means, in short, little more than a mass of possibilities of reaction, acquired at home, at school, or in the training of affairs.—JAMES *Talks to Teachers*, ch. 6, p. 38. (H. H. & Co., 1900.)

968. EDUCATION A TEST—*Capacity to Receive Differs with Race.*—In measuring the minds of the lower races, a good test is, how far their children are able to take a civilized education. The account generally given by European teachers who have had the children of lower races in their schools is that, tho these often learn as well as the white children up to about twelve years old, they then fall off, and are left behind by the children of the ruling race. This fits with what anatomy teaches of the less development of brain in the Australian and African than in the European. It agrees also with what the history of civilization teaches, that up to a certain point savages and barbarians are like what our ancestors were and our peasants still are, but from this common level the superior intellect of the progressive races has raised their nations to heights of culture. The white man, tho now dominant over the world, must remember that intellectual progress has been by no means the monopoly of his race. At the dawn of history the leaders of culture were the brown Egyptians, and the Babylonians, whose Accadian is not connected with the language of white nations, while the yellow Chinese, whose Tatar affinity is evident in their hair and features, have been for four thousand years or more a civilized and literary nation. The dark-whites, Assyrians, Phenicians, Persians, Greeks, Romans, did not start but carried on the forward movement of culture, while since then the fair-whites, as part of the population of France, Germany, and England, have taken their share not meanly, tho latest, in the world's progress.—TYLOR *Anthropology*, ch. 3, p. 74. (A., 1899.)

969. EDUCATION BASED ON ATTENTION — *Animals and Children — Idiots and Deaf-mutes.*—"The first and most important, but also the most difficult, task at the outset of an education is to overcome gradually the inattentive dispersion of mind which shows itself wherever the organic life preponderates over the intellectual. The training of animals . . . must be in the first instance based on the awakening of attention (*cf.* Aurian Leonard, 'Essai sur l'Education des Animaux,' Lille, 1842) that is to say, we must seek to make then gradually perceive separately things which if left to themselves, would not be attended to, because they would fuse with a great sum of other sensorial stimuli to a confused total impression, of which each separate item only darkens and interferes with the rest. Similarly at first with the human child. The enormous difficulty of deaf-mute- and especially of idiot-instruction is principally due to the slow and painful manner in which we succeed in bringing out from the general confusion of perception single items with sufficient sharpness." (Waitz, "Lehrbuch der Psychologie," p. 632.)—JAMES *Psychology*, vol. i, ch. 11, p. 405. (H. H. & Co. 1899.)

970. EDUCATION DEVELOPS MENTAL ENDOWMENT—*Genius Not the Result of Training.*—Fruits and vegetables must have good nurture to reach perfection, but the gardener knowns his labor will be vain unless he starts with seed which is adapted by nature for improvement by judicious nurture; and while it is hard for us to consider the question whether the arts and accomplishments of normal men are due to anything else than training and education we feel no such difficulty when the faculties of abnormal or exceptional individuals are in question; for the restriction of the powers of idiots is clearly correlated with deficient structure, and training and education are so obviously incompetent to account for the achievements of men of genius that we are apt to believe that their natural or innate powers are different in kind from anything in our own more commonplace selves. —BROOKS *Foundations of Zoology*, lect. 10, p. 261. (C. U. P., 1899.)

971. EDUCATION OF MAN FOR SPIRITUAL LIFE—*A Creative Purpose in Nature—Material Ends Not Supreme—Complexity of Light and Light-sensations.*—This question of absorption [of light], considered with reference to its molecular mechanism, is one of the most subtle and difficult in physics. We are not yet in a condition to grapple with it, but we shall be by and by. We have, in the first place, in solar light an agent of exceeding complexity, composed of innumerable constituents, refrangible in different degrees. We find, secondly, the atoms and molecules of bodies gifted with the power of sifting solar light in the most various ways, and producing by this sifting the colors observed in Nature and art. To do this they must possess a molecular structure commensurate in complexity with that of light itself. Thirdly, we have the human eye and brain, so organized as to be able to take in and distinguish the multitude of impressions thus generated. The light, therefore, at starting is complex; to sift and select it as they do, natural bodies must be complex; while to take in the impressions thus generated, the

human eye and brain, however we may simplify our conceptions of their action, must be highly complex. Whence this triple complexity? If what are called material purposes were the only end to be served, a much simpler mechanism would be sufficient; but instead of simplicity, we have prodigality of relation and adaptation—and this apparently for the sole purpose of enabling us to see things robed in the splendors of color. Would it not seem that Nature harbored the intention of educating us for other enjoyments than those derivable from meat and drink? At all events, whatever Nature meant—and it would be mere presumption to dogmatize as to what she meant—we find ourselves here, as the upshot of her operations, endowed with capacities to enjoy not only the materially useful, but endowed with others of indefinite scope and application, which deal alone with the beautiful and the true.—TYNDALL *Lectures on Light*, lect. 1, p. 39. (A., 1898.)

972. EDUCATION, VALUE OF NATURE-STUDY IN — *Faculty of Observation Trained Early in Childhood.*—I do not hesitate to affirm that a boy or girl of, say, ten years of age may receive a certain amount of elementary biological instruction, which will be of the greatest service in the training of the child's mind, and which will assist the due appreciation of its other studies. As Sir James Paget well remarks, "The askings of children seem to indicate a natural desire after a knowledge of the purposes fulfilled in Nature"; and even where this desire is most feebly developed, the plain, interesting teaching of the grand yet simple facts of biology will tend to arouse the latent curiosity of the child, and to early awaken its sympathies with the things of living Nature. Dr. Carpenter, in his evidence before the English Public Schools Commission, lays great stress upon the importance of enabling children to begin the study of physical and natural science at an early age. He says: "The training of the observing faculties by attention to the phenomena of Nature, both in physical and in natural science, seems to me to be the natural application of time at the age of, say, from eight to twelve." Dr. Carpenter further exemplifies, by citing his own case, the value of an early training in science as tending to cultivate the observant habits more thoroughly than when the study is entered upon at a later period. The evidence of the late Sir Charles Lyell goes to support Dr. Carpenter's views in relation to the advantages of training the observant faculties in early youth; the age of nine or ten, the late distinguished geologist maintained, being that at which the powers of observation are sufficiently developed, and when, if pupils be taught natural science, "they learn a vast deal of other things in consequence."—ANDREW WILSON *Biology in Education*, p. 16. (Hum., 1888.)

973. EFFECT BEYOND APPARENT CAUSE—*Change Produced by Rise in Temperature of Two Degrees—Arctic Desolation Succeeded by Life and Movement—One Step above Brute Intelligence Gives Human Intellect.*—In part of the arctic regions at this moment there is no such thing as liquid. Matter is only known there in the solid form. The temperature may be thirty-one degrees below zero or thirty-one degrees above zero without making the slightest difference; there can be nothing there but ice, glacier, and those crystals of ice which we call snow. But suppose the temperature rose two degrees, the difference would be indescribable. While no change for sixty degrees below that point made the least difference, the almost inappreciable addition of two degrees changes the country into a world of water. The glaciers, under the new conditions, retreat into the mountains, the vesture of ice drops into the sea, a garment of greenness clothes the land. So, in the animal world, a very small rise beyond the animal maximum may open the door for a revolution.—DRUMMOND *Ascent of Man*, ch. 5, p. 186. (J. P., 1900.)

974. ——— ——— *General Tide-movement Increased by Local Conditions.*—The moon raises the surface of the sea at the equator by fifty centimeters [about 19.7 inches], and, the action of the sun being added, the elevation reaches 74 centimeters [29.1 inches]. The height decreases up to the poles, where the amplitude of the oscillations is reduced to zero, and there is no tide, even when the sea is not frozen.

The amount by which the surface of the sea is raised and lowered successively is, in general, very much greater than what we have stated, assuming that this surface takes at each instant the figure of equilibrium which agrees with the magnitude and direction of the attractions of the sun and moon. We have seen that the greatest difference of level which can exist, on this hypothesis, between high water and the following low water is only 2.43 feet at the equator, if the sun and moon are at their mean distances. Now, there exist certain localities where the same difference exceeds thirty-two feet in the vertical direction.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 7, p. 166. (A.)

975. ——— ——— *Tides Rise Higher than Attraction of Sun and Moon Would Draw Them—Momentum Outlives Incitement.*—The waters of the sea, contained in a space limited on both sides by the continents, oscillate in this space, which forms a sort of vessel of small depth relatively to its surface: these oscillations are kept up by the disturbing actions of the moon and sun, of which the intensity and the direction change every instant. When, in consequence of these actions, the surface of the sea is forced to rise at a certain side of the basin which contains it, the water is carried to

that side, and the velocity with which the change of place is effected is the reason that it does not stop when the surface has attained equilibrium, but continues to move in the same direction until the velocity is completely destroyed by the action of gravity, and by the friction against the bottom; so that the oscillatory movement in the vertical direction thus becomes, on the borders of the sea, of much greater proportions than if the sea were placed at each instant in equilibrium under the action of the forces which are applied to it. We understand from this, not only why the sea is raised and lowered much more than seems to be caused by the actions of the moon and sun, but, further, why . . . the waters which have risen by these actions . . . continue still to rise for some time [afterwards] in virtue of their acquired velocity. —FLAMMARION *Popular Astronomy*, bk. ii, ch. 8, p. 167. (A.)

976. ——— *Unlocking of Energy —Spark Produces Conflagration.* — To account for the propagation of fire was one of the difficulties of the last century. A spark was found sufficient to initiate a conflagration. The effect here seemed beyond all proportion greater than the cause, and herein lay the philosophical difficulty. By a striking analogy Boscovich made clear to his own mind how small causes produce vast effects. He pictures a high mountain rising out of the sea, with sides so steep that blocks of stone are just able to rest upon them without rolling down. He supposes such blocks, diminishing gradually in size, to be strewn over the mountain—large below, moderate at the middle height, and dwindling to sand-grains at the top. A small bird touches with its foot a grain on the summit; it moves, sets the next large grains in motion, these again let loose the pebbles, these the larger stones, these the blocks; until finally the whole mountainside rolls violently into the sea, there producing mighty waves. Here the foot of the little bird unlocked the energy, the rest of the work being done by gravitation. This he regarded as an image whereby the propagation of fire might be rendered intelligible. The spark acts like the foot of the bird; it starts a process which is continued and vastly augmented by the molecular forces of the fuel. The force which moves a train is potential in the boiler before the steam is turned on. The hand of the engineer releases a detent and permits the potential to become actual. It, however, like the bird of Boscovich, only liberates a preexisting power. The action of the nerves in unlocking the power of the muscles also falls in admirably with the conception of Boscovich here described. —TYNDALL *Heat a Mode of Motion*, lect. 3, p. 64. (A., 1900.)

977. EFFECT, MIGHTY, FROM TRIVIAL CAUSE - *Time Multiplies Results—Natural Causes Extended through Limitless Past.*—Many geologists had previously imagined that the highest chains of mountains which rise on the surface of the earth could owe their origin only to enormous revolutions transforming a great part of the earth's surface, especially to colossal volcanic eruptions. Such chains of mountains as those of the Alps or the Cordilleras were believed to have arisen direct from the fiery fluid of the interior of the earth, through an enormous chasm in the broken crust. Lyell, on the other hand, showed that we can explain the formation of such enormous chains of mountains quite naturally by the same slow and imperceptible risings and depressions of the earth's surface which are still continually taking place, and the causes of which are by no means miraculous. Altho these depressions and risings may perhaps amount only to a few inches, or at most a few feet, in the course of a century, still in the course of some millions of years they are perfectly sufficient to raise up the highest chains of mountains, without the aid of mysterious and incomprehensible revolutions. In like manner, the meteorological action of the atmosphere, the influence of rain and snow, and, lastly, the breakers on the coasts, which by themselves seem to produce an insignificant effect, must cause the greatest changes if we only allow sufficiently long periods for their action. The multiplication of the smallest causes produces the greatest effects. Drops of water produce a cavity in a rock.—HAECKEL *History of Creation*, vol. i, ch. 6, p. 130. (K. P. & Co., 1899.)

978. EFFECT OF FIRE ON ANIMALS —*Birds Dashing Themselves against Lighthouse.*—The fires which travelers make for their protection actually serve to attract the beasts of prey, but the confusion and fear caused by the bright glare make it safe for the traveler to lie down and sleep in the light. Mammals do not lose their heads altogether, because they are walking on firm ground where muscular exertion and an exercise of judgment are necessary at every step; whereas birds floating buoyantly and with little effort through the air are quickly bewildered. Incredible numbers of migratory birds kill themselves by dashing against the windows of lighthouses; on bright moonlight nights the voyagers are comparatively safe; but during dark cloudy weather the slaughter is very great; over six hundred birds were killed by striking a lighthouse in Central America in a single night. On insects the effect is the same as on the higher animals: on the ground they are attracted by the light, but keep, like wolves and tigers, at a safe distance from it; when rushing through the air and unable to keep their eyes from it they fly into it, or else revolve about it, until, coming too close, their wings are singed.—HUDSON *Naturalist in La Plata*, ch. 13, p. 176. (C. & H., 1895.)

979. EFFECT OF HEAT AND COLD RESISTLESS—*Lead Crawls Down Cathedral Roof.*—A very curious effect of expansion was observed, and explained, some years ago, by the late Canon Moseley. The choir of Bristol Cathedral was covered with sheet lead, the length of the covering being 60 feet, and its depth 19 feet 4 inches. It had been laid on in the year 1851, and two years afterwards it had moved bodily down through a distance of eighteen inches. The descent had been continually going on from the time the lead had been laid down, and an attempt made to stop it by driving nails into the rafters had failed; for the force of descent was sufficient to draw out the nails. The roof was not a steep one, and the lead would have rested on it forever, without sliding. What, then, was the cause of the descent? Simply this: The lead was exposed to the varying temperatures of day and night. During the day the heat imparted to it caused it to expand. Had it lain upon a horizontal surface, it would have expanded equally all round; but as it lay upon an inclined surface, it expanded more freely downwards than upwards. When, on the contrary, the lead contracted at night, its upper edge was drawn more easily downwards than its lower edge upwards. Its motion was therefore that of a common earthworm; it pushed its lower edge forward during the day, and drew its upper edge after it during the night, and thus by degrees it crawled through a space of eighteen inches in two years. Every minor change of temperature during the day and during the night contributed also to the result; indeed Canon Moseley afterwards found the main effect to be due to these quicker alternations of temperature.—TYNDALL *Heat a Mode of Motion*, lect. 4, p. 95. (A., 1900.)

980. EFFECT OF HUMAN INFANCY AND CHILDHOOD—*Animal Affection for Offspring Perishes and Is Forgotten.*—Till the brain arrived, everything was too brief, too rapid for ethical achievements; animals were in a hurry to be born, children thirsted to be free. There was no helplessness to pity, no pain to relieve, no quiet hours, no watching; to the mother, no moment of suspense—the most educative moment of all—when the spark of life in her little one burned low. Parents could be [of] no use to their offspring physically, and the offspring could be [of] no use to their parents psychically. The young required no infancy; the old acquired no sympathy. Even among the other mammalia or the birds the mother's chance was small. There, infancy extends to a few days or weeks, yet is but an incident in a life preoccupied with sterner tasks. A lioness will bleed for her cub to-day, and in to-morrow's struggle for life contend with it to the death. A sheep knows its lamb only while it is a lamb. The affection in these cases, fierce enough while it lasts, is soon forgotten, and the traces it left in the brain are obliterated before they have furrowed into habit.—DRUMMOND *Ascent of Man*, ch. 8, p. 287. (J. P., 1900.)

981. EGG PRODUCING ALL MATERIAL FOR THE CHICKEN—The egg itself contains all the materials of a complete animal. Bones, muscles, viscera, brain, nerves, and feathers of the chicken—all are produced from the egg, nothing being added, and little or nothing taken away.

I should, however, add that in eating an egg we do not get quite so much of it as the chicken does. Liebig found by analysis that in the white and the yolk there is a deficiency of mineral matter for supplying the bones of the chick, and that this deficiency is supplied by some of the shell being dissolved by the phosphoric acid which is formed inside the egg by the combination of the oxygen of the air (which passes through the shell) with the phosphorus contained in the soft matter of the egg.

By comparing the shell of a hen's egg after the chicken is hatched from it with that of a freshly laid egg, the difference of thickness may be easily seen.—WILLIAMS *Chemistry of Cookery*, ch. 3, p. 19. (A., 1900.)

982. EGOISM, UNMITIGATED, OF ANCIENT GEOLOGIC WORLD—*"Dragons of the Prime"—Slow Attainment of Better Things.*—What spectacle could be more dreary than that of the Jurassic period, with its lords of creation, the oviparous dinosaurs, crawling or bounding over the land, splashing amid the mighty waters, whizzing bat-like through the air, horrible brutes innumerable, with bulky bodies and tiny brains, clumsy, coarse in fiber, and cold-blooded.

"Dragons of the prime,
That tare each other in their slime."

The remnants of that far-off dismal age have been left behind in great abundance, and from them we can easily reconstruct the loathsome picture of a world of dominating egoism. Nearly nine-tenths of our planet's past life-history, measured in duration, had passed away without achieving any higher result than this—a fact which for impatient reformers may have in it some crums of consolation.—FISKE *Through Nature to God*, pt. ii, ch. 11, p. 122. (H. M. & Co., 1900.)

983. EGYPT, SEEDS AND PLANTS OF—*Superstition Ministers to Science.*—The evidence derived from the Egyptian monuments was not confined to the animal kingdom; the fruits, seeds, and other portions of twenty different plants, were faithfully preserved in the same manner; and among these the common wheat was procured by Delille, from closed vessels in the sepulchers of the kings, the grains of which retained not only their form, but even their color; so effectual has proved the process of embalming with bitumen in a dry and equable climate.

No difference could be detected between this wheat and that which now grows in the East and elsewhere; and in regard to the barley, I am informed by Mr. Brown, the celebrated botanist, that its identity with the grain of our own times can be tested by the closest comparison. On examining, for example, one of the seeds from Mr. Sam's Egyptian collection in the British Museum, it is found that "the structure of the husks, or that part of the flower which is persistent, agrees precisely with the barley of the present day, in having one perfect flower and the filiform rudiments of a second." Some naturalists believe that the perfect identification of the ancient Egyptian cerealia with the varieties now cultivated has been carried still further by sowing the seeds taken out of the catacombs, and raising plants from them; but we want more evidence of this fact. Certain it is, that when the experiment was recently made in the botanic garden at Kew, with 100 seeds of wheat, barley, and lentils, from the Egyptian collection before mentioned of the British Museum, not one of them would germinate.—LYELL *Principles of Geology*, bk. iii, ch. 34, p. 587. (A., 1854.)

984. ——— ——— *Travelers Imposed Upon—Evidence Not Carefully Sifted.*—I by no means wish to express an opinion that seeds cannot retain their vitality after an entombment of 3,000 years; but one of my botanical friends who entertained a philosophical doubt on this subject, being desirous of ascertaining the truth of three or four alleged instances of the germination of "mummy wheat," discovered, on communicating with several Egyptian travelers, that they had produced the grains in question, not directly from the catacombs, but from the Arabs, who are always ready to supply strangers with an article now very frequently in demand. The presence of an occasional grain of Indian corn or maize in several of the parcels of grain shown to my friend as coming from the catacombs confirmed his skepticism.—LYELL *Principles of Geology*, bk. iii, ch. 34, p. 587. (A., 1854.)

985. ELECTRICITY A FORM OF ENERGY—*Electric "Fluid" and "Current" Misnomers.*—Electricity is not a fluid, or any form of material substance, but a form of energy. Energy is expressed in different ways, and, while as energy it is one and the same, we call it by different names—as heat energy, chemical energy, electrical energy, and so on. They will all do work, and in that respect are alike. One difficulty in explaining electrical phenomena is the nomenclature that the science is loaded down with. All the old names were adopted when electricity was regarded as a fluid, hence the word "current." It is spoken of as "flowing" when it does not flow any more than light flows.—ELISHA GRAY *Nature's Miracles*, vol. iii, ch. 5, p. 41. (F. H. & H., 1900.)

986. ELECTRICITY A RECENT SCIENCE—Electricity as a well-developed science is not old. Those of us who have lived fifty years have seen nearly all its development so far as it has been applied to useful purposes, and those who have lived over twenty-five years have seen the major portion of its development.—ELISHA GRAY *Nature's Miracles*, vol. iii, ch. 2, p. 6. (F. H. & H., 1900.)

987. ELECTRICITY A RESULT OF EVERY CHANGE—*Perhaps a Mode of Molecular Motion.*—More recently it has been discovered that friction is by no means the only source of electricity, and it seems probable that no change, either chemical or physical, takes place in Nature without some manifestation of this agent. It was at first supposed that there were several kinds of electricity, which were named thermo-electricity, magneto-electricity, voltaic electricity, and animal electricity, according to the nature of the process in which the electrical action was developed; but it is now universally conceded that all are only different manifestations of the same agent, and most investigators believe that electricity will in time be shown to be a form of molecular motion analogous to that which produces the phenomena of light and heat, altho it has not as yet been found possible to frame a comprehensive and intelligible theory based upon this hypothesis.—COOKE *Religion and Chemistry*, ch. 2, p. 59. (A., 1897.)

988. ELECTRICITY, EVOLUTION OF, FROM STEAM—*Theory of the Thunder-cloud.*—If the vaporization of the water were shown to be the source of the electricity, Professor Henry thought the phenomena might be readily explained by the beautiful theory of Becquerel, in regard to the production of the great intensity of the electricity in the thunder-cloud. According to this theory, each particle of the vapor carries up with it into the atmosphere the free electricity which it receives at the moment of the change of state: this being diffused through the whole capacity of the air is of very feeble intensity, altho of great quantity; but the condensation of the vapor in a cloud affords a continuous conductor, and consequently the electricity of all the particles of the interior, according to the well-known principles of distribution, rushes to the surface of the cloud, and hence the great intensity of the lightning. Agreeably with this hypothesis, the insulated conductor, placed in the steam, would act not only as a collector, but also as a condenser of the free but feeble electricity of the vapor.—HENRY *Scientific Writings*, p. 190. (Sm. Inst., 1840.)

989. ELECTRICITY GENERATED BY VOLCANIC ERUPTION—*Elemental Forces Joined.*—It is well known that when high-pressure steam is allowed to escape through an orifice, electricity is abundantly gener-

ated by the friction, and Sir William Armstrong's hydro-electric machine is constructed on this principle. Every volcano in violent eruption is a very efficient hydro-electric machine, and the up-rushing column is in a condition of intense electrical excitation. This result is probably aided by the friction of the solid particles as they are propelled upwards and fall back into the crater. The restoration of the condition of electrical stability between this column and the surrounding atmosphere is attended with the production of frequent lightning-flashes and thunderclaps, the sound of the latter being usually, however, drowned in the still louder roar of the up-rushing steam-column.—JUDD *Volcanoes*, ch. 2, p. 29. (A., 1899.)

990. ELECTRICITY GIVES NEW PRODUCTS—*Carborundum.*—The production of electricity in such enormous quantities as are generated at Niagara Falls has led to many discoveries and will lead to many more. Products that at one time existed only in the chemical laboratory for experimental purposes have been so cheapened by utilizing electrical energy in their manufacture as to bring them into the play of every-day life. Still other products have only been discovered since the advent of heavy electrical currents. A substance called carborundum, which was discovered as late as 1891, has now become the basis of an industry of no small importance. It is a substance not unlike a diamond in hardness, and not very unlike it in its composition. The chief use to which it is put is for grinding metals and all sorts of abrasive work. It is manufactured into wheels, in structure like the emery-wheel, and serves the same purpose. It is much more expensive than the emery-wheel, but it is claimed that it will do enough more and better work to make it fully as economical.—ELISHA GRAY *Nature's Miracles*, vol. iii, ch. 25, p. 209. (F. H. & H., 1900.)

991. ELECTRICITY IN ANIMALS—*Battery of the Electric Ray—Scientific Structure in Living Organism.*—The electric ray, or torpedo, has been provided with a battery closely resembling, but greatly exceeding in the beauty and compactness of its structure, the batteries whereby man has now learned to make the laws of electricity subservient to his will. There are no less than 940 hexagonal columns in this battery like those of a bee's comb, and each of these is subdivided by a series of horizontal plates, which appear to be analogous to the plates of the voltaic pile. The whole is supplied with an enormous amount of nervous matter, four great branches of which are as large as the animal's spinal cord, and these spread out in a multitude of threadlike filaments round the prismatic columns, and finally pass into all the cells. This, again, seems to suggest an analogy with the arrangement by which an electric current, passing through a coil and round a magnet, is used to intensify the magnetic force. A complete knowledge of all the mysteries which have been gradually unfolded from the days of Galvani to those of Faraday, and of many others which are still inscrutable to us, is exhibited in this structure.—ARGYLL *Reign of Law*, ch. 2, p. 61. (Burt.)

992. ELECTRICITY IN MEDICINE—*Electric Lamps for Pathological Investigation—Dentistry Aided—Submarine Boats.*—Small incandescent lamps are now used for examinations of the larynx and in dentistry, and a lamp has even been introduced into the stomach by which the condition of that organ can be examined. For this last purpose numerous ingenious arrangements have to be made to prevent possible injury, and by means of prisms at the bends of the tube the operator can inspect the interior of the organ under a brilliant light. Other internal organs have been explored in a similar manner, and many new applications in this direction will no doubt be made. In illuminating submarine boats and exploring the interiors of sunken vessels it does what could hardly be effected by any other means. —WALLACE *The Wonderful Century*, ch. 4, p. 29. (D. M. & Co., 1899.)

993. ELEMENTS, CHEMICAL, MAY BE COMPOUNDS—*Perhaps Resolvable on the Sun and Stars—The "Dissociation Theory."*—Professor Lockyer's view [of the separation or dissociation of chemical elements on the sun] has the argument from continuity in its favor. It only asks us to believe that processes which we know to take place on the earth under certain conditions, are carried further in the sun, where the same conditions are, it may be presumed, vastly exalted. We find that the bodies we call "compound" split asunder at fixed degrees of heat within the range of our resources. Why should we hesitate to admit that the bodies we call "simple" do likewise at degrees of heat without the range of our resources? The term "element" simply expresses terrestrial incapability of reduction. That, in celestial laboratories, the means and their effect here absent should be present, would be an inference challenging, in itself, no expression of incredulity.

Yet it is, in point of fact, a revolutionary one, and its acceptance will involve the reconstruction of more than one fair edifice of scientific thought.—CLERKE *History of Astronomy*, pt. ii, ch. 4, p. 259. (Bl., 1893.)

994. ELEMENTS IN OTHER SUNS—*Spectrum of Sirius.*—The spectrum of this brilliant white star [Sirius] is very intense; but seen at its small altitude above the horizon, even when it is most favorably situated, the observation of the finest lines is rendered very difficult by the motions of the atmosphere. Three, if not four, elementary bodies show spectra in which the lines coincide

with those of Sirius; these are sodium, magnesium, hydrogen, and probably iron. The lines of hydrogen are abnormally strong compared to those which exist in the solar spectrum.—FLAMMARION *Popular Astronomy,* bk. vi, ch. 6, p. 609. (A.)

995. ELEMENTS OF EARTHLY SUBSTANCE FOUND WIDELY DIFFUSED IN SPACE—*Still Surrounded by the Unknown.*—We cannot, indeed, say that we have explained all spectra; many fixed stars exhibit peculiarly banded spectra, probably belonging to gases whose molecules have not been completely resolved into their atoms by the high temperature. In the spectrum of the sun, also, are many lines which we cannot identify with those of terrestrial elements. It is possible that they may be due to substances unknown to us; it is also possible that they are produced by the excessively high temperature of the sun, far transcending anything we can produce. But this is certain, that the known terrestrial substances are widely diffused in space.—HELMHOLTZ *Popular Lectures,* lect. 4, p. 156. (L. G. & Co., 1898.)

996. ELEMENTS OF TERROR ACCUMULATED—*Lightnings Attend Volcanic Eruption.*—Another striking phenomenon which was exhibited in the great eruption of Vesuvius in 1872 was the vivid display of lightning accompanied by thunder. The uprushing current of steam and rock-fragments forms a vertical column, but as the steam condenses it spreads out into a great horizontal cloud which is seen to be made up of the great globes of vapor emitted at successive explosions. When there is little or no wind the vertical column with a horizontal cloud above it bears a striking resemblance to the stone-pine trees which form so conspicuous a feature in every Neapolitan landscape. Around this column of vapor the most vivid lightning constantly plays and adds not a little to the grand and awful character of the spectacle of a volcanic eruption, especially when it is viewed by night.—JUDD *Volcanoes,* ch. 2, p. 28. (A., 1899.)

997. ELEVATION OF BED OF NILE—*Fertility Encroaching upon the Desert.*—The bed of the Nile always keeps pace with the general elevation of the soil, and the banks of this river, like those of the Mississippi and its tributaries, are much higher than the flat land at a distance, so that they are seldom covered during the highest inundations. In consequence of the gradual rise of the river's bed, the annual flood is constantly spreading over a wider area, and the alluvial soil encroaches on the desert, covering, to the depth of six or seven feet, the base of statues and temples which the waters never reached 3,000 years ago. Altho the sands of the Libyan Desert have in some places been drifted into the valley of the Nile, yet these aggressions, says Wilkinson, are far more than counterbalanced by the fertilizing effect of the water which now reaches farther inland towards the desert, so that the number of square miles of arable soil is greater at present than at any previous period.—LYELL *Principles of Geology,* bk. ii, ch. 17, p. 262. (A., 1854.)

998. ELEVATION, SLOW, OF EARTH'S CRUST—*Streams Cut Down as Fast as Surface Is Lifted.*—Yet, strange to say, none of these earth-movements succeeded in deflecting the main drainage of the [Grand Cañon] district. The Colorado and its chief affluents continued to flow in the courses they had attained at the final disappearance of the great lake. It is clear, therefore, that the bending and dislocation of the strata must have proceeded very slowly, for the rivers were able to cut their way across both flexures and faults as fast as these showed at the surface.—GEIKIE *Earth Sculpture,* ch. 3, p. 57. (G. P. P., 1898.)

999. EMBLEM OF DIVINE FULNESS—*Power of the Sun's Heat—Lavish Beneficence.*—Working out the results of the Mount Whitney expedition, he [Langley] was led to conclude atmospheric absorption to be fully twice as effective as had hitherto been supposed. Scarcely sixty per cent., in fact, of those solar radiations which strike perpendicularly through a seemingly translucent sky attain the sea-level. The rest are reflected, dispersed, or absorbed. This discovery involved a large addition to the original supply so mercilessly cut down in transmission. . . . The sun's heat reaching the outskirts of our atmosphere is capable of doing without cessation the work of an engine of three horse-power for each square yard of the earth's surface. Thus, modern inquiries, tho they give no signs of agreement, within any tolerable limits of error, as to the probable temperature of the sun, tend, with growing certainty, to render more and more evident the vastness of the thermal stores contained in the great central reservoir of our system.—CLERKE *History of Astronomy,* pt. ii, ch. 5, p. 279. (Bl., 1893.)

1000. EMBRYO SHAPED BY VIEWLESS ARTIST—The student of Nature wonders the more and is astonished the less, the more conversant he becomes with her operations; but of all the perennial miracles she offers to his inspection, perhaps the most worthy of admiration is the development of a plant or of an animal from its embryo. Examine the recently laid egg of some common animal, such as a salamander or a newt. It is a minute spheroid in which the best microscope will reveal nothing but a structureless sac, enclosing a glairy fluid, holding granules in suspension. But strange possibilities lie dormant in that semi-fluid globule. Let a moderate supply of warmth reach its watery cradle, and the plastic matter undergoes changes so rapid and yet so steady and purpose-like in their succession, that one can only compare them to those operated by a skilled modeler upon a form-

less lump of clay. As with an invisible trowel, the mass is divided and subdivided into smaller and smaller portions, until it is reduced to an aggregation of granules not too large to build withal the finest fabrics of the nascent organism. And then it is as if a delicate finger traced out the line to be occupied by the spinal column, and molded the contour of the body; pinching up the head at one end, the tail at the other, and fashioning flank and limb into due salamandrine proportions, in so artistic a way that, after watching the process hour by hour, one is almost involuntarily possessed by the notion that some more subtle aid to vision than an achromatic would show the hidden artist, with his plan before him, striving with skilful manipulation to perfect his work.—HUXLEY *Lay Sermons*, serm. 12, p. 260. (G. P. P., 1899.)

1001. EMOTION AND PASSION, DEVELOPMENT DEPENDENT ON—*Mission of Pain.*—But human life and human development, in the wider and higher meaning of those words, would be infinitely less rich and interesting were it not for so varied and mighty emotions and passions, with all the part they have played in history, art, and religion. In a grander significance than biology or comparative psychology can properly recognize, the effective forces have been "serviceable" to the race. If the final purpose of life were merely to conserve and propagate itself, there would seem to be as little use for so many and strong emotions as for so much and such qualitatively varied pain. At this point, psychology is compelled to hand over to ethical philosophy rather than to biology the larger problems started by the study of human feeling. Here we find, on one side, the conclusion expressed by Matthew Arnold, as follows:

"Fulness of life and power of feeling, ye
Are for the happy, for the souls at ease,
Who dwell on a firm basis of content."

But, on the other side, the rational faith of Browning:

"Put pain from out the world, what room were left
For thanks to God, for love to man?"

—LADD *Psychology*, ch. 23, p. 558. (S., 1899.)

1002. EMOTION, FIELD FOR STUDY OF—*Best Observed among the Common People.*—In order to analyze the involuntary movements occasioned by pain, joy, fear, anger, and other emotions, Leonardo da Vinci counseled young artists to mingle with the common people, where the various stirrings of the heart are naturally imprinted in change of countenance and of gesture.—KAAT *Leonardo da Vinci als Naturforscher.* (Translated for *Scientific Side-Lights.*)

1003 EMULATION HAS A NOBLE SIDE—*Rivalry Leads to Magnanimity.*—The feeling of rivalry lies at the very basis of our being, all social improvement being largely due to it. There is a noble and generous kind of rivalry, as well as a spiteful and greedy kind; and the noble and generous form is particularly common in childhood. All games owe the zest which they bring with them to the fact that they are rooted in the emulous passion, yet they are the chief means of training in fairness and magnanimity.—JAMES *Talks to Teachers*, ch. 7, p. 52. (H. H. & Co., 1900.)

1004. ENDOWMENT CONDITIONS EXPERIENCE—*Child Learning to Walk—Chimpanzee—Dancing Dog.*—It must be clear to any one who compares the erect progression of a child who has just learned to walk with that of a "dancing dog," or even of a chimpanzee, that while experience makes its acquirement possible in each case, only an organism which is at the same time structurally adapted for erect progression, and possessed of a special coordinating faculty, can turn such experience to full account.—CARPENTER *Mental Physiology*, bk. ii, ch. 11, p. 474. (A., 1900.)

1005. ENDS AND MEANS IN SCIENCE—*Each Achievement a Step to New Discovery.*—The growth of science is organic. That which to-day is an end becomes to-morrow a means to a remoter end. Every new discovery in science is immediately made the basis of other discoveries, or of new methods of investigation. Thus about fifty years ago, Oersted, of Copenhagen, discovered the deflection of a magnetic needle by an electric current; and about the same time Thomas Seebeck, of Berlin, discovered thermo-electricity. These great discoveries were soon afterwards turned to account by Nobili and Melloni in the construction of an instrument which has vastly augmented our knowledge of radiant heat.—TYNDALL *Lectures on Light*, lect. 5, p. 179. (A., 1898.)

1006. ——— ——— *Magnetic Attraction vs. Human—Man Changes Means to Reach Determined End.*—If some iron filings be sprinkled on a table and a magnet brought near them, they will fly through the air for a certain distance and stick to its surface. A savage seeing the phenomenon explains it as the result of an attraction or love between the magnet and the filings. But let a card cover the poles of the magnet, and the filings will press forever against its surface without its ever occurring to them to pass around its sides and thus come into more direct contact with the object of their love. . . . If now we pass from such actions as these to those of living things, we notice a striking difference. Romeo wants Juliet as the filings want the magnet: and if no obstacles intervene he moves towards her by as straight a line as they. But Romeo and Juliet, if a wall be built between them, do not remain idiotically pressing their faces against its opposite sides like the magnet and the filings with the card. Romeo soon finds a circuitous way, by

scaling the wall or otherwise, of touching Juliet's lips directly. With the filings the path is fixed; whether it reaches the end depends on accidents. With the lover it is the end which is fixed, the path may be modified indefinitely.—JAMES *Psychology*, vol. i, ch. 1, p. 6. (H. H. & Co., 1899.)

1007. ENDURANCE A GROWTH—*Ability to Sustain Pressure Gradually Acquired—Deep-sea Organisms Perish from Lack of Pressure at Surface.*—It is but reasonable to suppose that the ability to sustain this enormous pressure [of the ocean depths] can only be acquired by animals after generations of gradual migrations from shallow waters. Those forms that are brought up by the dredge from the depths of the ocean are usually killed and distorted by the enormous and rapid diminution of pressure in their journey to the surface, and it is extremely probable that shallow-water forms would be similarly killed and crushed out of shape were they suddenly plunged into very deep water.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 21. (A., 1894.)

1008. ENDURANCE OF HIGH TEMPERATURES BY HUMAN BODY—*Heat Converted into Work.*—You would certainly suffer if you lay down upon a plate of metal in a Turkish bath; but you do not suffer when you lie down on a bench of wood. By preserving the body from contact with good conductors, very high temperatures may be endured. Eggs may be boiled, and beefsteaks cooked, by the heat of an apartment, in which the bodies of living men sustain no injury. The philosophy of this last experiment is worthy of a moment's consideration. With it the names of Blagden and Chantrey are associated, those eminent men having exposed themselves in ovens to temperatures considerably higher than that of boiling water. Let us compare the condition of the two living human beings with that of two marble statues, placed in the same oven. The statues become gradually hotter, until finally they assume the temperature of the air of the oven; the two men, under the same circumstances, do not similarly rise in temperature. If they did, the tissues of the body would be infallibly destroyed, the temperature endured being more than sufficient to stew the muscles in their own liquids. Here the excess of heat, instead of being applied to increase the temperature of the body, is applied to change its aggregation; the heat prepares the perspiration, forces it through the pores, and vaporizes it. Heat is thus consumed in work. This is the waste-pipe, if I may use the term, through which the excess overflows. Some people have professed to see, in this power of the living body to resist a high temperature, a conservative action peculiar to the vital force. No doubt all the actions of the animal organism are connected with what we call its vitality; but the action here referred to is the same in kind as the melting of ice or the vaporization of water. It consists simply in the diversion of heat from the purposes of temperature to the performance of work.—TYNDALL *Heat a Mode of Motion*, lect. 9, p. 242. (A., 1900.)

1009. ENEMIES ESCAPED BY MIGRATION—*Plants Thrive in New Soil.*—Every horticulturist knows that apples grown in a new country, that is suited to them, are healthy and fair; but, sooner or later, the scab, and codling-moth, and bitter rot, and bark-louse arrive, each to begin its particular mode of attack. Peach-trees in new places, remote from others, are often easily grown and free from dangers; but soon will arrive the yellows, borers, leaf-curl rot, and other enemies. For a few years plums may be grown, in certain new localities, without danger from curculio, or rot, or shot-hole fungus. It has long been known that the nicest way to grow a few cabbages, radishes, squashes, cucumbers, or potatoes, is to plant a few here and there in good soil, at considerable distances from where any have heretofore been grown. For a time enemies are not likely to find them. —BEAL *Seed Dispersal*, ch. 9, p. 85. (G. & Co., 1898.)

1010. ENERGY AMID INHIBITIONS THE HIGHEST MENTAL TYPE—Not to proceed immediately to extremities, to be still able to act energetically under an array of inhibitions—that indeed is rare and difficult. Cavour, when urged to proclaim martial law in 1859, refused to do so, saying: "Any one can govern in that way. I will be constitutional." Your parliamentary rulers, your Lincoln, your Gladstone, are the strongest type of man, because they accomplish results under the most intricate possible conditions. We think of Napoleon Bonaparte as a colossal monster of willpower, and truly enough he was so. But, from the point of view of the psychological machinery, it would be hard to say whether he or Gladstone was the larger volitional quantity; for Napoleon disregarded all the usual inhibitions, and Gladstone, passionate as he was, scrupulously considered them in his statesmanship.—JAMES *Talks to Teachers*, ch. 15, p. 180. (H. H. & Co., 1900.)

1011. ENERGY AND FORCE DISCRIMINATED—*Work the Measure of Energy.* —To the ordinary mind energy and force represent the same thing. And it has not been many years, comparatively, since even scientific men used the words synonymously. Modern chemistry and modern physics make a distinction, and define the two words differently.

"Force" is defined as the cause of motion, or the generator of momentum, while "energy" is expressed in the motion itself, in its power to do work. Force refers to the causes, while energy refers to work or the capacity to do work. The distinction is one that is difficult to make plain. Strictly de-

fined, force is any agency that can cause a motion, arrest a motion, or change the direction of a motion, while energy is motion or the capacity to become motion, and this carries with it the idea of work.—ELISHA GRAY *Nature's Miracles,* vol. ii, ch. 1, p. 1. (F. H. & H., 1900.)

1012. ENERGY DERIVED FROM SUN —*All Work Result of Heat.*—This great principle [the conservation of energy] enables us to realize the absolute interdependence of all the forces of Nature. It teaches us that there is no origination of force upon the earth, but that all energy either now comes to us from the sun, or was originated in the sun before our earth separated from it; and we are thus led to the conclusion that all work, all motion, every manifestation of power we see around us, are alike the effects of heat or of other radiant forces allied to it.—WALLACE *The Wonderful Century,* ch. vii, p. 53. (D. M. & Co., 1899.)

1013. ENERGY, ELECTRICAL, BATTERY A STORE OF—*Resemblance of Electricity to Fire—Force Stored in Coal or Zinc—Production of Power Costs Destruction of Material (as Such).*—Again, it may be said, with perfect truth, that every voltaic battery is a store of electrical energy. In a voltaic battery some metal is employed, generally zinc, which, when the battery is working, is acted on chemically by an acid. The effect of this chemical action is that the atoms of the metal combine with the oxygen of the acid; and by the act of combination an electric current is generated. . . . In the case of coal, we have carbon and hydrogen existing apart from oxygen, with a chemical force tending to make them combine, under suitable conditions. We set up these conditions when we light a fire: the chemical force then comes into action; the carbon and hydrogen rush to meet the oxygen; and in the clash of atoms heat is developed. Similarly, in the voltaic battery, we have zinc existing apart from oxygen, with a chemical force tending to pull them together. We bring this force into action when we arrange the cells of our battery and make the necessary connections; the atoms of zinc and oxygen then clash together, and, by the energy of their collision, an electric current is generated. Thus it is clear that, exactly in the same sense in which heat energy is said to be stored in a lump of coal, it may also be said that electrical energy is stored in the zinc plates of a battery. It is worth observing, too, that both cases furnish a striking illustration of a universal law of Nature. We cannot use our store of energy, and keep our store, at the same time. We cannot get heat from coal except by a process in which the coal is burned, and ceases to exist as coal. And so, too, we cannot get an electric current from our zinc plates except by a process in which the zinc is gradually consumed, and ceases to exist as zinc.—MOLLOY *The Storing of Electrical Energy,* p. 48. (Hum., 1889.)

1014. ENERGY, MANUFACTURE OF, IMPOSSIBLE—*Fallacy of Perpetual Motion.*—One result of the due apprehension of our personal helplessness will be that we shall no longer waste our time over the impossible task of manufacturing energy for ourselves. Our science will bring to an abrupt end the long series of severe experiments in which we have indulged in the hope of finding a perpetual motion. And having decided upon this once for all, our first step in seeking a more satisfactory state of things must be to find a new source of energy. Following Nature, only one course is open to us. We must refer to environment. The natural life owes all to environment, so must the spiritual. Now the environment of the spiritual life is God. As Nature therefore forms the complement of the natural life, God is the complement of the spiritual.—DRUMMOND *Natural Law in the Spiritual World,* essay 7, p. 244. (H. Al.)

1015. ENERGY OF POSITION—*Water at High Level Able To Do Work—Crossbow Bent—Watch Wound Up.*—Let us suppose there are two mills, one with a large pond of water near it and at a high level, while the other has also a pond, but at a lower level than itself. We need hardly ask which of the two is likely to work—clearly the one with the pond at a low level can derive from it no advantage whatever, while the other may use the high-level pond, or head of water, as this is sometimes called, to drive its wheel and do its work. There is, thus, a great deal of work to be got out of water high up—real substantial work, such as grinding corn or thrashing it, or turning wood or sawing it. On the other hand, there is no work at all to be got from a pond of water that is low down. [By virtue of the force of gravity] a stone high up, or a head of water, is in a position of advantage, and has the power of doing work as it falls to a lower level. But there are other forces besides gravity, and, with respect to these, bodies may be in a position of advantage and be able to do work just as truly as the stone, or the head of water, in the case before mentioned.

Let us take, for instance, the force of elasticity, and consider what happens in a crossbow. When this is bent, the bolt is evidently in a position of advantage with regard to the elastic force of the bow; and, when it is discharged, this energy of position of the bolt is converted into energy of motion, just as, when a stone on the top of a house is allowed to fall, its energy of position is converted into that of actual motion.

In like manner a watch wound up is in a position of advantage with respect to the elastic force of the mainspring, and as the

wheels of the watch move, this is gradually converted into energy of motion.—STEWART *The Conservation of Energy*, ch. 2, p. 377. (Hum., 1880.)

1016. ——— ——— *Water-wheel vs. Windmill—Accumulated Power Gives Independence—Analogy of Official or Social Position or Wealth in Human Life.*—It is, in fact, the fate of all kinds of energy of position to be ultimately converted into energy of motion.

The former may be compared to money in a bank, or capital, the latter to money which we are in the act of spending; and just as, when we have money in a bank, we can draw it out whenever we want it, so, in the case of energy of position, we can make use of it whenever we please. To see this more clearly, let us compare together a water-mill driven by a head of water and a windmill driven by the wind. In the one case we may turn on the water whenever it is most convenient for us, but in the other we must wait until the wind happens to blow. The former has all the independence of a rich man; the latter all the obsequiousness of a poor one. If we pursue the analogy a step further, we shall see that the great capitalist or the man who has acquired a lofty position is respected because he has the disposal of a great quantity of energy; and that whether he be a nobleman or a sovereign or a general in command, he is powerful only from having something which enables him to make use of the services of others. When the man of wealth pays a laboring man to work for him, he is in truth converting so much of his energy of position into actual energy, just as a miller lets out a portion of his head of water in order to do some work by its means.—STEWART *Conservation of Energy*, ch. 2, p. 378. (Hum., 1880.)

1017. ENERGY OF SUN—*Seemingly Undiminished—Immutability in the Midst of Change.*—Multiplying all our powers by millions of millions, we do not reach the sun's expenditure. And still, notwithstanding this enormous drain, in the lapse of human history we are unable to detect a diminution of his store. Measured by our largest terrestrial standards, such a reservoir of power is infinite; but it is our privilege to rise above these standards, and to regard the sun himself as a speck in infinite extension—a mere drop in the universal sea. We analyze the space in which he is immersed, and which is the vehicle of his power. We pass to other systems and other suns, each pouring forth energy like our own, but still without infringement of the law, which reveals immutability in the midst of change, which recognizes incessant transference or conversion, but neither final gain nor loss. The energy of Nature is a constant quality, and the utmost man can do in the pursuit of physical truth, or in the applications of physical knowledge, is to shift the constituents of the never-varying total, sacrificing one if he would produce another. The law of conservation rigidly excludes both creation and annihilation. Waves may change to ripples, and ripples to waves—magnitude may be substituted for number, and number for magnitude—asteroids may aggregate to suns, suns may invest their energy in floræ and faunæ, and floræ and faunæ may melt in air—the flux of power is eternally the same. It rolls in music through the ages, while the manifestations of physical life, as well as the display of physical phenomena, are but the modulations of its rhythm.—TYNDALL *Heat a Mode of Motion*, lect. 17, p. 535. (A., 1900.)

1018. ENERGY REQUIRED TO HOLD GASES TOGETHER IN WATER—Prior to experience, no one could suspect that two aeriform substances like oxygen and hydrogen could be obtained from water, and the discovery of the fact, near the beginning of this century, marks an era in the history of science. And even now, familiar as it is, this truth stands out as one of the most remarkable facts of Nature. Moreover, the wonder becomes still greater when we learn that water yields 1,800 times its volume of the two gases, and that these gases retain their aeriform condition so persistently that mechanical pressure alone cannot reduce them to the liquid condition; and still more the wonder grows when we learn further that the amount of energy required to decompose a pound of water into its constituent gases would be adequate to raise a weight of 5,314,200 pounds one foot high; and that, when these gases unite and the water is reproduced, this energy again becomes active.—COOKE *New Chemistry*, lect. 5, p. 114. (A., 1899.)

1019. ENERGY, SEEMING WASTE OF—*The Sun's Heat Poured into Empty Space—Might Warm Two Thousand Million Globes Like Ours.*—We have just seen the almost incomprehensible amount of heat which the sun must send the earth in order to warm its oceans and make green its continents; but how little this is to what passes by us! The earth as it moves on in its annual path continually comes into new regions, where it finds the same amount of heat already pouring forth; and this same amount still continues to fall into the empty space we have just quitted, where there is no one left to note it, and where it goes on in what seems to us utter waste. If, then, the whole annual orbit were set close with globes like ours, and strung with worlds like beads upon a ring, each would receive the same enormous amount the earth does now. But this is not all; for not only along the orbit, but above and below it, the sun sends its heat in seemingly incredible wastefulness, the final amount being expressible in the number of worlds like ours that it could warm like ours, which is 2,200,000,000.—LANGLEY *New Astronomy*, ch. 4, p. 95. (H. M. & Co., 1896.)

1020. ENERGY, THE CONSERVATION OF—The sum total of all causes working in Nature that can produce change in the physical world is as invariable as the totality of the store of matter. No manifestation of force can arise out of nothing, none can altogether disappear. All of the changes we observe consist in the fact that such a manifestation of force is expressed in some other way, it only assumes another form.—MEYER *Ueber Bestrebungen und Ziele der wissenschaftlichen Chemie*, p. 34. (Translated for *Scientific Side-Lights.)*

1021. ENERGY, THE FORM-GIVING ELEMENT IN MATTER—*Heat Makes the Difference between Solid, Liquid, and Gas.*—From the fact that all gases expand with heat and contract with cold, it is concluded that the ether-vibrations we term heat are the cause of the rapid motions of the gaseous molecules, and that if heat was entirely absent the motion would cease, and, ordinary cohesive attraction coming into play, the molecules would fall together and form a liquid or a solid. As a matter of fact, by intense cold, combined with pressure, all gases can be liquefied or solidified; and as, on the other hand, all the solid elements can be liquefied or vaporized by the intense heat of the electric furnace, we conclude that all matter when entirely deprived of heat is solid, and with sufficient heat becomes gaseous.—WALLACE *The Wonderful Century*, ch. 7, p. 55. (D. M. & Co., 1899.)

1022. ENGINEERING FEATS OF ANTIQUITY—*Power of Organized Labor—Time No Object.*—In the earliest engineering feats two facts must be sharply kept before the mind, to wit: That time was no object, and that there were no private buildings. Suppose that every laboring person in Chicago should be immediately withdrawn from all private work, and that they all should be organized to labor for ten years upon some government building as a memorial of the city's grandeur. One million hand-laborers would erect a pyramid containing fifteen thousand milliards of tons of earth, and the mechanics would put on the top of it a structure larger than all the monuments in Egypt combined.—MASON *Aboriginal American Mechanics (Memoirs of the International Congress of Anthropology*, p. 82). (Sch. P. C.)

1023. ENJOYMENT BY ILLUSION—*Made Happy by Attempting To Seem So.*—Let us examine one of these active illusions a little more fully. It would at first sight seem to be a perfectly simple thing to determine at any given moment whether we are enjoying ourselves, whether our emotional condition rises above the pleasure-threshold or point of indifference and takes on a positive hue of the agreeable or pleasurable. Yet there is good reason for supposing that people not unfrequently deceive themselves on this matter. It is, perhaps, hardly an exaggeration to say that most of us are capable of imagining that we are having enjoyment when we conform to the temporary fashion of social amusement. It has been cynically observed that people go into society less in order to be happy than to seem so, and one may add that in this semblance of enjoyment they may, provided they are not blasé, deceive themselves as well as others. The expectation of enjoyment, the knowledge that the occasion is intended to bring about this result, the recognition of the external signs of enjoyment in others—all this may serve to blind a man in the earlier stages of social amusement to his actual mental condition.—SULLY *Illusions*, ch. 8, p. 200. (A., 1897.)

1024. ENJOYMENT CONDUCIVE TO BENEVOLENCE—*Desire to Impart Pleasure.*—We do not conceive life to be so rich in enjoyments that it can afford to forego the cultivation of all those which address themselves to what M. Comte terms the egotistic propensities. On the contrary, we believe that a sufficient gratification of these, short of excess, but up to the measure which renders the enjoyment greatest, is almost always favorable to the benevolent affections. The moralization of the personal enjoyments we deem to consist, not in reducing them to the smallest possible amount, but in cultivating the habitual wish to share them with others, and with all others, and scorning to desire anything for oneself which is incapable of being so shared. There is only one passion or inclination which is permanently incompatible with this condition—the love of domination, or superiority, for its own sake; which implies, and is grounded on, the equivalent depression of other people. As a rule of conduct to be enforced by moral sanctions, we think no more should be attempted than to prevent people from doing harm to others, or omitting to do such good as they have undertaken. Demanding no more than this, society in any tolerable circumstances obtains much more; for the natural activity of human nature, shut out from all noxious directions, will expand itself in useful ones.—MILL *Positive Philosophy of Auguste Comte*, p. 131. (H. H. & Co., 1887.)

1025. ENJOYMENT OF NATURE LESS FREELY EXPRESSED IN GREEK THAN IN HEBREW POETRY—It has often been remarked that, altho the enjoyment derived from the contemplation of Nature was not wholly unknown to the ancients, the feeling was, nevertheless, much more rarely and less vividly expressed than in modern times. In his considerations on the poetry of the sentiments, Schiller thus expresses himself: "If we bear in mind the beautiful scenery with which the Greeks were surrounded, and remember the opportunities possessed by a people living in so genial a climate of entering into the free enjoyment of the contemplation of Nature, and observe how conformable were their mode of

thought, the bent of their imaginations, and the habits of their lives to the simplicity of Nature, which was so faithfully reflected in their poetic works, we cannot fail to remark with surprise how few traces are to be met among them of the sentimental interest with which we, in modern times, attach ourselves to the individual characteristics of natural scenery. The Greek poet is certainly, in the highest degree, correct, faithful, and circumstantial in his descriptions of Nature, but his heart has no more share in his words than if he were treating of a garment, a shield, or a suit of armor. Nature seems to interest his understanding more than his moral perceptions; he does not cling to her charms with the fervor and the plaintive passion of the poet of modern times." However much truth and excellence there may be in these remarks, they must not be extended to the whole of antiquity; and I moreover consider that we take a very limited view of antiquity when, in contradistinction to the present time, we restrict the term exclusively to the Greeks and Romans. A profound feeling of Nature pervades the most ancient poetry of the Hebrews and Indians, and exists, therefore, among nations of very different descent—Semitic and Indo-Germanic.—HUMBOLDT *Cosmos*, vol. ii, pt. i, p. 21. (H., 1897.)

1026. ENTHUSIASM OF YOUNG NATURALIST—*Fossil Winged Fish.*—Of all the organisms of the system [the Old Red Sandstone], one of the most extraordinary . . . is the *Pterichthys*, or winged fish, an ichthyolite which the writer had the pleasure of introducing to the acquaintance of geologists nearly three years ago, but which he first laid open to the light about seven years earlier. . . . I fain wish I could communicate to the reader the feeling with which I contemplated my first specimen. It opened with a single blow of the hammer; and there, on a ground of light-colored limestone, lay the effigy of a creature fashioned apparently out of jet, with a body covered with plates, two powerful looking arms, articulated at the shoulders, a head as entirely lost in the trunk as that of the ray or the sunfish, and a long, angular tail. My first-formed idea regarding it was, that I had discovered a connecting link between the tortoise and the fish—the body much resembles that of a small turtle; and why, I asked, if one formation gives us sauroid fishes, may not another give us chelonian ones? or if in the Lias we find the body of the lizard mounted on the paddles of the whale, why not find in the Old Red Sandstone the body of the tortoise mounted in a somewhat similar manner? The idea originated in error; but as it was an error which not many naturalists could have corrected at the time, it may be deemed an excusable one, more especially by such of my readers as may have seen well-preserved specimens of the creature.—MILLER *The Old Red Sandstone*, ch. 3, p. 42. (G. & L., 1851.)

1027. ——— ——— *Traces of the Ice-period in America.*—In the autumn of 1846, six years after my visit to Great Britain in search of glaciers, I sailed for America. When the steamer stopped at Halifax, eager to set foot on the new continent so full of promise for me, I sprang on shore and started at a brisk pace for the heights above the landing. On the first undisturbed ground, after leaving the town, I was met by the familiar signs, the polished surfaces, the furrows and scratches, the line-engraving of the glacier, so well known in the Old World; and I became convinced of what I had already anticipated as the logical sequence of my previous investigations, that here also this great agent had been at work, altho it was only after a long residence in America, and repeated investigations of the glacial phenomena in various parts of the country, that I fully understood the universality of its action.—AGASSIZ *Geological Sketches*, ser. ii, p. 77. (H. M. & Co., 1896.)

1028. ENTOMOLOGIST DECEIVED—*Protective Mimicry of Caterpillars.*—Some of the most curious examples of minute imitation are afforded by the caterpillars of the geometer moths, which are always brown or reddish, and resemble in form little twigs of the plant on which they feed. They have the habit, when at rest, of standing out obliquely from the branch, to which they hold on by their hind pair of prolegs or claspers, and remain motionless for hours. Speaking of these protective resemblances Mr. Jenner Weir says: "After being thirty years an entomologist I was deceived myself, and took out my pruning-scissors to cut from a plum-tree a spur which I thought I had overlooked. This turned out to be the larva of a geometer two inches long. I showed it to several members of my family, and defined a space of four inches in which it was to be seen, but none of them could perceive that it was a caterpillar."—WALLACE *Darwinism*, ch. 8, p. 139. (Hum., 1889.)

1029. ENVIRONMENT, ADAPTATION TO CHANGES OF—*Stomach of Sea-gull—Gizzard of Pigeon.*—Hunter, for example, in a classical experiment, so changed the environment of a sea-gull by keeping it in captivity that it could only secure a grain diet. The effect was to modify the stomach of the bird, normally adapted to a fish diet, until in time it came to resemble in structure the gizzard of an ordinary grain-feeder, such as the pigeon. Holmgrén, again, reversed this experiment by feeding pigeons for a lengthened period on a meat diet, with the result that the gizzard became transformed into the carnivorous stomach.—DRUMMOND *Natural Law in the Spiritual World*, essay 7, p. 232. (H. Al.)

1030. ENVIRONMENT AFFECTING MAN—*Adaptation of Races to Climate and Locality.*—That certain races are constitutionally fit and others unfit for certain climates,

is a fact which the English have but too good reason to know, when on the scorching plains of India they themselves become languid and sickly, while their children have soon to be removed to some cooler climate that they may not pine and die. It is well known also that races are not affected alike by certain diseases. While in Equatorial Africa or the West Indies the coast fever and yellow fever are so fatal or injurious to the new-come Europeans, the negroes and even mulattoes are almost untouched by this scourge of the white nations. On the other hand, we English look upon measles as a trifling complaint, and hear with astonishment of its being carried into Fiji, and there, aggravated no doubt by improper treatment, sweeping away the natives by thousands. It is plain that nations moving into a new climate, if they are to flourish, must become adapted in body to the new state of life; thus in the rarefied air of the high Andes more respiration is required than in the plains, and in fact tribes living there have the chest and lungs developed to extraordinary size. Races, tho capable of gradual acclimatization, must not change too suddenly the climate they are adapted to. With this adaptation to particular climates the complexion has much to do, fitting the negro for the tropics and the fair-white for the temperate zone; tho, indeed, color does not always vary with climate, as where in America the brown race extends through hot and cold regions alike. Fitness for a special climate, being matter of life or death to a race, must be reckoned among the chief of race-characters.—TYLOR *Anthropology*, ch. 3, p. 73. (A., 1899.)

1031. ENVIRONMENT ALONE DOES NOT DEVELOP GENIUS—The remarkable scientific activity manifested by the Arabs in all branches of practical astronomy is to be ascribed less to native than to Chaldean and Indian influences. Atmospheric conditions merely favored that which had been called forth by mental qualifications, and by the contact of highly gifted races with more civilized neighboring nations. How many rainless portions of tropical America enjoy a still more transparent atmosphere than Egypt, Arabia, and Bokhara! A tropical sky, and the eternal clearness of the heavens, radiant in stars and nebulous spots, undoubtedly everywhere exercise an influence on the mind, but they can only lead to thought, and to the solution of mathematical propositions, where other internal and external incitements, independent of climatic relation, affect the national character, and where the requirements of religious and agricultural pursuits make the exact division of time a necessity prompted by social conditions. Among calculating commercial nations (as the Phenicians), among constructive nations, partial to architecture and the measurement of land (as the Chaldeans and Egyptians), empirical rules of arithmetic and geometry were early discovered; but these are merely capable of preparing the way for the establishment of mathematical and astronomical science. It is only in the later phases of civilization that the established regularity of the changes in the heavens is known to be reflected in terrestrial phenomena. . . . The conviction entertained in all climates of the regularity of the planetary movements has contributed more than anything else to lead man to seek similar laws of order in the moving atmosphere, in the oscillations of the ocean, in the periodic course of the magnetic needle, and in the distribution of organisms over the earth's surface.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 221. (H., 1897.)

1032. ENVIRONMENT, ARTIFICIAL, A BONDAGE—*Possessions May Possess.*—Only to a certain extent does possession make a man freer, more independent. A step farther and possession becomes master, the possessor a slave required to sacrifice his time and thought, and find himself responsible to connections, nailed to place, incorporated in a state, all of which may be opposed to the essential requirements of his inmost nature.—SCHOPENHAUER, according to SCHWARZ, *Psychologie des Willens, a Lecture.* (Translated for *Scientific Side-Lights.)*

1033. ENVIRONMENT, BIRD'S CORRESPONDENCE WITH—*Man a Mass of Correspondences.*—The bird, again, which is higher in the scale of life, corresponds with a wider environment. The stream is real to it, and the insect. It knows what lies behind the hill; it listens to the love-song of its mate. And to much besides beyond the simple world of the tree this higher organism is alive. The bird, we should say, is more living than the tree; it has a correspondence with a larger area of environment. But this bird-life is not yet the highest life. Even within the immediate bird-environment there is much to which the bird must still be held to be dead. Introduce a higher organism, place man himself within this same environment, and see how much more living he is. A hundred things which the bird never saw in insect, stream, and tree appeal to him. Each single sense has something to correspond with. Each faculty finds an appropriate exercise. Man is a mass of correspondences, and because of these, because he is alive to countless objects and influences to which lower organisms are dead, he is the most living of all creatures. —DRUMMOND *Natural Law in the Spiritual World*, essay 4, p. 139. (H. Al.)

1034. ENVIRONMENT CANNOT ORIGINATE ADAPTATION—*Tubular Flower Cannot Produce Humming-bird's Bill.*—But correlation in this sense [*i. e.*, between different parts of the same organism] helps but a little way indeed in conceiving the origin of a new species. There might be the most minute and perfect harmony between

the changes effected in an animal newly born without those changes tending even in the most remote degree towards the establishment of a new form of life. In order to that establishment there must be another correlation, and a correlation of a higher kind. There must be a correlation between those changes and all the outward conditions amidst which the new form is to be placed and live. If this correlation fails the new form will die. Yet, so far as we can see, this kind of correlation is without any physical cause. It is not necessarily involved, as the other kind of correlation is, in the very idea of growth. On the contrary, it is not only entirely separable in thought, but, as we see in monstrosities, it is sometimes separated in fact. We have no conception of any force emanating from external things which shall mold the structure of an organism in harmony with themselves. Mr. Darwin freely confesses this, and says that many considerations "incline him to lay very little weight on the direct action of the conditions of life" in producing variety of form. We can conceive, dimly indeed, but still we can conceive, how in the humming-birds a special form of wing shall be correlated with a special form of bill. But we have no conception whatever how a special form of bill should be correlated with a special form of flower from which the bill is to extract its food. Mr. Darwin has shown how an improved bill, when once produced, will be preserved by finding external conditions to which it is adapted. But he has not shown, and he frankly confesses he has no idea, how the adapted variation of bill comes to be born at all.—ARGYLL *Reign of Law*, ch. 5, p. 149. (Burt.)

1035. ENVIRONMENT CHANGED BY EVOLUTION—*A Continually New Environment as One Climbs the Mountain.*—For what is most of all essential to remember is that not only is environment the prime factor in development, but that the environment itself rises with every evolution of any form of life. To regard the environment as a fixed quantity and a fixed quality is, next to ignoring the altruistic factor, the cardinal error of evolutional philosophy. With every step a climber rises up a mountain-side his environment must change.—DRUMMOND *Ascent of Man*, ch. 10, p. 325. (J. P., 1900.)

1036. ENVIRONMENT, CORRESPONDENCE WITH—*Man May Change Environment—Intelligent Volition May Secure More of Life.*—The essential characteristic of a living organism, according to these definitions [of Herbert Spencer's "Principles of Biology," vol. i, p. 74], is that it is in vital connection with its general surroundings. A human being, for instance, is in direct contact with the earth and air, with all surrounding things, with the warmth of the sun, with the music of birds, with the countless influences and activities of Nature and of his fellow men. In biological language, he is said thus to be "in correspondence with his environment." . . . Now it is in virtue of this correspondence that he is entitled to be called alive. So long as he is in correspondence with any given point of his environment, he lives. To keep up this correspondence is to keep up life. If his environment changes he must instantly adjust himself to the change. And he continues living only as long as he succeeds in adjusting himself to the "simultaneous and successive changes in his environment" as these occur. What is meant by a change in his environment may be understood from an example, which will at the same time define more clearly the intimacy of the relation between environment and organism. Let us take the case of a civil-servant whose environment is a district in India. It is a region subject to occasional and prolonged droughts resulting in periodical famines. When such a period of scarcity arises, he proceeds immediately to adjust himself to this external change. Having the power of locomotion, he may remove himself to a more fertile district, or, possessing the means of purchase, he may add to his old environment by importation the "external relations" necessary to continued life. But if from any cause he fails to adjust himself to the altered circumstances, his body is thrown out of correspondence with his environment, his "internal relations" are no longer adjusted to his "external relations," and his life must cease.—DRUMMOND *Natural Law in the Spiritual World*, essay 4, p. 132. (H. Al.)

1037. ENVIRONMENT, RELATIONS OF ANIMAL TO—The relation between animals and their environment is now a question of such great interest and importance that it is necessary in any description of the fauna of a particular region to consider its physical conditions and the influence that it may be supposed to have had in producing the characteristics of the fauna.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 18. (A., 1894.)

1038. ENVIRONMENT, SINFUL, CONTACT WITH—*Linked to Evil by a Single Correspondence.*—As a general rule men are linked to evil mainly by a single correspondence. Few men break the whole law. Our natures, fortunately, are not large enough to make us guilty of all, and the restraints of circumstances are usually such as to leave a loophole in the life of each individual for only a single habitual sin. But it is very easy to see how this reduction of our intercourse with evil to a single correspondence blinds us to our true position. Our correspondences, as a whole, are not with evil, and in our calculations as to our spiritual condition we emphasize the many negatives rather than the single positive. One little weakness, we are apt to fancy, all men must be allowed, and we even claim a

certain indulgence for that apparent necessity of nature which we call our besetting sin. Yet to break with the lower environment at all, to many, is to break at this single point. It is the only important point at which they touch it, circumstances or natural disposition making habitual contact at other places impossible. The sinful environment, in short, to them means a small but well-defined area. Now if contact at this point be not broken off, they are virtually in contact still with the whole environment.—DRUMMOND *Natural Law in the Spiritual World*, essay 5, p. 167. (H. Al.)

1039. ENVIRONMENT, SPIRITUAL—*Lack of Correspondence is Spiritual Death.*—Now follows a momentous question. Is man in correspondence with the whole environment? When we reach the highest living organism, is the final blow dealt to the kingdom of death? Has the last acre of the infinite area been taken in by his finite faculties? Is his conscious environment the whole environment? Or is there, among these outermost circles, one which with his multitudinous correspondences he fails to reach. If so, this is death. The question of life or death to him is the question of the amount of remaining environment he is able to compass. If there be one circle or one segment of a circle which he yet fails to reach, to correspond with, to know, to be influenced by, he is, with regard to that circle, or segment, dead.—DRUMMOND *Natural Law in the Spiritual World*, essay 4, p. 140. (H. Al.)

1040. ENVIRONMENT, SUITABLE, A NECESSITY OF LIFE—*Injurious Organisms Live Only Where They Find a Favorable Medium Awaiting Them.*—In the very earliest days of the study of micro-organisms it was observed that they mostly congregate where there is pabulum for their nourishment. The reason why fluids such as milk, and dead animal matter such as a carcass, and living tissues such as a man's body contain so many microbes is because each of these three media is favorable to their growth. Milk affords almost an ideal food and environment for microbes. Its temperature and constitution frequently meet their requirements. Dead animal matter, too, yields a rich diet for some species (saprophytes). In the living tissues bacteria obtain not only nutriment, but a favorable temperature and moisture. Outside the human body it has been the endeavor of bacteriologists to provide media as like the above as possible, and containing many of the same elements of food. Thus the life-history may be carried on outside the body and under observation. —NEWMAN *Bacteria*, ch. 1, p. 20. (G. P. P., 1899.)

1041. ——— ——— *Requisites for Natural Life—Conditions of Vitality.*—To understand the sustaining influence of environment in the animal world, one has only to recall what the biologist terms the extrinsic or subsidiary conditions of vitality. Every living thing normally requires for its development an environment containing air, light, heat, and water. In addition to these, if vitality is to be prolonged for any length of time, and if it is to be accompanied with growth and the expenditure of energy, there must be a constant supply of food. When we simply remember how indispensable food is to growth and work, and when we further bear in mind that the food-supply is solely contributed by the environment, we shall realize at once the meaning and the truth of the proposition that without environment there can be no life. Seventy per cent. at least of the human body is made of pure water, the rest of gases and earths. These have all come from environment. Through the secret pores of the skin two pounds of water are exhaled daily from every healthy adult. The supply is kept up by environment. The environment is really an unappropriated part of ourselves. Definite portions are continuously abstracted from it and added to the organism. And so long as the organism continues to grow, act, think, speak, work, or perform any other function demanding a supply of energy, there is a constant, simultaneous, and proportionate drain upon its surroundings.—DRUMMOND *Natural Law in the Spiritual World*, essay 7, p. 234. (H. Al.)

1042. ——— ——— *Requisites for Spiritual Life—The Soul's Environment God.*—In the spiritual world especially, he will be wise who courts acquaintance with the most ordinary and transparent facts of Nature; and in laying the foundations for a religious life he will make no unworthy beginning who carries with him an impressive sense of so obvious a truth as that without environment there can be no life. For what does this amount to in the spiritual world? Is it not merely the scientific restatement of the reiterated aphorism of Christ. "Without Me ye can do nothing"? There is in the spiritual organism a principle of life; but that is not self-existent. It requires a second factor, a something in which to live and move and have its being, an environment. Without this it cannot live or move or have any being. Without environment the soul is as the carbon without the oxygen, as the fish without the water, as the animal frame without the extrinsic conditions of vitality. And what is the spiritual environment? It is God. Without this, therefore, there is no life, no thought, no energy, nothing—"without Me ye can do nothing."—DRUMMOND *Natural Law in the Spiritual World*, essay 7, p. 237. (H. Al.)

1043. EPOCH CREATED BY GREAT DISCOVERIES—*The Telescope, Jupiter's Satellites, the Disk of Venus, Gravitation.*—The whole of the seventeenth century, whose commencement was brilliantly signalized by the great discovery of the telescope, together with the immediate results by which it was

attended—from Galileo's observation of Jupiter's satellites, of the crescentic form of the disk of Venus, and the spots on the sun, to the theory of gravitation discovered by Newton—ranks as the most important epoch of a newly created physical astronomy. This period constitutes, therefore, from the unity of the efforts made toward the observation of the heavenly bodies, and in mathematical investigations, a sharply defined section in the great process of intellectual development, which, since then, has been characterized by an uninterrupted progress.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 201. (H., 1897.)

1044. EPOCHS, BREACHES OF CONTINUITY—*Sudden Developments of Human Power—Great Men in Clusters.*—It is an order of facts observable in the progress of mankind, that long ages of comparative silence and inaction are broken up, and brought to an end, by shorter periods of almost preternatural activity. And that activity is generally spent in paths of investigation, which, tho independent, are converging. Different minds, pursuing different lines of thought, find themselves meeting upon common ground. Such, in respect to literature, was the period of the Revival of Learning: such, in respect to religion, was the period of the Reformation; such, in respect to the abstract sciences, was the period of Tycho Brahe, of Galileo, and Kepler. Hardly less memorable than these, certainly not less powerful, as affecting the condition of society, were those few years in the last quarter of the eighteenth century which were marked by such an extraordinary burst of mechanical invention. Hargreaves, and Arkwright, and Watt, and Crompton, and Cartwright were all contemporaries. They were all working at the same time, and in the same direction. Out of their inventions there arose for the first time what is now known as the factory system; and out of the factory system arose a condition of things, as affecting human labor, which was entirely new in the history of the world.—ARGYLL *Reign of Law*, ch. 7, p. 204. (Burt.)

1045. EQUALITY, MENTAL, A DELUSION—*Cruel Result of Such Belief—Tyranny of Bad Mental Organization.*—Perhaps of all the erroneous notions concerning mind which metaphysics has engendered or abetted, there is none more false than that which tacitly assumes or explicitly declares that men are born with equal original mental capacity; opportunities and education determining the differences of subsequent development. The opinion is as cruel as it is false. What man can by taking thought add one cubit either to his mental or to his bodily stature? Multitudes of human beings come into the world weighted with a destiny against which they have neither the will nor the power to contend; they are the step-children of Nature, and groan under the worst of all tyrannies—the tyranny of a bad organization. Men differ, indeed, in the fundamental characters of their minds, as they do in the features of their countenances, or in the habits of their bodies; and between those who are born with the potentiality of a full and complete mental development, under favorable circumstances, and those who are born with an innate incapacity of mental development, under any circumstances, there exists every gradation. What teaching could ever raise the congenital idiot to the common level of human intelligence? What teaching could ever keep the inspired mind of the man of genius at that level?—MAUDSLEY *Body and Mind*, lect. 2, p. 43. (A., 1898.)

1046. EQUILIBRIUM OF NATURE—*Chance Does Not Give Order and Progress—The Loaded Dice.*—It has been well said that if a pair of dice were to turn up aces a hundred times in succession, any reasonable spectator would conclude that they were loaded dice; so if countless millions of atoms and thousands of species, each including within itself most complex arrangement of parts, turn up in geological time in perfectly regular order and a continued gradation of progress, something more than chance must be implied. It is to be observed here that every species of animal or plant, of however low grade, consists of many coordinated parts in a condition of the nicest equilibrium. Any change occurring which produces unequal or disproportionate development, as the experience of breeders of abnormal varieties of animals and plants abundantly proves, imperils the continued existence of the species. Changes must, therefore, in order to be profitable, affect the parts of the organism simultaneously and symmetrically. The chances of this may well be compared to the casting of aces a hundred times in succession, and are so infinitely small as to be incredible under any other supposition than that of intelligent design.—DAWSON *Facts and Fancies in Modern Science*, lect. 3, p. 122. (A. B. P. S.)

1047. EQUIPMENT FOR DESTRUCTION—*Deceptive Coloration among Birds.*—Deceptive, or, as Poulton terms it, "aggressive" coloration is perhaps best illustrated by common flycatchers (*Tyrannidæ*). Altho these birds live in and about trees, they are, as a rule, quietly attired in olive-green or olive-gray, and are quite unlike the brilliantly clad, fruit-eating tanagers, orioles, parrots, and other birds that may be found near them. Insects are therefore more likely to come within snapping distance than if these birds were conspicuously colored. In the same manner we may explain the colors of hawks, which are never brightly plumaged. It is well known that many arctic animals become white on the approach of winter. With ptarmigans this is doubtless an instance of protective coloration, but the

snowy owl, who feeds on the ptarmigan, may be said to illustrate deceptive coloration.—CHAPMAN *Bird-Life*, ch. 3, p. 44. (A., 1900.)

1048. EQUIVALENCE OF FORCES—*Heat and Electricity.*—If I should set an emery-wheel to revolving and hold a piece of steel against it, the piece of steel would become heated and incandescent particles would fly off, making a brilliant display of fireworks. The heat that has been developed is the measure of the mechanical energy that I have used against the emery-wheel. Now, let us substitute for the emery-wheel another wheel of the same size made of vulcanized rubber, glass, or resin. I set it to revolving at the same speed, and instead of the piece of steel, I now hold a silk handkerchief or a catskin against the wheel with the same force that I did the steel. If now I provide a Leyden jar and some points to gather up the electricity that will be produced (instead of the heat generated in the other case), it would be found that the energy developed in the one case would exactly balance that of the other, if it were all gathered up and put into work. The electricity stored in the jar is in a state of strain, like a bent bow, and will recoil, when it has a chance, with a power commensurate with the time it has been storing and the amount of energy used in pressing against the wheel. If now I connect my two hands, one with the inside and the other with the outside of the jar, this stored energy will strike me with a force equal to all the energy I have previously expended in pressing against the wheel, minus the loss in heat. If I did it for a long enough time this electrical spring would be wound up to such a tension that the recoil would destroy life if one put himself in the path of its discharge.—ELISHA GRAY *Nature's Miracles*, vol. iii, ch. 5, p. 44. (F. H. & H., 1900.)

1049. EROSION BY SAND-LADEN WATER—*Minute Particles Cut through Solid Cliff—Mighty Effect from Trivial Cause.*—This power of erosion, so strikingly displayed when sand is urged by air, renders us better able to conceive its action when urged by water. The erosive power of a river is vastly augmented by the solid matter carried along with it. Sand or pebbles, caught in a river vortex, can wear away the hardest rock; "pot-holes" and deep cylindrical shafts being thus produced. An extraordinary instance of this kind of erosion is to be seen in the Val Tournanche, above the village of this name. The gorge at Handeck has been thus cut out.—TYNDALL *Fragments of Science*, vol. i, ch. 7, p. 196. (A., 1900.)

1050. ERROR, CUMULATIVE RESULT OF—*Slight Inaccuracy Vitiates All Results in Space and Time.*—Our estimates of the masses of the heavenly bodies also depend upon a knowledge of the sun's distance from the earth. The quantity of matter in a star or planet is determined by calculations whose fundamental data include the distance between the investigated body and some other body whose motion is controlled or modified by it; and this distance generally enters into the computation by its cube, so that any error in it involves a more than threefold error in the resulting mass. An uncertainty of one per cent. in the sun's distance implies an uncertainty of more than three per cent. in every celestial mass and every cosmical force.

Error in this fundamental element propagates itself in time also, as well as in space and mass. . . . If, for instance, we should find as the result of calculation with the received data, that two millions of years ago the eccentricity of the earth's orbit was at a maximum, and the perihelion so placed that the sun was nearest during the northern winter (a condition of affairs which it is thought would produce a glacial epoch in the southern hemisphere), it might easily happen that our results would be exactly contrary to the truth, and that the state of affairs indicated did not occur within ten thousand years of the specified date—and all because in our calculation the sun's distance, or the solar parallax by which it is measured, was assumed half of one per cent. too great or too small.—YOUNG *The Sun*, ch. 2, p. 11. (A., 1898.)

1051. ERROR, DEFINITE, MORE HELPFUL THAN INDECISION—None of Bacon's aphorisms shows a clearer insight into the relations between the human mind and the external world than that which declares ["Novum Organum," lib. ii, aph. 20], "Truth to emerge sooner from error than from confusion." A definite theory (even if a false one) gives holding-ground to thought. Facts acquire a meaning with reference to it. It affords a motive for accumulating them and a means of coordinating them; it provides a framework for their arrangement, and a receptacle for their preservation, until they become too strong and numerous to be any longer included within arbitrary limits, and shatter the vessel originally framed to contain them.

Such was the purpose subserved by Herschel's theory of the sun. It helped to clarify ideas on the subject. The turbid sense of groping and viewless ignorance gave place to the lucidity of a plausible scheme.—CLERKE *History of Astronomy*, pt. i, ch. 3, p. 67. (Bl., 1893.)

1052. ERROR, HONEST, LEADS TO KNOWLEDGE—*Alchemists Discover Chemistry — Atoms in Greek Philosophy.*—The Greek philosophers expressed their ideas of the states of matter by the four elements, fire, air, water, earth; and they also had learned or invented the doctrine of matter being made up of atoms—a principle now more influential than ever in modern lecture-rooms. The successors of the Greeks were the Arabic alchemists, and their dis-

ciples in medieval Christendom. Their belief that matter might be transmuted or transformed led many of them to spend their lives among their furnaces and alembics in the attempt to turn baser metals into gold. To modern chemists, who would not be surprised to find all the many so-called elements proved to be forms of one matter, the alchemists' idea does not seem quite unreasonable in itself, and practically it led them to the pursuit of truth by experiment, so that tho they found no philosopher's stone, they were repaid by discoveries such as alcohol, ammonia, sulfuric acid. Their method, being founded on trials of real fact, cleared itself more and more from the magical folly it had grown up with, and the alchemist prepared the way for the later chemist.—TYLOR *Anthropology*, ch. 13, p. 328. (A., 1899.)

1053. ERROR INSEPARABLE FROM INVESTIGATION—Cope has been much criticized for the mistakes and false generalizations he made. Unquestionably he did make many. But error seems to be inseparable from investigation, and if he made more than the other great masters, he covered more ground and did more work. He was also, it must be admitted, more hasty than some others in that he availed himself of the more frequent means of publication he enjoyed.—GILL *Proc. Amer. Assoc. for the Advancement of Science*, vol. xlvi. (1897.)

1054. ERROR MAGNIFIED IN POPULAR BELIEF—*Supposed Hollow Interior of the Earth—"Symmes's Hole."*—Leslie has ingeniously conceived the nucleus of the world to be a hollow sphere, filled with an assumed "imponderable matter, having an enormous force of expansion." These venturesome and arbitrary conjectures have given rise, in wholly unscientific circles, to still more fantastic notions. The hollow sphere has by degrees been peopled with plants and animals, and two small subterranean revolving planets—Pluto and Proserpine—were imaginatively supposed to shed over it their mild light; as, however, it was further imagined that an ever-uniform temperature reigned in these internal regions, the air, which was made self-luminous by compression, might well render the planets of this lower world unnecessary. Near the north pole, at 82° latitude, whence the polar light emanates, was an enormous opening, through which a descent might be made into the hollow sphere, and Sir Humphry Davy and myself were even publicly and frequently invited by Captain Symmes to enter upon this subterranean expedition: so powerful is the morbid inclination of men to fill unknown spaces with shapes of wonder, totally unmindful of the counter-evidence furnished by well-attested facts and universally acknowledged natural laws.—HUMBOLDT *Cosmos*, vol. i, p. 171. (H., 1897.)

1055. ERROR OF CLAIMING TOO MUCH—*Unsupported Assumptions Discredit True Doctrines—The Atomic Theory Overloaded.*—Speculators have often erred in attempting to elaborate their hypotheses too fully, and, by making assumptions which have afterwards proved to be improbable or untenable, have brought discredit on views which, in their essentials, were of great value. . . . All we can say at present is that by no chemical or physical process known to us do atoms undergo division or transformation to an extent appreciable by chemical methods. An atom of carbon always acts with the combining weight 12; if it consist of several independent parts, we do not know it, because, in all reactions thus far known, these parts always act together. The idea of the transmutation of the elements, while resting at present on a very slender basis, is entirely justifiable as a working hypothesis.—STOKES *The Atomic Theory from the Chemical Standpoint in Science*. N. S. vol. xi, No. 277, Apr. 20, 1900.

1056. ERROR ONCE UNIVERSAL—*Frogs, Eels, Shell-fish, Caterpillars, Serpents, Rats, and Mice Credited with Spontaneous Generation.*—The checks which experience alone can furnish being absent, the spontaneous generation of creatures quite as high as the frog in the scale of being was assumed for ages to be a fact. Here, as elsewhere, the dominant mind of Aristotle stamped its notions on the world at large. For nearly twenty centuries after him men found no difficulty in believing in cases of spontaneous generation which would now be rejected as monstrous by the most fanatical supporter of the doctrine. Shell-fish of all kinds were considered to be without parental origin. Eels were supposed to spring spontaneously from the fat ooze of the Nile. Caterpillars were the spontaneous products of the leaves on which they fed; while winged insects, serpents, rats, and mice were all thought capable of being generated without sexual intervention.—TYNDALL *Fragments of Science*, vol. ii, ch. 13, p. 290. (A., 1900.)

1057. ERRORS OF EDUCATORS—*Man Viewed as an Instrument—Knowledge Valued More than Culture.*—Now the various opinions which prevail concerning the comparative utility of human sciences and studies, have all arisen from two errors. The first of these consists in viewing man, not as an end unto himself, but merely as a mean organized for the sake of something out of himself; and, under this partial view of human destination, those branches of knowledge obtain exclusively the name of useful which tend to qualify a human being to act the lowly part of a dexterous instrument. The second, and the more dangerous of these errors, consists in regarding the cultivation of our faculties as subordinate to the acquisition of knowledge, instead of regarding the possession of knowledge as subordinate to the cultivation of our faculties; and, in consequence of this error, those sciences which afford a greater number of

more certain facts have been deemed superior in utility to those which bestow a higher cultivation on the higher faculties of the mind.—HAMILTON *Metaphysics*, lect. 1, p. 3. (G. & L., 1859.)

1058. ERRORS OF SCIENTISTS—*A Classification that Would Include the Hog among Ruminants.*—Cuvier taught that there was always a coordination between the various systems of the animal frame and that, from the remains or impress of one part, the approximate structure of the other parts could be inferred. He even pushed this doctrine to such an extreme that he overlooked some obvious counter-facts. One such case is so remarkable, because it originated with Cuvier and was indorsed by Huxley, that it is worthy of mention here, and Huxley's introduction to it and translation of it may be given [from his "Introduction to the Classification of Animals," 1869, ch. 1]:

" . . . I doubt if any one would have divined, if untaught by observation, that all ruminants have the foot cleft, and that they alone have it; . . . so that now, whoso sees merely the print of a cleft foot may conclude that the animal which left this impression ruminated, and this conclusion is as certain as any other in physics or morals."

Some men, with much less knowledge than either Cuvier or Huxley, may at once recall living exceptions to the positive statements as to the coordination of the "foot cleft" with the other characters specified. One of the most common of domesticated animals—the hog—would come up before the "mind's eye," if not the actual eye at the moment, to refute any such correlation as was claimed. Nevertheless, notwithstanding the fierce controversial literature centered on Huxley, no allusion appears to have been made to the *lapsus*. Yet every one will admit that the hog has the "foot cleft" as much as any ruminant, but the "form of the teeth" and the form of some vertebræ are quite different from those of the ruminants, and of course the multiple stomach and adaptation for rumination do not exist in the hog. That any one mammalogist should make such a slip is not very surprising, but that a second equally learned should follow in his steps is a singular psychological curiosity.—GILL *Edward Drinker Cope, Naturalist*, in *Proc. Amer. Assoc. for the Advancement of Science*, vol. xlvi, p. 17. (1897.)

1059. ——— ——— *All Nebulæ Once Supposed Resolvable—"Island Universes"—Correction of Error by Spectroscope.*—Altho Lord Rosse himself rejected the inference that because many nebulæ had been resolved, all are resolvable, very few imitated his truly scientific caution; and the results of Bond's investigations with the Harvard College refractor quickened and strengthened the current of prevalent opinion. It is now certain that the evidence furnished on both sides of the Atlantic as to the stellar composition of some conspicuous objects of this class, notably the Orion and "Dumb-bell" nebulæ, was delusive; but the spectroscope alone was capable of meeting it with a categorical denial. Meanwhile there seemed good ground for the persuasion, which now, for the last time, gained the upper hand, that nebulæ are, without exception, true "island universes," or assemblages of distant suns.—CLERKE *History of Astronomy*, pt. i, ch. 6, p. 147. (Bl., 1893.)

1060. ——— ——— *Astronomers Once Denied Satellites to Mars—Their Discovery by Persistent Search.*—We know now that this world [Mars] travels round the sun accompanied by two satellites. Their discovery was made in 1877, by Professor Asaph Hall, at the Observatory of Washington, by the aid of the most powerful telescope which existed at that time. It was not due to chance, like that of a great number of small planets and comets, but it was the result of a systematic search. Most astronomers were accustomed, like ordinary mortals, to read in the standard books the usual phrase, "Mars has no satellites"; however, some, doubting this assertion, continued to seek to surprise the secrets of Nature, which always keeps more than it allows us to grasp. They had already searched the neighborhood of Mars; but the instruments they used were much inferior to the equatorial of Washington, of which the object-glass measures no less than 66 centimeters (26 inches) in diameter, of which the focal length is 10 meters (32.8 feet), of which the optical power permits a magnification of 1,300 times, and which is moved by a mechanism of the greatest precision. By the aid of this excellent apparatus the eminent American astronomer undertook the attentive examination of the neighborhood of Mars from the beginning of the month of August, 1877, in order to observe assiduously this neighboring planet during the favorable epoch of its greatest proximity to the earth. After long evenings of barren expectation, he was about to abandon the search, when, encouraged by the entreaties of his wife, he persisted, and discovered a satellite during the night of the 11th, then a second on the night of the 17th.—FLAMMARION *Popular Astronomy*, bk. iv, ch. 4, p. 393. (A.)

1061. ——— ——— *Comets Styled "Visible Nothings"—Solidity of Meteorites—Nuclei of Comets.*—Ought we, then, to laugh at them [comets], and, with Sir John Herschel and Babinet, treat them as visible nothings? No; that would be the other extreme. Several comets seem to have solid nuclei. Solid bodies have already encountered the earth, have fallen on its surface, have killed men and set fire to houses. Most of the meteorites collected are, it is true, but small fragments of some few pounds in weight; but some have been met with which weigh several thousands of pounds. This is

not a question of principle, but only a relation of the little to the great. Now, bolides have been measured which have, so to say, grazed the earth, and which have been several miles in diameter. The nucleus of the comet of 1811 was 690 kilometers (428 miles) in diameter; that of the great comet of 1843 measured 8,000 kilometers (4,970 miles); that of the comet of 1858, 9,000 kilometers (5,580 miles); that of the comet of 1769 measured 44,000 kilometers (27,000 miles, 11,000 leagues) in diameter! Whatever may be the intrinsic nature of these nuclei, it is not doubtful that, if one of them were to encounter our globe in its passage, both moving with a velocity of more than 60,000 miles an hour, we should certainly perceive the shock.—FLAMMARION *Popular Astronomy*, bk. v, ch. 3, p. 529. (A.)

1062. ——— ——— *Emission Theory of Light—The Fallibility of Newton.*—Up to his demonstration of the composition of white light, Newton had been everywhere triumphant—triumphant in the heavens, triumphant on the earth—and his subsequent experimental work is, for the most part, of immortal value. But infallibility is not the property of man, and, soon after his discovery of the nature of white light, Newton proved himself human. He supposed that refraction and dispersion went hand in hand, and that you could not abolish the one without at the same time abolishing the other. Here Dollond corrected him. But Newton committed a graver error than this in deducing his emission theory of light, which he held to consist of material particles. . . . His experiments are imperishable, but his theory has passed away. For a century it stood like a dam across the course of discovery; but, like all barriers that rest upon authority, and not upon truth, the pressure from behind increased, and eventually swept the barrier away. This, as you know, was done mainly through the labors of Thomas Young, and his illustrious French fellow worker Fresnel.—TYNDALL *Lectures on Light*, lect. 6, p. 210. (A., 1898.)

1063. ——— ——— *Fall of Stones from the Sky Once Denied—Evidence Finally Accepted.*—A rather curious fact is that, altho the ancient traditions, the histories of antiquity and of the Middle Ages, and the popular beliefs had distinctly spoken of stones fallen from the sky, stones of the air, aerolites, the savants would not believe in them. Either they denied the fact itself, or they interpreted it quite otherwise, regarding the stones fallen on the earth as shot out by volcanic eruptions, raised from the ground by waterspouts, or even produced by certain condensations of matter in the midst of the atmosphere. In 1790 the illustrious Lavoisier, and in 1800 the whole Academy of Sciences, declared these facts to be absolutely apocryphal. In 1794 Chladni proved the extraterrestrial origin of these mysterious objects.

This almost general incredulity of the savants gave way when Biot read to the Academy of Sciences his report on the memorable fall which took place at Laigle, in the Department of the Orne, on April 26, 1803. After a minute inquiry made on the spot, the perfect accuracy of the circumstances related by public rumor of this very remarkable fall was verified. Numerous witnesses affirmed that some minutes after the appearance of a great bolide moving from southeast to northeast, and which had been perceived at Alençon, Caen, and Falaise, a fearful explosion, followed by detonations like the report of cannon and the fire of musketry, proceeded from an isolated black cloud in a very clear sky. A great number of meteoric stones were then precipitated on the surface of the ground, where they were collected, still smoking, over an extent of country which measured no less than seven miles in length. The largest of these stones weighed less than 10 kilograms (22 lbs.).—FLAMMARION *Popular Astronomy*, bk. v, ch. 4, p. 543. (A.)

1064. ——— ——— *False Results Confirming Each Other—The Sun's Distance.*—Dr. Matthew Stewart, Professor of Mathematics in the University of Edinburg, had made a futile attempt in 1763 to deduce the sun's distance from his disturbing power over our satellite. Tobias Mayer, of Göttingen, however, whose short career was so fruitful of suggestions, struck out the right way to the same end; and Laplace, in the seventh book of the "Mécanique Céleste," gave a solar parallax derived from the lunar "parallactic inequality" substantially identical with that issuing from Encke's subsequent discussion of the eighteenth-century transits. Thus two wholly independent methods—the trigonometrical, or method by survey, and the gravitational, or method by perturbation—seemed to corroborate each the upshot of the use of the other until the nineteenth century was well past its meridian. [It was refuted in 1854-58.] It is singular how often errors conspire to lead conviction astray.—CLERKE *History of Astronomy*, pt. ii, ch. 6, p. 284. (Bl., 1893.)

1065. ——— ——— *Herschel Recants His Earlier Views.*—I refer to the theory, which finds a place in all our text-books of astronomy, that the star-system has the form of a cloven flat disk. This theory was formed by Sir William Herschel when he was as yet unaware of the vastness and complexity of the star-system. The very words used in describing his process of research indicate that the great astronomer was full of confidence in the power of his great telescopes to fathom all the profundities of the sidereal system. He called his method star-gaging, he spoke of the distance at which the boundary of the star-system lay in this or that direction, and he discussed the numerical results he had obtained, without

doubting that those results really enabled him to determine the architecture of the galaxy.

But as the work progressed Sir William Herschel grew less confident. He began to recognize signs of a complexity of structure which set his method of star-gaging at defiance. It became more and more clear to him also, as he extended his survey, that the star-depths were in fact unfathomable—not only by his gaging telescope (commonly known as the twenty-feet reflector), but even by that mighty mirror which was one of the chief wonders of the world, until the great Rosse telescope dwarfed it into relative insignificance. At length Sir William Herschel definitely abandoned the principles on which his star-gaging had been based; and his observations, as well as his theoretical researches, were thenceforth directed to the determination of the general laws which prevail amid the star-depths.—PROCTOR *Our Place among Infinities*, p. 193. (L. G. & Co., 1897.)

1066. ——— ——— *Herschel's Conception of the Sun.*—A cool, dark, solid globe, its surface diversified with mountains and valleys, clothed in luxuriant vegetation, and "richly stored with inhabitants," protected by a heavy cloud-canopy from the intolerable glare of the upper luminous region, where the dazzling coruscations of a solar aurora some thousands of miles in depth evolved the stores of light and heat which vivify our world—such was the central luminary which Herschel constructed with his wonted ingenuity, and described with his wonted eloquence.—CLERKE *History of Astronomy*, pt. i, ch. 3, p. 65. (Bl., 1893.)

1067. ——— ——— *Liebig's Doctrine of Fermentation.*—Liebig insisted that all albuminoid bodies were unstable, and if left to themselves would fall to pieces—*i. e.*, ferment—without the aid of living organisms, or any initiative force greater than dead yeast-cells. It was at this juncture that Pasteur intervened to dispel the obscurities and contradictory theories which had been propounded.—NEWMAN *Bacteria*, ch. 4, p. 112. (G. P. P., 1899.)

1068. ——— ——— *Light Once Believed to Pass Instantly through Space—Newton's Error Regarding Refraction.*—By Römer's discovery, the notion entertained by Descartes, and espoused by Hooke, that light is propagated instantly through space, was overthrown. But the establishment of its motion through stellar space led to speculations regarding its velocity in transparent terrestrial substances. The index of refraction of a ray passing from air into water is $\frac{4}{3}$. Newton assumed these numbers to mean that the velocity of light in water being 4, its velocity in air is 3; and he deduced the phenomena of refraction from this assumption The reverse has since been proved to be the case—that is to say, the velocity of light in water being 3, its velocity in air is 4; but both in Newton's time and ours the same great principle determined, and determines, the course of light in all cases. In passing from point to point, whatever be the media in its path, or however it may be reflected, light takes the course which occupies least time.—TYNDALL *Lectures on Light*, lect. 1, p. 23. (A., 1898.)

1069. ——— ——— *Newton Held that Reflection and Refraction Could Not Be Separated—Dollond Proved the Contrary—The Achromatic Lens.*—Newton completed his proof [of the composite nature of white light] by synthesis in this way: The spectrum now before you is produced by a glass prism. Causing the decomposed beam to pass through a second similar prism, but so placed that the colors are refracted back and reblended, the perfectly white luminous disk is restored. In this case, refraction and dispersion are simultaneously abolished. Are they always so? Can we have the one without the other? It was Newton's conclusion that we could not. Here he erred, and his error, which he maintained to the end of his life, retarded the progress of optical discovery. Dollond subsequently proved that, by combining two different kinds of glass, the colors can be extinguished, still leaving a residue of refraction, and he employed this residue in the construction of achromatic lenses—lenses yielding no color—which Newton thought an impossibility.—TYNDALL *Lectures on Light*, lect. 1, p. 28. (A., 1898.)

1070. ——— ——— *Newton, Linnæus, Cuvier, Owen, Huxley, and Buffon.*—As Homer in the realm of poetry sometimes nods so there is hardly a man of science . . . who does not occasionally offer us some prosaic error. Thus Isaac Newton strangely boasted that he made no hypothesis, Linnæus classed together the walrus and the sloth, Cuvier fancied that from a fossil "foot" he could construct an extinct zoological "Hercules." Moreover, he strangely failed to understand the true affinities of the barnacle, nor were pouched beasts by any means correctly appreciated by him in spite of his zoological and anatomical genius. Our own "Prince of Anatomists," Owen, suffered ruefully from his failure to appreciate an ape's "Hippocampus Minor," while his vigorous opponent Huxley stood sponsor for that never-to-be-forgotten creature of the fancy, "Bathybius." Similarly, Buffon was led by his imagination to be at once unjust to Nature and to such a marvelous product of Nature as the sloth. [See ADAPTATION TO ENVIRONMENT—THE SLOTH.]—MIVART *Types of Animal Life*, ch. 9, p. 247. (L. B. & Co., 1893.)

1071. ——— ——— *Old Belief in Phlogiston—"Imponderable Agents."*—For years after Newton, the chemists believed universally in a kind of matter called phlogiston, which not only could be removed from a sub-

stance without diminishing its weight, but whose subtraction actually added to the weight. It is the great merit of Lavoisier that he . . . was the first to see clearly that, in every chemical process, increase of weight means increase of material, and loss of weight loss of material. Iron, in rusting, gains in weight. Hence, said Lavoisier, it has combined with some material. No, said the defenders of the phlogiston theory—such men as Cavendish, Priestly, and Scheele—it has only lost phlogiston. You are making too much of this matter of weight. Phlogiston differs from your gross forms of matter in that it is specifically light, and, when taken from a body, increases its weight. We smile at this idea, and we find it difficult to believe that these men, the first scientific minds of their age, could believe in such absurdity. But we must remember that the idea did not originate with them. It was a part of the old Greek philosophy, and from the pages of Aristotle was taught in every school of Europe until within two hundred years; and, even in our own time, we still hear of imponderable agents. Text-books of science are used in some of our schools which refer the phenomena of heat and electricity to attenuated forms of matter, that can be added to or subtracted from bodies without altering their weight. Such facts should teach us, not that we are so much wiser than our fathers, but that our familiar ideas of the composition of matter are not such simple deductions from the phenomena of Nature as they appear to us; and this discussion of the evidence, on which these conclusions are based, is therefore by no means superfluous.—COOKE *New Chemistry*, lect. 5, p. 112. (A., 1899.)

1072. ——— ——— *The Imagined "Phlogiston," the Principle of Fire.*—They [ancient philosophers] termed the principle of fire phlogiston, and burning, or the escape of fire, dephlogistication, and their ingenious system did not a little to retard the progress of truth. The philosophers of that age either took no account of the increase of weight which results from burning, or attempted to explain the few instances in which the fact was forced upon their attention by the fanciful notion of Aristotle—that the essence of fire was specifically light. Hence, they reasoned, phlogiston buoys up all bodies into which it enters, and after its escape in the process of burning, the burnt material must weigh more than before. It was not until 1783 that the true theory of combustion was discovered, and from this discovery modern chemistry dates. The fortunate discoverer was Lavoisier. He proved, by simply weighing the products of combustion, that burning, instead of being a loss of phlogiston, is a union of the burning substance with the oxygen of the air, and this theory is now one of the best established principles of science.—COOKE *Religion and Chemistry*, ch. 3, p. 78. (A., 1897.)

1073. ——— ——— *Theories Abandoned by Sir William Herschel—Change upon Evidence—Honest Avowal of the Change—The True Scientist Seeks Fact and Truth.*—[Herschel] wrote thus in 1802, seventeen years after he had enunciated the cloven-disk theory [which regards the sidereal universe as a cloven disk, which we look through edgewise in the Milky Way]: "Altho our sun and all the stars we see may truly be said to be in the plane of the Milky Way, yet I am now convinced by a long inspection and continued examination of it, that the Milky Way itself consists of stars very differently scattered from those which are immediately about us." And again in 1811 he said: "When the novelty of the subject is considered, we cannot be surprised that many things formerly taken for granted should, on examination, prove to be different from what they were generally, but incautiously, supposed to be. For instance, an equal scattering of the stars may be admitted in certain calculations; but when we examine the Milky Way, or the closely compressed clusters of stars, this supposed equality of scattering must be given up."—PROCTOR *Expanse of Heaven*, p. 260. (L. G. & Co., 1897.)

1074. ——— ——— *Theory Not a Safe Guide for Vital Processes—Bone-soup of French Academy.*—There are other juices besides the albumin; these are the most important of the flavoring constituents, and, with the other constituents of animal food, have great nutritive value; so much so that animal food is quite tasteless and almost worthless without them. I have laid especial emphasis on the above qualification, lest the reader should be led into an error originated by the bone-soup committee of the French Academy, and propagated widely by Liebig—that of regarding these juices as a concentrated nutriment when taken alone. They constitute collectively the *extractum carnis*, which, with the addition of more or less gelatin (the less the better), is commonly sold as Liebig's "Extract of Meat." It is prepared by simply mincing lean meat, exposing it to the action of cold water, and then evaporating down the solution of extract thus obtained.—WILLIAMS *Chemistry of Cookery*, ch. 3, p. 25. (A., 1900.)

1075. ——— ——— *The Theory of Catastrophism in Geology.*—Cuvier imagined that the whole history of the earth's crust, since the time when living creatures had first appeared on the surface, must be divided into a number of perfectly distinct periods, or divisions of time, and that the individual periods must have been separated from one another by peculiar revolutions of an unknown nature (cataclysms, or catastrophes). Each revolution was followed by the utter annihilation of the till then existing animals and plants, and after its termination a completely new creation of organic forms took place. A new world of

animals and plants, absolutely and specifically distinct from those of the preceding historical periods, was called into existence at once, and now again peopled the globe for thousands of years, till it again was suddenly destroyed in the crash of a new revolution.—HAECKEL *History of Creation*, vol. i, ch. 3, p. 60. (K. P. & Co., 1899.)

1076. ——— ——— *The Will Once Deemed a Separate Faculty.*—All our deeds were considered by the early psychologists to be due to a peculiar faculty called the will, without whose fiat action could not occur. Thoughts and impressions, being intrinsically inactive, were supposed to produce conduct only through the intermediation of this superior agent. Until they twitched its coat-tails, so to speak, no outward behavior could occur. This doctrine was long ago exploded by the discovery of the phenomena of reflex action, in which sensible impressions, as you know, produce movement immediately and of themselves.—JAMES *Talks to Teachers*, ch. 15, p. 170. (H. H. & Co., 1900.)

1077. ——— ——— *Volcanic Confused with Sedimentary Rocks.*—Thus on the shore near Portrush, in the North of Ireland, and in the skerries which lie off that coast, there occur great rock-masses, some of which undoubtedly agree with basalt in all their characters, while others are dark colored and crystalline, and are frequently crowded with *Ammonites* and other fossils. We now know that the explanation of these facts is as follows: Near where the town of Portrush is now situated, a volcanic vent was opened in Miocene times through rocks of Lias shale. From this igneous center, sheets and dikes of basaltic lava were given off, and in consequence of their contact with these masses of lava, the Lias shales were baked and altered, and assumed a crystalline character, tho the traces of the fossils contained in them were not altogether obliterated. In the last century the methods which had been devised for the discrimination of rocks were so imperfect that no distinction was recognized between the true basalt and the altered shale, and specimens of the latter containing *Ammonites* found their way to almost every museum in Europe, and were used as illustrations of the "origin of basalt by aqueous precipitation."—JUDD *Volcanoes*, ch. 9, p. 249. (A., 1899.)

1078. ——— ——— *Wild Conjecture of Sir John Herschel—Supposed Living Creatures on the Sun.*—We must remember how much there is unknown in the sun still, and what a great mystery even yet overhangs many of our relations to that body which maintains our own vital action, when we read the following words, which are [Sir John] Herschel's own. Speaking of these supposed spindle-shaped monsters [shown in certain drawings of the sun's surface], he says:

"The exceedingly definite shape of these objects, their exact similarity to one another, and the way in which they lie across and athwart each other—all these characters seem quite repugnant to the notion of their being of a vaporous, a cloudy, or a fluid nature. Nothing remains but to consider them as separate and independent sheets, flakes, or scales, having some sort of solidity. And these . . . are evidently the immediate sources of the solar light and heat, by whatever mechanism or whatever processes they may be enabled to develop, and as it were elaborate, these elements from the bosom of the non-luminous fluid in which they appear to float. Looked at in this point of view, we cannot refuse to regard them as organisms of some peculiar and amazing kind; and tho it would be too daring to speak of such organization as partaking of the nature of life, yet we do know that vital action is competent to develop at once heat and light and electricity."

Such are his words; and when we consider that each of these solar inhabitants was supposed to extend about two hundred by one thousand miles upon the surface of the fiery ocean, we may subscribe to Mr. Proctor's comment, that "Milton's picture of him who on the fires of hell 'lay floating many a rood,' seems tame and commonplace compared with Herschel's conception of these floating monsters, the least covering a greater space than the British Islands."—LANGLEY *New Astronomy*, ch. 13, p. 14. (H. M. & Co., 1896.)

1079. ERUPTION OF MONTE NUOVO —*Fish Taken on Land—Birds Falling Dead.*—Sir William Hamilton has given us two original letters describing this eruption [by which Monte Nuovo was formed]. The first, by Falconi, dated 1538, contains the following passages: "It is now two years since there have been frequent earthquakes at Puzzuoli, Naples, and the neighboring parts. On the day and in the night before the eruption (of Monte Nuovo), about twenty shocks, great and small, were felt. The eruption began on the 29th of September, 1538. It was on a Sunday, about one o'clock in the night, when flames of fire were seen between the hot baths and Tripergola. In a short time the fire increased to such a degree that it burst open the earth in this place, and threw up so great a quantity of ashes and pumice-stones, mixed with water, as covered the whole country. The next morning (after the formation of Monte Nuovo) the poor inhabitants of Puzzuoli quitted their habitations in terror, covered with the muddy and black shower which continued the whole day in that country—flying from death, but with death painted in their countenances. Some with their children in their arms, some with sacks full of their goods; others leading an ass, loaded with their frightened family, towards Naples; others carrying quantities of birds, of various sorts, that had fallen dead at the beginning of the eruption; oth-

ers, again, with fish which they had found, and which were to be met with in plenty on the shore, the sea having left them dry for a considerable time. I accompanied Signor Moramaldo to behold the wonderful effects of the eruption. The sea had retired on the side of Baiæ, abandoning a considerable tract, and the shore appeared almost entirely dry, from the quantity of ashes and broken pumice-stones thrown up by the eruption. I saw two springs in the newly discovered ruins; one before the house that was the queen's, of hot and salt water," etc. —LYELL *Principles of Geology*, bk. ii, ch. 23, p. 367. (A., 1854.)

1080. ERUPTION OF VESUVIUS— —*Description by Pliny.*—The first symptom of the revival of the energies of this volcano [Vesuvius] was the occurrence of an earthquake in the year 63 after Christ, which did considerable injury to the cities in its vicinity. From that time to the year 79 slight shocks were frequent; and in the month of August of that year they became numerous and violent, till they ended at length in an eruption. The elder Pliny, who commanded the Roman fleet, was then stationed at Misenum; and in his anxiety to obtain a near view of the phenomena, he lost his life, being suffocated by sulfurous vapors. His nephew, the younger Pliny, remained at Misenum, and has given us, in his "Letters," a lively description of the awful scene. A dense column of vapor was first seen rising vertically from Vesuvius, and then spreading itself out laterally, so that its upper portion resembled the head and its lower the trunk of the pine, which characterizes the Italian landscape. This black cloud was pierced occasionally by flashes of fire, as vivid as lightning, succeeded by darkness more profound than night. Ashes fell even upon the ships at Misenum, and caused a shoal in one part of the sea—the ground rocked, and the sea receded from the shores, so that many marine animals were seen on the dry sand. The appearances above described agree perfectly with those witnessed in more recent eruptions, especially those of Monte Nuovo, in 1538, and of Vesuvius in 1822.—LYELL *Principles of Geology*, bk. ii, ch. 23, p. 363. (A., 1854.)

1081. ——— ——— *Rain of Ashes—Darkness at Midday.*—Twenty-four hours after the fall of the cone of scoriæ [of Vesuvius, in the eruption of 1822], which was 426 feet high, and when the small but numerous streams of lava had flowed off, on the night between the 23d and 24th of October, there began a fiery eruption of ashes and rapilli, which continued uninterruptedly for twelve days, but was most violent during the first four days. During this period the explosions in the interior of the volcano were so loud that the mere vibrations of the air caused the ceilings to crack in the palace of Portici, altho no shocks of an earthquake were then or had previously been experienced. A remarkable phenomenon was observed in the neighboring villages of Resina, Torre del Greco, Torre del' Annunziata, and Bosche Tre Case. Here the atmosphere was so completely saturated with ashes that the whole region was enveloped in complete darkness during many hours in the middle of the day. The inhabitants were obliged to carry lanterns with them through the streets, as is often done in Quito during the eruptions of Pichincha. Never had the flight of the inhabitants been more general, for lava streams are less dreaded even than an eruption of ashes, a phenomenon unknown here in any degree of intensity, and one which fills the imaginations of men with images of terror from the vague tradition of the manner in which Herculaneum, Pompeii, and Stabiæ were destroyed.—HUMBOLDT *Views of Nature*, p. 365. (Bell, 1896.)

1082. ETERNITY, SUGGESTION OF —*Approach and Departure of a Comet—Whence and Whither—To Us a Journey of Perhaps Eight Million Years.*—A comet is seen in the far distant depths of space as a faint and scarcely discernible speck. It draws nearer and nearer with continually increasing velocity, growing continually larger and brighter. Faster and faster it rushes on, until it makes its nearest approach to our sun, and then, sweeping around him, it begins its long return voyage into infinite space. As it recedes it grows fainter and fainter, until at length it passes beyond the range of the most powerful telescopes made by man, and is seen no more. It has been seen for the first and last time by the generation of men to whom it has displayed its glories. It has been seen for the first and last time by the race of man itself. Nay more, according to the calculations made by astronomers, the comet has made its first and last visit to the solar system. Of all comets this cannot, indeed, be affirmed: but there are some whose motions will bear no other interpretation.

Whence came the comet? Trace back its path, and we find no place from which it could have started on its course until we consider the stars in the region of the heavens whence the comet appeared to travel. It would be idle to select any star in particular in that region as probably marking the spot whence the comet started. But suppose we take the brightest, some leading orb, lying at a distance not absolutely unmeasurable by man; suppose even that the course of that comet as it approached was such that it might have come from the star Alpha Centauri, which, so far as is known, is the nearest of all in the heavens; then, at a moderate computation, the journey from the neighborhood of that star has not occupied less than eight million years.—PROCTOR *Expanse of Heaven*, p. 134. (L. G. & Co., 1897.)

1083. ETHER PERVADES ALL BODIES—*Transparency to Different Colors—Union of Transparent Substances Producing Darkness.*—The luminiferous ether fills stellar space; it makes the universe a whole, and renders possible the intercommunication of light and energy between star and star. But the subtle substance penetrates farther; it surrounds the very atoms of solid and liquid substances. Transparent bodies are those which are so related to the ether that the waves of light can pass through them without transference of motion to their atoms. In colored bodies, certain waves are absorbed; but those which give the body its color pass without absorption. Through a solution of sulfate of copper, for example, the blue waves speed unimpeded, while the red waves are destroyed. When a luminous beam is sent through this solution, the red end of its spectrum is cut away. Red glass, on the contrary, owes its color to the fact that its substance can be traversed freely by the longer undulations of red, while the shorter waves are absorbed. Placed in the path of the light, it leaves merely a vivid red band upon the screen. The blue liquid, then, cuts off the rays transmitted by the red glass; and the red glass cuts off those transmitted by the liquid; by the union of both we ought to have perfect opacity, and so we have. When both are placed in the path of the beam, the entire spectrum disappears; the union of the two partially transparent bodies producing an opacity equal to that of pitch or metal.—TYNDALL *Heat a Mode of Motion*, lect. 11, p. 304. (A., 1900.)

1084. ETHER PERVADING SPACE A DOCTRINE OF ANCIENT PHILOSOPHY—*Held by Ionic Philosophers To Be Self-luminous.*—In the dogmas of the Ionic philosophy of Anaxagoras and Empedocles, this ether differed wholly from the actual (denser) vapor-charged air which surrounds the earth, and "probably extends as far as the moon." It was of "a fiery nature, a brightly beaming, pure fire-air, of great subtlety and eternal serenity."

Considered as a medium filling the regions of space, the ether of Empedocles presents no other analogies excepting those of subtlety and tenuity with the ether, by whose transverse vibrations modern physicists have succeeded so happily in explaining, on purely mathematical principles, the propagation of light, with all its properties of double refraction, polarization, and interference. The natural philosophy of Aristotle further teaches that the ethereal substance penetrates all the living organisms of the earth —both plants and animals; that it becomes in these the principle of vital heat, the very germ of a psychical principle, which, uninfluenced by the body, stimulates men to independent activity. These visionary opinions draw down ether from the higher regions of space to the terrestrial sphere, and represent it as a highly rarefied substance constantly penetrating through the atmosphere and through solid bodies; precisely similar to the vibrating light-ether of Huygens, Hooke, and modern physicists. But what especially distinguishes the older Ionic from the modern hypothesis of ether is the original assumption of luminosity, a view, however, not entirely advocated by Aristotle. The upper fire-air of Empedocles is expressly termed brightly radiating and is said to be seen by the inhabitants of the earth in certain phenomena, gleaming brightly through fissures and chasms which occur in the firmament.—HUMBOLDT *Cosmos*, vol. iii, p. 32. (H., 1897.)

1085. ETHICS UNIVERSALLY ASSOCIATED WITH RELIGION—*Religion an Everlasting Reality.*—Universally since that [primeval] time the notion of ethics has been inseparably associated with the notion of religion, and the sanction for ethics has been held to be closely related with the world beyond phenomena. There are philosophers who maintain that with the further progress of enlightenment this close relation will cease to be asserted, that ethics will be divorced from religion, and that the groping of the human soul after its God will be condemned as a mere survival from the errors of primitive savagery, a vain and idle reaching out toward a world of mere phantoms. I mention this opinion merely to express unqualified and total dissent from it. I believe it can be shown that one of the strongest implications of the doctrine of evolution is the everlasting reality of religion.—FISKE *Through Nature to God*, pt. ii, ch. 9, p. 110. (H. M. & Co., 1900.)

1086. EVIDENCE MULTIPLIES FOR WILLING MINDS—*Fall of Meteorites in France Attested by Academicians—Then Abundant Instances the World Over.*—Stories of falling stones, then, kept arising from time to time during the last century as they had always done, and philosophers kept on disbelieving them as they had always done, till an event occurred which suddenly changed scientific opinion to compulsory belief.

On the 26th of April, 1803, there fell, not in some far-off part of the world, but in France, not one alone, but many thousand stones, over an area of some miles, accompanied with noises like the discharge of artillery. A committee of scientific men visited the spot on the part of the French Institute, and brought back not only the testimony of scores of witnesses or auditors, but the stones themselves. Soon after stones fell in Connecticut, and here and elsewhere, as soon as men were prepared to believe, they found evidence multiplied: and such falls, it is now admitted, tho rare in any single district, are of what may be called frequent occurrence as regards the world at large—for, taking land and sea together, the annual stone-falls are probably to be counted by hundreds.—LANGLEY *New Astronomy*, ch. 6, p. 186. (H. M. & Co., 1896.)

1087. EVIDENCE OF PHOSPHORESCENCE IN DEEP-SEA ANIMALS—The subject of the power of emitting phosphorescent light possessed by some deep-sea animals is much more difficult to deal with.

The presence of distinct organs in many of the deep-sea fish that can only be reasonably interpreted as phosphorescent organs, the presence of well-developed and evidently functional eyes in many deep-sea animals, and many other considerations render it very highly probable that some, if not many, forms emit a phosphorescent light.

The power and constancy of the light emitted, however, must for the present remain a matter of conjecture.—HICKSON *Fauna of the Deep Sea*, ch. 4, p. 75. (A., 1894.)

1088. EVIDENCE OF SELF-DETERMINING POWER — *Common-sense Proof of External World.*—The writer entirely agrees with Archbishop Manning, in maintaining that we have exactly the same evidence of the existence of this self-determining power within ourselves, that we have of the existence of a material world outside ourselves. For however intimate may be the functional correlation between mind and brain—and Archbishop Manning seems disposed to go as far as the writer in recognizing this intimacy—"there is still another faculty, and more than this, another agent, distinct from the thinking brain." . . . "That we are conscious of thought and will, is a fact of our internal experience. It is a fact also of the universal experience of all men; this is an immediate and intuitive truth of absolute certainty. Dr. Carpenter lays down as an axiomatic truth 'that the common-sense decision of mankind, in regard to the existence of an external world, is practically worth more than all the arguments of all the logicians who have discussed the basis of our belief in it.'"—CARPENTER *Mental Physiology*, bk. i, ch. 1, p. 5. (A., 1900.)

1089. EVIDENCE THAT CHALK IS AN ANCIENT SEA-BOTTOM—The evidence furnished by the hewing, facing, and superposition of the stones of the pyramids, that these structures were built by men, has no greater weight than the evidence that the chalk was built by *Globigerinæ;* and the belief that those ancient pyramid-builders were terrestrial and air-breathing creatures, like ourselves, is not better based than the conviction that the chalk-makers lived in the sea. But as our belief in the building of the pyramids by men is not only grounded on the internal evidence afforded by these structures, but gathers strength from multitudinous collateral proofs, and is clinched by the total absence of any reason for a contrary belief; so the evidence drawn from the *Globigerinæ*, that the chalk is an ancient sea-bottom, is fortified by innumerable independent lines of evidence; and our belief in the truth of the conclusion to which all positive testimony tends, receives the like negative justification from the fact that no other hypothesis has a shadow of foundation.—HUXLEY *Lay Sermons*, serm. 9, p. 187. (G. P. P., 1897.)

1090. EVIDENCE, UNTRUSTWORTHY—*Excitement, Credulity, and Inaccuracy May Vitiate.*—But, in dealing with the descriptions of these grand and terrible events, we must always be on our guard against accepting as literal facts the statements made by witnesses, often writing at some distance from the scene of action, and almost always under the influence of violent excitement and terror. The desire to administer to the universal love of the marvelous, and the tendency to exaggeration, will usually account for many of the wonderful statements contained in such records; and, even where the witness is accurately relating events which he thinks passed before his eyes, we must remember that it is probable he may have had neither the opportunity nor the capacity for exact observation.—JUDD *Volcanoes*, ch. 2, p. 30. (A., 1899.)

1091. EVIL DESTROYED BY GROWTH OF GOOD—*Scientific Control of Bacteria—Favorable Germs Planted to Exterminate the Undesirable.*—Recently, however, a new method has been introduced, largely through the work and influence of Professor Storch in Denmark, which is based upon our new knowledge respecting bacterial action in cream-ripening. We refer to the artificial processes of ripening set up by the addition of pure cultures of favorable germs. If a culture of organisms possessing the faculty of producing in cream a good flavor be added to the sweet cream, it is clear that advantage will accrue. This simple plan of starting any special or desired flavor by introducing the specific micro-organisms of that flavor may be adopted in two or three different ways. If cream be inoculated with a large, pure culture of some particular kind of bacteria, this species will frequently grow so well and so rapidly that it will check the growth of the other bacteria which were present in the cream at the commencement and before the starter was added. That is, perhaps, the simplest method of adding an artificial culture.—NEWMAN *Bacteria*, ch. 6, p. 217. (G. P. P., 1899.)

1092. EVIL, MORAL, A UNIVERSAL FACT—*Unworthiness Distinct from Ignorance.*—There is an absolute contrast between our sense of limitation in respect to intellectual power (or knowledge) and our sense of unworthiness in respect to moral character. It is not of ignorance, but of knowledge, that we are conscious here—even the knowledge of the distinction between good and evil, and of that special sense which in our nature is associated with it, namely, the sense of moral obligation. Now it is a universal fact of consciousness as regards ourselves, and of observation in regard to others, that, knowing evil to be evil, men are nevertheless

prone to do it, and that, having this sense of moral obligation, they are nevertheless prone to disobey it. This fact is entirely independent of the particular standard by which men in different stages of society have judged certain things to be good and other things to be evil. It is entirely independent of the infinite variety of rules according to which they recognize the doing of particular acts, and the abstention from other acts, to be obligatory upon them. Under every variety of circumstance in regard to these rules, under every diversity of custom, of law, or of religion by which they are stablished, the general fact remains the same—that what men themselves recognize as duty they continually disobey, and what according to their own standard they acknowledge to be wrong they continually do. —ARGYLL *Unity of Nature*, ch. 9, p. 190. (Burt.)

1093. EVIL OVERCOME BY GOOD —*Inhibition by Substitution—Love of Right the Highest Victory (Jer. xxxi, 33).*—It is clear that in general we ought, whenever we can, to employ the method of inhibition by substitution. He whose life is based upon the word "no," who tells the truth because a lie is wicked, and who has constantly to grapple with his envious and cowardly and mean propensities, is in an inferior situation in every respect to what he would be if the love of truth and magnanimity positively possessed him from the outset, and he felt no inferior temptations.—JAMES *Talks to Teachers*, ch. 15, p. 194. (H. H. & Co., 1900.)

1094. EVOLUTION A GENERAL LAW —*Recognized in Diverse Realms of Being.*—The interpretation of phenomena as results of evolution has been independently showing itself in various fields of inquiry, quite remote from one another. The supposition that the solar system has been evolved out of diffused matter is a supposition wholly astronomical in its origin and application. Geologists, without being led thereto by astronomical considerations, have been step by step advancing towards the conviction that the earth has reached its present varied structure by modification upon modification. The inquiries of biologists have proved the falsity of the once general belief, that the germ of each organism is a minute repetition of the mature organism, differing from it only in bulk; and they have shown, contrariwise, that every organism advances from simplicity to complexity through insensible changes. Among philosophical politicians there has been spreading the perception that the progress of society is an evolution: the truth that "constitutions are not made, but grow," is seen to be a part of the more general truth that societies are not made, but grow. It is now universally admitted by philologists that languages, instead of being artificially or supernaturally formed, have been developed. And the histories of religion, of science, of the fine arts, of the industrial arts, show that these have passed through stages as unobtrusive as those through which the mind of a child passes on its way to maturity.—SPENCER *Biology*, pt. iii, ch. 3, p. 432. (A., 1900.)

1095. EVOLUTION A STUDY FOR THE NURSERY—*Every Mother an Unconscious Evolutionist—The Evolution of Man Read in the Mind of a Little Child.*—The most beautiful witness to the evolution of man is the mind of a little child. The stealing in of that inexplicable light—yet not more light than sound or touch—called consciousness, the first flicker of memory, the gradual governance of will, the silent ascendancy of reason—these are studies in evolution the oldest, the sweetest, and the most full of meaning for mankind. Evolution, after all, is a study for the nursery. It was ages before Darwin or Lamarck or Lucretius that maternity, bending over the hollowed cradle in the forest for a first smile of recognition from her babe, expressed the earliest trust in the doctrine of development. Every mother since then is an unconscious evolutionist, and every little child a living witness to ascent.—DRUMMOND *Ascent of Man*, ch. 4, p. 119. (J. P., 1900.)

1096. EVOLUTION CHANGES ITS COURSE—*From a Physical to a Psychical Universe.*—Once it was a physical universe, now it is a psychical universe. And to say that the working of evolution has changed its course, and set its compass in psychical directions, is to call attention to the most remarkable fact in Nature. Nothing so original or so revolutionary has ever been given to science to discover, to ponder, or to proclaim. The power of this event to strike and rouse the mind will depend upon one's sense of what the working of evolution has been to the world; but those who realize this even dimly will see that no emphasis of language can exaggerate its significance.—DRUMMOND *Ascent of Man*, ch. 3, p. 117. (J. P., 1900.)

1097. EVOLUTION CONSISTENT WITH CREATION—But of this we may be sure, that if men should indeed ultimately become convinced that species have been all born just as individuals are now all born, and that such has been the universal method of creation, this conviction will not only be found to be soluble, so to speak, in the old beliefs respecting a creative mind, but it will be unintelligible and inconceivable without them, so that men, in describing the history and aim and direction of evolution, will be compelled to use substantially the same language in which they have hitherto spoken of the history of creation.—ARGYLL *Unity of Nature*, ch. 8, p. 173. (Burt.)

1098. EVOLUTION EXALTS HUMANITY—*Man the Last Victor of Ages of Struggle—The Fruit and Crown of a Past Eternity.*—Science is charged, be it once

more recalled, with numbering man among the beasts, and leveling his body with the dust. But he who reads for himself the history of creation as it is written by the hand of evolution will be overwhelmed by the glory and honor heaped upon this creature. To be a man, and to have no conceivable successor; to be the fruit and crown of the long past eternity, and the highest possible fruit and crown: to be the last victor among the decimated phalanxes of earlier existences, and to be nevermore defeated; to be the best that Nature in her strength and opulence can produce; to be the first of that new order of beings who, by their dominion over the lower world and their equipment for a higher, reveal that they are made in the image of God—to be this is to be elevated to a rank in Nature more exalted than any philosophy or any poetry or any theology has ever given to man.—DRUMMOND *Ascent of Man*, ch. 3, p. 115. (J. P., 1900.)

1099. EVOLUTION INTERPRETED AS BLANK MATERIALISM—Modern scientific thought is called upon to decide between this hypothesis [of evolution] and another; and public thought generally will afterwards be called upon to do the same. But, however the convictions of individuals here and there may be influenced, the process must be slow and secular which commends the hypothesis of natural evolution to the public mind. For what are the core and essence of this hypothesis? Strip it naked, and you stand face to face with the notion that not alone the more ignoble forms of animalcular or animal life, not alone the nobler forms of the horse and lion, not alone the exquisite and wonderful mechanism of the human body, but that the human mind itself—emotion, intellect, will, and all their phenomena—were once latent in a fiery cloud. Surely the mere statement of such a notion is more than a refutation. But the hypothesis would probably go even farther than this. Many who hold it would probably assent to the position that, at the present moment, all our philosophy, all our poetry, all our science, and all our art—Plato, Shakespeare, Newton, and Raphael—are potential in the fires of the sun. We long to learn something of our origin. If the evolution hypothesis be correct, even this unsatisfied yearning must have come to us across the ages which separate the primeval mist from the consciousness of to-day. I do not think that any holder of the evolution hypothesis would say that I overrate or overstrain it in any way. I merely strip it of all vagueness, and bring before you, unclothed and unvarnished, the notions by which it must stand or fall.—TYNDALL *Fragments of Science*, vol. ii. ch. 8, p. 130. (A., 1897.)

1100. EVOLUTION INVOLVES MORE THAN NATURAL SELECTION—*Morality Rooted in the Foundations of the Universe.*—In such a universe [controlled solely by the struggle for life and survival of the fittest] we may look in vain for any sanction for morality, any justification for love and self-sacrifice; we find no hope in it, no consolation; there is not even dignity in it, nothing whatever but resistless all-producing and all-consuming energy. Such a universe, however, is not the one in which we live. In the cosmic process of evolution, whereof our individual lives are part and parcel, there are other agencies at work besides natural selection, and the story of the struggle for existence is far from being the whole story. I think it can be shown that the principles of morality have their roots in the deepest foundations of the universe, that the cosmic process is ethical in the profoundest sense, that in that far-off morning of the world when the stars sang together and the sons of God shouted for joy, the beauty of self-sacrifice and disinterested love formed the chief burden of the mighty theme.—FISKE *Through Nature to God*, pt. ii, ch. 4, p. 78. (H. M. & Co., 1900.)

1101. EVOLUTION, MAN KNOWS THAT IT IS A PROCESS—*Intelligently Co-operates with It.*—Man differs from every other product of the evolutionary process in being able to see that it is a process, in sharing and rejoicing in its unity, and in voluntarily working through the process himself. If he is part of it he is also more than part of it, since he is at once its spectator, its director, and its critic.—DRUMMOND *Ascent of Man*, p. 12. (J. P., 1900.)

1102. EVOLUTION, MATERIALISTIC—*A Pillar without a Capital—A Process without a Purpose—Christianity Supplies the Goal.*—Hitherto evolution had no future. It was a pillar with marvelous carving, growing richer and finer towards the top, but without a capital; a pyramid, the vast base buried in the inorganic, towering higher and higher, tier above tier, life above life, mind above mind, ever more perfect in its workmanship, more noble in its symmetry, and yet withal so much the more mysterious in its aspiration. The most curious eye, following it upwards, saw nothing. The cloud fell and covered it. Just what men wanted to see was hid. The work of the ages had no apex. But the work begun by Nature is finished by the Supernatural — as we are wont to call the higher natural. And as the veil is lifted by Christianity it strikes men dumb with wonder. For the goal of evolution is Jesus Christ.—DRUMMOND *Natural Law in the Spiritual World*, essay 8, p. 280. (H. Al.)

1103. EVOLUTION NOT ACCOUNTED FOR—To give an account of evolution, it need scarcely be remarked, is not to account for it. No living thinker has yet found it possible to account for evolution.—DRUMMOND *Ascent of Man*, int., p. 4. (J. P., 1900.)

1104. EVOLUTION NOT ATHEISTIC *—Design Not Superseded—Place of Second Causes.*—To myself the conception of a continuity of action which required no departure to meet special contingencies, because the plan was all-perfect in the beginning, is a far higher and nobler one than that of a succession of interruptions, such as would be involved in the creation *de novo* of the vast series of new types which paleontological study is daily bringing to our knowledge. And in describing the process of evolution in the ordinary language of science, as due to "secondary causes," we no more dispense with a First Cause than we do when we speak of those physical forces which, from the theistic point of view, are so many diverse modes of manifestation of one and the same power. Nor do we in the least set aside the idea of an original design when we regard these adaptations, which are commonly attributed to special exertions of contriving power and wisdom, as the outcome of an all-comprehensive intelligence which foresaw that the product would be "good," before calling into existence the germ from which it would be evolved. We simply, to use the language of Whewell, "transfer the notion of design and end from the region of facts to that of laws," that is, from the particular cases to the general plan: and find ourselves aided in our conception of the infinity of creative wisdom and power, when we regard it as exerted in a manner which shows that not only the peopling of the globe with the plants and animals suited to every phase of its physical conditions, but the final production of man himself—the heir of all preceding ages, with capacities that enable him to become but "a little lower than the angels"—was comprehended in the original scheme.—CARPENTER *Nature and Man,* lect. 14, p. 407. (A., 1889.)

1105. EVOLUTION OF EARTH'S CRUST—*Theory of Catastrophe Abandoned—Past Flows Gradually into Present.*—With increased knowledge . . . it was recognized that no hard-and-fast line separates past and present. The belief in world-wide, or nearly world-wide, catastrophes disappeared. Geologists came to see that the fashioning of the earth's surface had been going on for a long time, and is still in progress. The law of evolution, they have found, holds true for the crust of the globe just as it does for the myriad tribes of plants and animals that clothe and people it. It is no longer doubted that the existing configuration of the land has resulted from the action of forces that are still in operation, and by observation and reasoning the history of the various phases in the evolution of surface-features can be unfolded.—GEIKIE *Earth Sculpture,* ch. 1, p. 2. (G. P. P., 1898.)

1106. EVOLUTION OF EVIL—*The Law of Degeneracy—Double Aspect of Development.*—It is a curious misunderstanding of what that law [of evolution] really is to suppose that it leads only in one direction. It leads in every direction in which there is at work any one of the "potential energies" of Nature. Development is the growth of germs, and according to the nature of the germ so is the nature of the growth. The flowers and fruits which minister to the use of man have each their own seed, and so have the briers and thorns which choke them. Evil has its germs as well as good, and the evolution of them is accompanied by effects to which it is impossible to assign a limit. Movement is the condition of all being, in moral as well as in material things. Just as one thing leads to another in knowledge and in virtue, so does one thing lead to another in ignorance and vice. Those gradual processes of change which arise out of action and reaction between the external condition and the internal nature of man have an energy in them of infinite complexity and power. We stand here on the firm ground of observation and experience. In the shortest space of time, far within the limits even of a single life, we are accustomed to see such processes effectual both to elevate and degrade. The weak become weaker and the bad become worse. "To him that hath more is given, and from him that hath not is taken even that which he seemeth to have." And this law, in the region of character and of morals, is but the counterpart of the law which prevails in the physical regions of Nature, where also development has its double aspect. It cannot bring one organism to the top without sinking another organism to the bottom. That vast variety of natural causes which have been grouped and almost personified under the phrase "natural selection" are causes which necessarily include both favorable and unfavorable conditions. Natural rejection, therefore, is the inseparable correlative of natural selection.—ARGYLL *Unity of Nature,* ch. 10, p. 230. (Burt.)

1107. EVOLUTION OF EVOLUTION *—By Its Very Nature a System of Progress.* —This is the age of the evolution of evolution. All thoughts that the evolutionist works with, all theories and generalizations, have been themselves evolved and are now being evolved. Even were his theory perfected, its first lesson would be that it was itself but a phase of the evolution of further opinion, no more fixed than a species, no more final than the theory which it displaced. Of all men the evolutionist, by the very nature of his calling, the mere tools of his craft, his understanding of his hourly shifting-place in this always moving and ever more mysterious world, must be humble, tolerant, and undogmatic.—DRUMMOND *Ascent of Man,* int., p. 7. (J. P., 1900.)

1108. EVOLUTION OF LANGUAGE TAUGHT BY COMPARATIVE PHILOLOGY—*Renan — Max Müller — Languages Seen in the Making.*—Comparative philology

has now made an actual investigation into the words and structure of all known languages, and the information sought by the evolutionist lies ready-made to his hand. So far as controversy might be expected to arise here on the theory of development itself, there is none. For the first fact to interest us in this new region is that every student of language seems to have been compelled to give in his adherence to the general theory of evolution. All agree with Renan that "Sans doubte les langues, comme tout ce qui est organisé, sont sujettes à la loi du développement graduel" [without doubt languages, like all that is organized, are subject to the law of gradual development]. And even Max Müller, the least thorough-going from an evolutionary point of view of all philologists, asserts that "no student of the science of language can be anything but an evolutionist, for, wherever he looks, he sees nothing but evolution going on all around him."—DRUMMOND *Ascent of Man*, ch. 5, p. 179. (J. P., 1900.)

1109. EVOLUTION OF PHOSPHORESCENT ORGANS—*Gradation Manifest in Marine Animals.*—It has been known for some years now that the slime secreted by the skin-glands of certain sharks is highly phosphorescent. It is not difficult, then, to understand how it came about that certain fish developed complicated phosphorescent organs.

From the phosphorescent slime secreted by a simple skin-gland to the most complicated eyelike phosphorescent organ, we have a series of intermediate forms that are quite sufficient, even in the imperfect state of our knowledge at the present day, to enable us to understand the outlines of the evolution of these peculiar and interesting organs.—HICKSON *Fauna of the Deep Sea*, ch. 4, p. 77. (A., 1894.)

1110. EVOLUTION OF SCIENCES—*Mind in Relation to Environment.*—At a certain stage in the development of every science a degree of vagueness is what best consists with fertility. On the whole, few recent formulas have done more real service of a rough sort in psychology than the Spencerian one that the essence of mental life and of bodily life are one, namely, "the adjustment of inner to outer relations." Such a formula is vagueness incarnate; but because it takes into account the fact that minds inhabit environments which act on them and on which they in turn react; because, in short, it takes mind in the midst of all its concrete relations, it is immensely more fertile than the old-fashioned "rational psychology," which treated the soul as a detached existent, sufficient unto itself, and assumed to consider only its nature and properties.—JAMES *Psychology*, vol. i, ch. 1, p. 6. (H. H. & Co., 1899.)

1111. EVOLUTION OUT OF FOCUS—*Must Sweep in Whole Truth.*—Evolution was given to the modern world out of focus, was first seen by it out of focus, and has remained out of focus to the present hour. Its general basis has never been reexamined since the time of Mr. Darwin; and not only such speculative sciences as teleology, but working sciences like sociology, have been led astray by a fundamental omission. An evolution theory drawn to scale, and with the lights and shadows properly adjusted—adjusted to the whole truth and reality of Nature and of man—is needed at present as a standard for modern thought.—DRUMMOND *Ascent of Man*, int., p. 6. (J. P., 1900.)

1112. EXACTNESS, NERVELESS, OF THE PHOTOGRAPH—*Nervous Tension May Disqualify the Human Observer.*—To the equatorial telescopes photographic cameras are attached instead of the eyepieces, in the hope that the corona may be made to impress itself on the plate instead of on the eye. The eye is an admirable instrument itself, no doubt; but behind it is a brain, perhaps overwrought with excitement, and responding too completely to the nervous tension which most of us experience when those critical moments are passing so rapidly. The camera can see far less of the corona than the man, but it has no nerves, and what it sets down we may rely on.—LANGLEY *New Astronomy*, ch. 2, p. 47. (H. M. & Co., 1896.)

1113. EXACTNESS OF SCIENCE—*Astronomy Depends upon Hairbreadths and Fractions of a Second.*—Such are the refinements upon which modern astronomy depends for its progress. It is a science of hairbreadths and fractions of a second. It exists only by the rigid enforcement of arduous accuracy and unwearying diligence. Whatever secrets the universe still has in store for man will only be communicated on these terms. They are, it must be acknowledged, difficult to comply with. They involve an unceasing struggle against the infirmities of his nature and the instabilities of his position. But the end is not unworthy the sacrifices demanded. One additional ray of light thrown on the marvels of creation—a single, minutest encroachment upon the strongholds of ignorance—is recompense enough for a lifetime of toil. Or rather, the toil is its own reward, if pursued in the lofty spirit which alone becomes it. For it leads through the abysses of space and the unending vistas of time to the very threshold of that infinity and eternity of which the disclosure is reserved for a life to come.—CLERKE *History of Astronomy*, pt. i, ch. 6, p. 153. (Bl., 1893.)

1114. ——— ——— *Difficulty of Securing a Sample of Water—Infinitesimal Pollution Will Spoil All Results.*—The collection of samples [of water], tho it appears simple enough, is sometimes a difficult and responsible undertaking. Complicated ap-

paratus is rarely necessary, and fallacies will generally be avoided by observing two directions. In the first place, the sample should be chosen as representative as possible of the real substance or conditions we wish to examine. Some authorities advise that it is necessary to allow the tap to run for some minutes previous to collecting the sample; but if we desire to examine for lead chemically or for micro-organisms in the pipes biologically, then such a proceeding would be injudicious. Hence we must use common sense in the selection and obtaining of a sample, following this one guide, namely, to collect as nearly as possible a sample of the exact water the quality of which it is desired to learn. In the second place, we must observe strict bacteriological cleanliness in all our manipulations. This means that we must use only sterilized vessels or flasks for collecting the sample, and in the manipulation required we must be extremely careful to avoid any pollution of air or any addition to the organisms of the water from unsterilized apparatus. A flask polluted in only the most infinitesimal degree will entirely vitiate all results.—NEWMAN *Bacteria*, ch. 2, p. 37. (G. P. P., 1899.)

1115. ——— ——— *Disregarded by Popular Writers.*—Hitherto the endeavor of assigning these levels [of animal intelligence] has been almost exclusively in the hands of popular writers; and as these have, for the most part, merely strung together, with discrimination more or less inadequate, innumerable anecdotes of the display of animal intelligence, their books are valueless as works of reference. So much, indeed, is this the case that comparative psychology has been virtually excluded from the hierarchy of the sciences. If we except the methodical researches of a few distinguished naturalists, it would appear that the phenomena of mind in animals, having constituted so much and so long the theme of unscientific authors, are now considered well-nigh unworthy of serious treatment by scientific methods.—ROMANES *Animal Intelligence*, pref., p. 6. (A., 1899.)

1116. ——— ——— *Early Disinfecting Processes Conspicuously Inexact—Working without a Standard.*—The effects of chemical substances as solutions, or in spray form, upon bacteria have been observed from the earliest days of bacteriology. To some decomposing matter or solution a disinfectant was added and subcultures made. If bacteria continued to develop, the disinfection had not been efficient; if, on the other hand, the subculture remained sterile, disinfection had been complete. From such rough-and-ready methods large deductions were drawn, and it is hardly too much to say that no branch of bacteriology contains such a vast mass of unassimilated and unassimilable statements as that relating to research into disinfectants. Most of the tabulated and recorded results are conspicuous in having no standard as regards bacterial growth. Yet without such a standard results are not comparable.—NEWMAN *Bacteria*, ch. 9, p. 329. (G. P. P., 1899.)

1117. ——— ——— *Influence of Height upon Combustion—Ghostly Flame on Summit of Mont Blanc.*—To determine the influence of height upon the rate of combustion was one of the problems which I set before myself in my journey to the Alps in 1859. On that occasion I invited Dr. Frankland to accompany me, and to undertake the experiments on combustion, while I devoted myself to observations on solar radiation. The plan pursued was this: six candles were purchased at Chamouni and carefully weighed; they were then allowed to burn for an hour in the Hôtel de l'Union, and the loss of weight was determined. The same candles were taken to the summit of Mont Blanc, and, on the morning of August 21, 1859, were allowed to burn for an hour in a tent, which shaded them from the sun and sheltered them from the wind. The aspect of the six flames at the summit surprised us both. They seemed the mere ghosts of the flames produced at Chamouni—enlarged, pale, feeble, and suggesting a greatly diminished energy of combustion. The candles being carefully weighed on our return, the unexpected fact was revealed that the quantity of stearin consumed above was almost precisely the same as that consumed below. Thus, tho the light-giving power of the flame was diminished in an extraordinary degree, the rapidity of the combustion was unchanged. This curious result is to be ascribed mainly to the mobility of the air at this great height. The particles of oxygen could penetrate the flame with comparative freedom, thus destroying its light, and making atonement for the smallness of their number by the rapidity of their action. I find, indeed, that by reducing the density of ordinary atmospheric air to one-half, we nearly double the mobility of its atoms.—TYNDALL *Heat a Mode of Motion*, lect. 3, p. 64. (A., 1900.)

1118. ——— ——— *Light as an Indicator of Motion—The Faintest Thrills of Heat or Magnetism Measured.*—Now, this law of angular reflection [the law, viz.: that *when a mirror rotates, the angular velocity of a beam reflected from it is twice that of the reflecting mirror*], coupled with the fact that a beam of light possesses no weight, gives us the means of magnifying small motions to an extraordinary degree. Thus, by attaching mirrors to his suspended magnets, and by watching the images of divided scales reflected from the mirrors, the celebrated Gauss was able to detect the slightest thrill of variation on the part of the earth's magnetic force. By a similar arrangement the feeble attractions and repulsions of the diamagnetic force have been made manifest. The minute elongation of a bar of metal by the mere warmth of the

hand may be so magnified by this method as to cause the index-beam to move through 20 or 30 feet. The lengthening of a bar of iron when it is magnetized may be also thus demonstrated.—TYNDALL *Lectures on Light,* lect. 1, p. 12. (A., 1898.)

1119. ——— ——— *Lines of the Spectrum Made to Tell Their Story—Minerals in the Sun—Helium Found on Earth.*—It was already known that the various chemical elements, when heated to incandescence, produce spectra consisting of a group of colored bands, and it had been noticed that some of these bands, as the yellow band of sodium, corresponded in position with certain black lines in the solar spectrum. Kirchoff's discovery consisted in showing that, when the light from an incandescent body passes through the same substance in a state of vapor, much of it is absorbed, and the colored bands become replaced by black lines. The black lines in the solar spectrum are due, on this theory, to the light from the incandescent body of the sun being partially absorbed in passing through the vapors which surround it. This theory led to a careful examination of the spectra of all the known elements, and on comparing them with the solar spectrum it was found that in many cases the colored bands of the elements corresponded exactly in position with certain groups of black lines in the solar spectrum. Thus hydrogen, sodium, iron, magnesium, copper, zinc, calcium, and many other elements have been proved to exist in the sun. Some outstanding solar lines, which did not correspond to any known terrestrial element, were supposed to indicate an element peculiar to the sun, which was therefore named helium. Quite recently this element has been discovered in a rare mineral, and its colored spectrum is found to correspond exactly to the dark lines in the solar spectrum on which it was founded, thus adding a final proof of the correctness of the theory, and affording a striking example of its value as an instrument of research.—WALLACE *The Wonderful Century,* ch. 6, p. 43. (D. M. & Co., 1899.)

1120. ——— ——— *Measurement of Vision—Light-intensities Measurable by Galvanic Current.*—It only remains for us in this case to determine the least light-intensity, which is in absolute darkness just noticeably brighter than the black of the field of vision. We can most easily obtain very weak light-intensities of this kind by passing a constant current through a metal wire. As we increase the intensity of the current, the wire becomes hotter and hotter, till at a definite temperature it begins to be luminous. And since we can graduate the strength of a galvanic current at our pleasure, the intensity at which the luminosity of the wire becomes just noticeable can be readily determined. We have then only to compare its objective value with that of other known light-intensities. It has been found in this way that the just noticeable intensity of light is approximately $\frac{1}{300}$ of the light of the full moon reflected from white paper.—WUNDT *Psychology,* lect. 4, p. 54. (Son. & Co., 1896.)

1121. ——— ——— *Measuring the Salmon's Leap.*—The distances up rivers to which salmon will swim in the spawning season is no less surprising than the energy with which they perform the feat, and the determination with which they overcome all obstacles. They reach Bohemia by the Elbe and Switzerland by the Rhine. On encountering a waterfall they display astonishing agility and perseverance in surmounting the obstacle. This fact, of course, is well known to all salmon-fishers; but the actual vertical height to which a well-grown salmon is able to leap has only recently (1886) been made the subject of exact measurement. By means of upright posts fixed upon the banks of a stream on either side of a waterfall in Norway, Professor Landmark has determined that this fish is able to rise through the air, by a single spring, a vertical distance of sixteen feet. The salmon, therefore, may be said to have no competitor in its performance of the high jump, unless it be the kangaroo, as to whose powers in this respect I have not been able to find trustworthy information.—ROMANES *Animal Intelligence,* ch. 8, p. 249. (A., 1899.)

1122. ——— ——— *Minute Displacement of Sirius—Still More Minute Correction.*—The annual displacement of Sirius may be thus illustrated: On a clear moonlight night let the reader notice the apparent diameter of the moon. Next let him try to conceive that diameter divided into about 3,800 equal parts. Then the greatest displacement of Sirius is equal to one of those minute portions. Sirius in fact appears to circle round a minute oval path on the heavens, having for its longest diameter a space equal to about the 3,800th part of the moon's apparent diameter. Now, the error of the earlier estimate (supposing that estimate erroneous) consisted in setting the displacement of Sirius at about the 6,300th part of the moon's diameter—the difference between the two estimates corresponding to about the 9,500th part of the moon's apparent diameter. If the reader will but conceive the moon's apparent diameter divided into about 100 parts, and one of these parts again into 100 parts, he will be able to form an idea of the exceeding minuteness of the quantity by which astronomers suppose that their first estimate was erroneous.—PROCTOR *Our Place among Infinities,* p. 166. (L. G. & Co., 1897.)

1123. ——— ——— *Newton Calculates the Depth of Fine Film of Air.*—Newton compared the tints obtained in this way [a plate of glass with a plane surface being laid on a plano-convex glass lens of very f. ble curvature] with the tints of his soap-

bubble, and he calculated the corresponding thickness. How he did this may be thus made plain to you: Suppose the water of the ocean to be absolutely smooth; it would then accurately represent the earth's curved surface. Let a perfectly horizontal plane touch the surface at any point. Knowing the earth's diameter, any engineer or mathematician in this room could tell you how far the sea's surface will lie below this plane, at the distance of a yard, ten yards, a hundred yards, or a thousand yards from the point of contact of the plane and the sea. It is common, indeed, in leveling operations, to allow for the curvature of the earth. Newton's calculation was precisely similar. His plane glass was a tangent to his curved one. From its refractive index and focal distance he determined the diameter of the sphere of which his curved glass formed a segment, he measured the distances of his rings from the place of contact, and he calculated the depth between the tangent plane and the curved surface exactly as the engineer would calculate the distance between his tangent plane and the surface of the sea. The wonder is that, where such infinitesimal distances are involved, Newton, with the means at his disposal, could have worked with such marvelous exactitude.—TYNDALL *Lectures on Light*, lect. 2, p. 74. (A., 1898.)

1124. ——— ——— *Pasteur's Care in Experiments—No Life in Glacier Air.*—The caution exercised by Pasteur, both in the execution of his experiments and in the reasoning based upon them, is perfectly evident to those who, through the practise of severe experimental inquiry, have rendered themselves competent to judge of good experimental work. He found germs in the mercury used to isolate his air. He was never sure that they did not cling to the instruments he employed, or to his own person. Thus when he opened his hermetically sealed flasks upon the Mer de Glace, he had his eye upon the file used to detach the drawn-out necks of his bottles, and he was careful to stand to leeward when each flask was opened. Using these precautions, he found the glacier air incompetent, in nineteen cases out of twenty, to generate life; while similar flasks, opened amid the vegetation of the lowlands, were soon crowded with living things.—TYNDALL *Floating Matter of the Air*, p. 33. (A., 1895.)

1125. ——— ——— *Precise Quantitative Measurements Needed—Refraction of Light—Kepler a Theorist on the Observations of Others—The "Personal Equation" in Science.*—As regards the refraction of light, the course of real inquiry was resumed in 1100 by an Arabian philosopher named Alhazen. Then it was taken up in succession by Roger Bacon, Vitellio, and Kepler. One of the most important occupations of science is the determination, by precise measurements, of the quantitative relations of phenomena; the value of such measurements depending greatly upon the skill and conscientiousness of the man who makes them. Vitellio appears to have been both skilful and conscientious, while Kepler's habit was to rummage through the observations of his predecessors, to look at them in all lights, and thus distil from them the principles which united them. He had done this with the astronomical measurements of Tycho Brahe, and had extracted from them the celebrated "laws of Kepler." He did it also with Vitellio's measurements of refraction. But in this case he was not successful. The principle, tho a simple one, escaped him, and it was first discovered by Willebrod Snell, about the year 1621.—TYNDALL *Lectures on Light*, lect. 1, p. 14. (A., 1898.)

1126. ——— ——— *Specimens Once Vaguely Located—Loose Methods Now Discarded.*—Fifty years ago the exact locality from which any animal came seemed an unimportant fact in its scientific history, for the bearing of this question on that of origin was not then perceived. To say that any specimen came from South America was quite enough; to specify that it came from Brazil, from the Amazons, the San Francisco, or the La Plata, seemed a marvelous accuracy in the observers. In the museum at Paris, for instance, there are many specimens entered as coming from New York or from Pará; but all that is absolutely known about them is that they were shipped from those seaports. Nobody knows exactly where they were collected. So there are specimens entered as coming from the Rio San Francisco, but it is by no means sure that they came exclusively from that water-basin. All this kind of investigation is far too loose for our present [1865] object.—AGASSIZ *Journey in Brazil*, ch. 1, p. 9. (H. M. & Co., 1896.)

1127. ——— ——— *Velocity of Light Determined.*—The velocity of light, as is well known, was first determined by irregularities in the time of the eclipses of Jupiter's satellites, which were found to occur earlier or later than the calculated times, according as we were near to or far from the planet. It was thus found that it required [about] eight minutes for light to travel from the sun to the earth, a distance of a little more than ninety millions of miles: so that light travels about 186,000 miles in a single second of time. It would seem at first sight impossible to measure the time taken by light in traveling a mile, yet means have been discovered to do this, and even to measure the time taken for light to traverse a few feet from one side of a room to the other. Yet more, this method of measuring the velocity of light has, by successive refinements, become so accurate that it is now considered to be the most satisfactory method of determining the mean distance of the sun from the earth, a distance

which serves as the unit of measurement for the solar system and the whole stellar universe.—WALLACE *The Wonderful Century*, ch. 8, p. 60. (D. M. & Co., 1899.)

1128. EXCESS OF CONCENTRATION —*Pure Waters Evaporated to Bitterness.*—The streams flowing to the [Great Salt] lake rise in the high mountains to the east and are clear and limpid, and of such purity that only chemical tests reveal the presence of the mineral matter they have dissolved from the rocks and soils. Several of these streams are truly rivers in volume, as well as in name, and send a never-ceasing flood to the lake. Their combined volumes average throughout the year about 10,000 cubic feet per second. . . . None of the springs supplying the lake, with a single known exception, of small volumes, are markedly saline. The salts they contain are acquired largely during the upward passage of the water through the sediment of former lakes; and their influence on the chemistry of the present lake is more important than in the case of any other lake in the same region. It is safe to conclude, however, that the combined volumes of the streams and springs now tributary to the lake, if not concentrated by evaporation, would form a water body in which no trace of saline matter would be apparent to the taste.—RUSSELL *Lakes of North America*, ch. 4, p. 80. (G. & Co., 1895.)

1129. EXCESS OF INCREASE TENDS TO EXTERMINATION—The tendency to multiply rapidly, so advantageous in normal seasons, becomes almost fatal to a species in seasons of exceptional abundance. Cover and food without limit enabled the mice to increase at such an amazing rate that the lesser checks interposed by predatory species were for a while inappreciable. But as the mice increased, so did their enemies. Insectivorous and other species acquired the habits of owls and weasels, preying exclusively on them; while to this innumerable army of residents was shortly added multitudes of wandering birds coming from distant regions. No sooner had the herbage perished, depriving the little victims of cover and food, than the effects of the war became apparent. In autumn the earth so teemed with them that one could scarcely walk anywhere without treading on mice; while out of every hollow weed-stalk lying on the ground dozens could be shaken; but so rapidly had they been devoured by the trained army of persecutors that in spring it was hard to find a survivor, even in the barns and houses.—HUDSON *Naturalist in La Plata*, ch. 3, p. 67. (C. & H., 1895.)

1130. EXCITEMENT AN AID TO FAITH—*Emotional Thrill Gives Sense of Reality—Terror on Precipice's Edge.*—Speaking generally, the more a conceived object excites us, the more reality it has. The same object excites us differently at different times. Moral and religious truths come "home" to us far more on some occasions than on others. As Emerson says, "There is a difference between one and another hour of life in their authority and subsequent effect. Our faith comes in moments, . . . yet there is a depth in those brief moments which constrains us to ascribe more reality to them than to all other experiences." The "depth" is partly, no doubt, the insight into wider systems of unified relation, but far more often than that it is the emotional thrill. Thus, to descend to more trivial examples, a man who has no belief in ghosts by daylight will temporarily believe in them when, alone at midnight, he feels his blood curdle at a mysterious sound or vision, his heart thumping, and his legs impelled to flee. The thought of falling when we walk along a curbstone awakens no emotion of dread; so no sense of reality attaches to it, and we are sure we shall not fall. On a precipice's edge, however, the sickening emotion which the notion of a possible fall engenders makes us believe in the latter's imminent reality, and quite unfits us to proceed.—JAMES *Psychology*, vol. ii, ch. 21, p. 307. (H. H. & Co., 1899.)

1131. EXEMPTION FROM ATTACK INSURES INCREASE—*The Passenger-pigeon —The Fulmar Petrel.*—It is usually the amount of destruction which an animal or plant is exposed to, not its rapid multiplication, that determines its numbers in any country. The passenger-pigeon (*Ectopistes migratorius*) is, or rather was, excessively abundant in a certain area in North America, and its enormous migrating flocks darkening the sky for hours have often been described; yet this bird lays only two eggs. The fulmar petrel exists in myriads at St. Kilda and other haunts of the species, yet it lays only one egg. . . . Some of the grasses and sedges, the wild hyacinth, and many buttercups occur in immense profusion over extensive areas, altho each plant produces comparatively few seeds.—WALLACE *Darwinism*, ch. 2, p. 20. (Hum., 1889.)

1132. EXPANSION EXPLAINED AS VIBRATION—*Planet Viewed through Heated Air.*—But how are we to picture such dilatation [expansion by heat] in accordance with the theory which regards heat as a mode of motion? The comparison of a very great thing with an indefinitely small one will here help us to a clear conception. I once approached Gibraltar on a fine starlight night when the planet Jupiter was sharply defined on a clear sky. On walking, however, past the funnel of the steamer, so as to bring the heated air between me and it, the planet suddenly augmented in apparent size, losing at the same time part of its sharpness of definition. The expansion was evidently due to the heated air, causing the image of the planet to quiver on the retina. This quivering was in all directions, and it was so rapid that the various motions blended upon the retina to a disk of aug-

mented size. If, instead of the planet's light being acted upon by heated air, the planet itself had danced in all directions to and fro, the same apparent augmentation of the disk would have ensued. Jupiter, thus quivering, would virtually fill a greater space than if he were still. The case is similar with our dancing atoms. When, instead of a motionless atom, we have a vibrating one, we must make room not only for the atom itself, but also for the distance over which its motion stretches. The case may be further illustrated by a tuning-fork. Motionless as it is at present, its prongs fit into a certain space; thrown into vibration, the prongs strike against their boundaries, demanding more room.—TYNDALL *Heat a Mode of Motion*, lect. 4, p. 92. (A., 1900.)

1133. EXPANSION OF WATER IN FREEZING—*One Instance under General Law.*—At this temperature [a shade over 39° F.] water attains its maximum density. Seven degrees below this temperature, or at 32° F., the liquid begins to turn into solid crystals of ice, which swims upon water because it is bulkier for a given weight. In fact, this halt of the approaching molecules at the temperature of 39° is but the preparation for the subsequent act of crystallization in which the expansion by cold culminates. Up to the point of solidification the increase of volume is slow and gradual; while in the act of solidification it is sudden and of overwhelming strength. By this force of expansion the Florentine academicians long ago burst a sphere of copper nearly three-quarters of an inch in thickness. . . .

Water is not a solitary exception to an otherwise general law. There are other molecules than those of this liquid which require more room in the solid crystalline condition than in the adjacent molten condition. Iron is a case in point. Solid iron floats upon molten iron exactly as ice floats upon water. Bismuth is a still more impressive case, and we could shiver a bomb as certainly by the solidification of bismuth as by that of water.—TYNDALL *Forms of Water*, pp. 121-124. (A., 1899.)

1134. EXPANSION, UNEQUAL, OF GLASS—*Apparent Strength a Source of Weakness.*—In applying heat to glass vessels, thickness is a source of weakness or liability to fracture, on account of the unequal expansion of the two sides, due to inequality of temperature, which, of course, increases with the thickness of the glass. Besides this, the thickness increases the leverage of the breaking strain.—WILLIAMS *Chemistry of Cookery*, ch. 2, p. 8. (A., 1900.)

1135. EXPECTATION OF SCIENCE VERIFIED—*Meteorites the Dust of Decaying Comets.*—The missing comet [Biela's] was next due at perihelion in the year 1872, and the probability was contemplated by both Weiss and Galle of its being replaced by a copious discharge of falling stars. The precise date of the occurrence was not easily determinable, but Galle thought the chances in favor of November 28. The event anticipated the prediction by twenty-four hours. Scarcely had the sun set in Western Europe on November 27 when it became evident that Biela's comet was shedding over us the pulverized products of its disintegration. The meteors came in volleys from the foot of the Chained Lady, their numbers at times baffling the attempt to keep a reckoning. At Moncalieri, about 8 p. m., they constituted (as Father Denza said) a "real rain of fire." Four observers counted, on an average, four hundred each minute and a half; and not a few fire-balls, equaling the moon in diameter, traversed the sky.—CLERKE *History of Astronomy*, pt. ii, ch. 10, p. 406. (Bl., 1893.)

1136. EXPECTATIONS, EXTRAVAGANT, OF NEW INVENTION—*Proposed Two-mile Telescope.*—The advantages which were at that period [17th century] supposed to be obtainable only by gigantic length led great minds, as is frequently the case, to extravagant expectations. Auzout considered it necessary to refute Hooke, who is said to have proposed the use of telescopes having a length of upward of 10,000 feet (or nearly two miles), in order to see animals in the moon.—HUMBOLDT *Cosmos*, vol. iii, p. 63. (H., 1897.)

1137. EXPECTATIONS OF NATURALISTS DISAPPOINTED—*Ocean Depths Reveal No Wholly New Life.*—It seemed probable, before the despatch of the "Challenger" expedition, that when the dredge and the trawl should be successfully employed in depths of over 2,000 fathoms, a new and remarkable fauna would be brought to light. Some naturalists thought it even possible that, not only would many genera be found alive that are known to us only by their fossilized skeletons in the Secondary and Tertiary rocks, but that there might be many other new creatures whose anatomy would throw much light on the theories of the evolution of the animal series. But none of the great expeditions that have sailed since the year 1874 have yet succeeded in showing that the hopes and wishes of these naturalists were really justified. Altho thousands of species of animals have been described in the volumes that have been devoted to deep-sea work, the number of the sub-kingdoms and classes remains the same, and indeed the number of new families and genera has not been increased in any very unprecedented manner.—HICKSON *Fauna of the Deep Sea*, ch. 5, p. 86. (A., 1894.)

1138. EXPENDITURE, PROFUSE, IN NATURE—*Advantages of Cross-fertilization—Species That Have Perished.*—Profuse expenditure is nothing unusual under Nature, as we see with the pollen of wind-fertilized plants, and in the multitude of seeds and seedlings produced by most plants in com-

parison with the few that reach maturity. In other cases the paucity of the flowers that are impregnated may be due to the proper insects having become rare under the incessant changes to which the world is subject: or to other plants, which are more highly attractive to the proper insects, having increased in number. We know that certain orchids require certain insects for their fertilization. . . . . In those cases in which only a few flowers are impregnated owing to the proper insects visiting only a few, this may be a great injury to the plant; and many hundred species throughout the world have been thus exterminated, those which survive having been favored in some other way. On the other hand, the few seeds which are produced in these cases will be the product of cross-fertilization, and this, as we now positively know, is an immense advantage to most plants.—DARWIN *Fertilization of Orchids*, ch. 9, p. 281. (A., 1898.)

1139. EXPERIENCE, BEES LEARNING BY—*Defense against Death's-head Moth.*—Huber first noticed the remarkable fact that when beehives are attacked by the death's-head moth the bees close the entrance of their hive with wax and propolis to keep out the marauder. The barricade, which is built immediately behind the gateway, completely stops it up—only a small hole being left large enough to admit a bee, and therefore of course too small to admit the moth. Huber specially states that it was not until the beehives had been repeatedly attacked and robbed by the death's-head moth, that the bees closed the entrance of their hive with wax and propolis. Pure instinct would have induced the bees to provide against the first attack. Huber also observed that a wall built in 1804 against the death's-head hawk-moth was destroyed in 1805. In the latter year there were no death's-head moths, nor were any seen during the following. But in the autumn of 1807 a large number again appeared, and the bees at once protected themselves against their enemies.—ROMANES *Animal Intelligence*, ch. 4, p. 184. (A., 1899.)

1140. EXPERIENCE INCLUDES THE LAWS OF MIND—*Instantaneous Perception May Teach Eternal Truth.*—But if "experience" is to be upheld as in any sense the ground and basis of all our knowledge, it must be understood as embracing that most important of all kinds of experience in the study of Nature—the experience we have of the laws of mind. It is one of the most certain of those laws, that in proportion as the powers of the understanding are well developed, and are prepared by previous training for the interpretation of natural facts, there is no relation whatever between the time occupied in the observation of phenomena and the breadth or sweep of the conclusions which may be arrived at from them. A single glance, lasting not above a moment, may awaken the recognition of truths as wide as the universe and as everlasting as time itself.—ARGYLL *Unity of Nature*, ch. 4, p. 86. (Burt.)

1141. EXPERIENCE, LEARNING BY, A PROOF OF MIND—This proof [of the existence of mind] is in all cases and in its last analysis the fact of a living organism showing itself able to learn by its own individual experience. Wherever we find an animal able to do this we have the same right to predicate mind as existing in such an animal that we have to predicate it as existing in any human being other than ourselves.—ROMANES *Animal Intelligence*, int., p. 7. (A., 1899.)

1142. EXPERIENCE THE FOUNDATION OF REMEMBRANCE—Phenomena have absolutely no power to influence our ideas until they have first impressed our senses and our brain. The bare existence of a past fact is no ground for our remembering it. Unless we have seen it, or somehow undergone it, we shall never know of its having been.—JAMES *Psychology*, vol. i, ch. 1, p. 4. (H. H. & Co., 1899.)

1143. EXPERIENCE THE STARTING-POINT OF SCIENCE—We are far distant from the period when it was thought possible to concentrate all sensuous perceptions into the unity of one sole idea of Nature. The true path was indicated upward of a century before Lord Bacon's time, by Leonardo da Vinci, in these few words: "Cominciare dall' esperienza e per mezzo di questa scoprirne la ragione" (commence by experience, and by means of this discover the reason). In many groups of phenomena we must still content ourselves with the recognition of empirical laws; but the highest and more rarely attained aim of all natural inquiry must ever be the discovery of their causal connection. The most satisfactory and distinct evidence will always appear where the laws of phenomena admit of being referred to mathematical principles of explanation.—HUMBOLDT *Cosmos*, vol. iii, p. 10. (H., 1897.)

1144. EXPERIMENT CHANGES PRECONCEIVED THEORY — *Glacier-motion.*—Agassiz appears to have been the first to commence, in 1841, a series of exact measurements to ascertain the laws of glacier-motion, and he soon discovered, contrary to his preconceived notions, that the stream of ice moved more slowly at the sides than at the center, and faster in the middle region of the glacier than at its extremity. Professor James Forbes, who had joined Mr. Agassiz during his earlier investigations in the Alps, undertook himself an independent series of experiments, which he followed up with great perseverance, to determine the laws of glacier-motion. These he found to agree very closely with the laws governing the course of rivers, their progress being greater in the center than at the sides, and more rapid at the surface than at the bot-

tom. This fact was verified by carefully fixing a great number of marks in the ice, arranged in a straight line, which gradually assumed a beautiful curve, the middle part pointing down the glacier, and showing a velocity there double or treble that of the lateral parts. He ascertained that the rate of advance by night was nearly the same as by day, and that even the hourly march of the icy stream could be detected, altho the progress might not amount to more than six or seven inches in twelve hours. By the incessant tho invisible advance of the marks placed on the ice, "time," says Mr. Forbes, "was marked out as by a shadow on a dial, and the unequivocal evidence which I obtained, that even while walking on a glacier we are, day by day, and hour by hour, imperceptibly carried on by the resistless flow of the icy stream, filled me with admiration."—LYELL *Geology*, ch. 15, p. 224. (A., 1854.)

1145. EXPERIMENT CONFIRMS THEORY—*Galileo with Telescope Verifies Reasonings of Copernicus—Jupiter with His Satellites a Little Universe.*—In 1609 Galileo constructed his telescope, and very soon discovered the satellites of Jupiter. This at once confirmed the Copernican theory, by opening before the eyes of men another system, subordinate to the solar, of heavenly bodies revolving about their primaries, thus giving an analogon of the greater. The subsequent discovery by the same instrument of the phases of Venus at once confirmed the new theory of the revolution of the planets about the sun, and answered an objection against it by explaining why Venus did not appear larger when nearer the beholder. Copernicus furnished the suggestion by reflecting on the known fact that the apparent places of objects may be accounted for by the motion of one or both, and that the solution or theory which was the simplest was to be preferred. Galileo, by his telescope, prepared the way for the experiment by enabling observers, in a certain sense, to observe for themselves which moved—the sun or the earth.—PORTER *Human Intellect*, pt. iii, ch. 8, p. 477. (S., 1899.)

1146. ——— ——— *Insectivorous Plants "Fed" and "Starved"—Rapid Growth Due to Animal Food.*—Since the publication of the first edition, several experiments have been made to determine whether insectivorous plants are able to profit by an animal diet.

My experiments were published in *Linnean Society's Journal*, and almost simultaneously the results of Kellermann and Von Raumer were given in the *Botanische Zeitung*. My experiments were begun in June, 1877, when the plants were collected and planted in six ordinary soup-plates. Each plate was divided by a low partition into two sets, and the least flourishing half of each culture was selected to be "fed," while the rest of the plants were destined to be "starved." The plants were prevented from catching insects for themselves by means of a covering of fine gauze, so that the only animal food which they obtained was supplied in very minute pieces of roast meat given to the "fed" plants, but withheld from the "starved" ones. After only ten days the difference between the "fed" and "starved" plants was clearly visible: the fed plants were of brighter green, and the tentacles of a more lively red. At the end of August the plants were compared by number, weight, and measurement, with the following striking results:

	Starved.	Fed.
Weight (without flower-stems)	100	121.5
Number of flower-stems	100	164.9
Weight of stems	100	231.9
Number of capsules	100	194.4
Total calculated weight of seed	100	379.7
Total calculated number of seeds	100	241.5

—DARWIN *Insectivorous Plants* (addition by FRANCIS DARWIN), ch. 1, p. 15. (A., 1900.)

1147. ——— ——— *Scientific Assurance Fulfilled.*—By way of experiment, the sinking of a well was commenced at Paris in 1834, which had reached, in November, 1839, a depth of more than 1,600 English feet, and yet no water ascended to the surface. The government were persuaded by M. Arago to persevere, if necessary, to the depth of more than 2,000 feet; but when they had descended above 1,800 English feet below the surface, the water rose through the tube (which was about ten inches in diameter), so as to discharge half a million of gallons of limpid water every twenty-four hours. The temperature of the water increased at the rate of 1° 8′ F. for every 101 English feet as they went down, the result agreeing very closely with the anticipations of the scientific advisers of this most spirited undertaking.—LYELL *Principles of Geology*, bk. ii, ch. 16, p. 234. (A., 1854.)

1148. EXPERIMENT NECESSARY FOR THE FULL DEVELOPMENT OF A SCIENCE—*What the Ancients Knew of Light.*—But other objects than the motions of the stars attracted the attention of the ancient world. Light was a familiar phenomenon, and from the earliest times we find men's minds busy with the attempt to render some account of it. But without experiment, which belongs to a later stage of scientific development, little progress could be made in this subject. The ancients, accordingly, were far less successful in dealing with light than in dealing with solar and stellar motions. Still they did make some progress. They satisfied themselves that light moved in straight lines; they knew also that light was reflected from polished surfaces, and that the angle of incidence of the rays of light was equal to the angle of reflection. These two results of ancient scientific curiosity constitute the starting-point of [modern scientific knowledge on the subject].—TYNDALL *Lectures on Light*, lect. 1, p. 5. (A., 1898.)

1149. EXPERIMENT REFUTES ANCIENT THEORY—*Scholastic Dictum Shattered at Leaning Tower of Pisa.*—The notion of the attractive force of the earth, unchecked by any right conception of the action of force in producing motion, led the ancients into a very strange error. As the "weight" of a body is the expression of the downward "pull" which the earth exerts upon it, it seemed natural to suppose that the rate of the fall of any heavy body to the ground would increase in proportion to that weight, so that a body weighing ten pounds would fall ten times as fast as a body weighing one pound. And this was formulated as a "law" by Aristotle, and accepted by "educated" mankind as such for nearly two thousand years. . . . Galileo . . . saw that it must be erroneous, as taking no account of the very obvious consideration that while the "pull" of the earth on the weight of ten pounds is ten times as great as it is upon the weight of one pound, it has to give motion to ten times the mass; so that the rates of fall of the two bodies would be the same. His teaching on this subject being opposed by his colleagues, Galileo, in the presence of the whole university, ascended the Leaning Tower, and, dropping from its summit bodies of different weights, he showed that (with an inconsiderable difference, due to the resistance of the air) they reached the bottom in the same times. As the monument of an experiment which gave the death-blow to the unscientific legislation of Aristotle, and prepared the way for the scientific legislation of Newton, the Leaning Tower of Pisa, beautiful in itself as an architectural work, has a far grander interest for all who can appreciate this great step in the emancipation of thought.—CARPENTER *Nature and Man*, p. 371. (A., 1889.)

1150. EXPERIMENT SUPERIOR TO ORDINARY OBSERVATION—*Electricity and Thunder-storm.*—When the scientific investigator is inquiring into the causes of a phenomenon, he does not confine himself to the investigation of things as they are given in ordinary perception. That would never take him to his goal, tho he had at his command the experiences of all time. Thunder-storms have been recorded, indeed carefully described, since the first beginnings of history; but what a storm was could not be explained until the phenomena of electricity had become familiar, until electrical machines had been constructed and experiments made with them. Then the matter was easy. For when once the effects of a storm had been observed and compared with the effect of an electric spark, the inference was plain that the discharge of the machine was simply a storm in miniature. What the observation of a thousand years had left unexplained was understood in the light of a single experiment.—WUNDT *Psychology*, lect. 1, p. 9. (Son. & Co., 1896.)

1151. EXPERIMENT THOUGHT DEGRADING—An aged and learned professor of therapeutics, who occupied himself much with the reorganization of the universities, was urgent with me to divide physiology, in order to restore the good old time; that I myself should lecture on the really intellectual part, and should hand over the lower experimental part to a colleague whom he regarded as good enough for the purpose. He quite gave me up when I said that I myself considered experiments to be the true basis of science.—HELMHOLTZ *Popular Lectures*, lect. 5, p. 219. (L. G. & Co., 1898.)

1152. EXPERIMENTER DIFFERS FROM OBSERVER—I do not question his [Pouchet's] ability as an observer, but the inquiry needed a disciplined experimenter. This latter implies not mere ability to look at things as Nature offers them to our inspection, but to force her to show herself under conditions prescribed by the experimenter himself.—TYNDALL *Floating Matter of the Air*, p. 284. (A., 1895.)

1153. EXPERIMENTS CUMULATIVE—*Demonstrations of Science — Pasteur Traces Fermentation to Living Organisms.*—As in all the conclusions arrived at by Pasteur, so in those relating to fermentation, there were a number of different experiments which were performed by him to elucidate the same point. We will choose one of many in relation to fermentation. If a sugary solution of carbonate of lime is left to itself, after a time it begins to effervesce, carbonic acid is evolved, and lactic acid is formed; and this latter decomposes the carbonate of lime to form lactate of lime. This lactic acid is formed, so to speak, at the expense of the sugar, which little by little disappears. Pasteur demonstrated the cause of this transformation of sugar into lactic acid to be a thin layer of organic matter consisting of extremely small moving organisms. If these be withheld or destroyed in the fermenting fluid, fermentation will cease. If a trace of this gray material be introduced into sterile milk or sterile solution of sugar, the same process is set up, and lactic acid fermentation occurs.—NEWMAN *Bacteria*, ch. 4, p. 112. (G. P. P., 1899.)

1154. EXPERT, INTUITION OF—*Accumulated Associations from Long Experience.*—Saturated with experience of a particular class of materials, an expert intuitively feels whether a newly reported fact is probable or not, whether a proposed hypothesis is worthless or the reverse. He instinctively knows that, in a novel case, this and not that will be the promising course of action. The well-known story of the old judge advising the new one never to give reasons for his decisions—"the decisions will probably be right, the reasons will surely be wrong"—illustrates this. The doctor will

feel that the patient is doomed, the dentist will have a premonition that the tooth will break, tho neither can articulate a reason for his foreboding. The reason lies embedded, but not yet laid bare, in all the countless previous cases dimly suggested by the actual one, all calling up the same conclusion, which the adept thus finds himself swept on to, he knows not how or why.—JAMES *Psychology*, vol. ii, ch. 22, p. 365. (H. H. & Co., 1899.)

1155. EXPLORATION OF ANCIENT GEOLOGIC LANDS AND SEAS—*A Future in the Study of the Past.*—As the ancient geographers were laying the foundation for all our modern knowledge of the present conformation of the globe, so are the geologists of the nineteenth century preparing the ground for future investigators, whose work will be as far in advance of theirs as are the delineations of Carl Ritter, the great master of physical geography in our age, in advance of the map drawn by the old Alexandrian geographer. We shall have our geological explorers and discoverers in the lands and seas of past times, as we have had in those of the present—our Columbuses, our Captain Cooks, our Livingstones in geology, as we have had in geography. There are undiscovered continents and rivers and inland seas in the past world to exercise the ingenuity, courage, and perseverance of men, after they shall have solved all the problems, sounded all the depths, and scaled all the heights of the present surface of the earth.—AGASSIZ *Geological Sketches*, ser. i, ch. 4, p. 97. (H. M. & Co., 1896.)

1156. EXPLORATION OF DEEP SEA—*Required Governmental Aid—Science Demands Concentration of Human Power.*—But the men of science fifty years ago, pushing their inquiries as to the character of the sea-fauna into deeper and deeper water, at length demanded information as to the existence of forms of animal life in the greatest depths. Unable themselves to bear the heavy expenses involved in such an investigation, they sought for and obtained the assistance of the government, in the form of national ships, for the work, and then our knowledge of the depths of the great ocean may be said to have commenced.—HICKSON *Fauna of the Deep Sea*, pref., p. 8. (A., 1894.)

1157. EXPORTATION OF PRODUCTS AND EXHAUSTION OF SOIL—*Home Market Permits Replacement—Poverty of Merely Agricultural Communities.*—The exportation of agricultural products becomes, therefore, a slow but certain method of securing soil exhaustion, and this accounts for the fact that countries, or those portions of countries, which are devoted to almost exclusive agricultural pursuits, thus causing a continuous exportation of agricultural products, become the homes, not of the richest, but of the poorest communities.

It would be useless to deny, in this connection, that our own country, with a soil enriched by centuries of accumulating nitrogen, has grown rich from its agricultural exports. But when the last of our virgin soil shall have been placed under cultivation, a continuous stream of such exports will certainly impoverish the nation, and reduce all who practise such agriculture to the condition which has already been reached by those who have for years grown tobacco, corn, cotton, and wheat on the same soil, and sold the products without paying back to the field the percentage of profits which was its due.

On the other hand, the farmer who is fortunate enough to be permitted to patronize the home market, who sells his maize and takes home a load of manure, adds not only to the plethora of his purse, but also to the fertility of his soil.

Thus in the light of agricultural chemistry we see clearly the deep scientific basis of the teachings of political economy which show the value of the home market. While, therefore, the statement made at the commencement of this address, that the chief factor in the prosperity of a country is its agriculture, remains in every sense true, yet from the data discussed it as readily appears that agricultural prosperity is most intimately connected with the advancement of every other industry. Agricultural chemistry teaches the farmer to welcome the furnace and the mill, for in their proximity he secures a sure return to his fields of the plant-foods removed in his crops.—WILEY *Economical Aspects of Agricultural Chemistry (Proceedings of the Amer. Assoc. for Advancement of Science*, vol. xxxv).

1158. EXTENSION OF INDIVIDUALITY—*Clothing Is Almost Part of Self.*—The body is the innermost part of the material self in each of us; and certain parts of the body seem more intimately ours than the rest. The clothes come next. The old saying that the human person is composed of three parts—soul, body, and clothes—is more than a joke. We so appropriate our clothes and identify ourselves with them that there are few of us who, if asked to choose between having a beautiful body clad in raiment perpetually shabby and unclean, and having an ugly and blemished form always spotlessly attired, would not hesitate a moment before making a decisive reply.—JAMES *Psychology*, vol. i, ch. 10, p. 292. (H. H. & Co., 1899.)

1159. EXTENSION OF KNOWLEDGE THROUGH CONTACT WITH EXTERNAL WORLD—*Promise for Future.*—If art may be said to dwell within the magic circle of the imagination, the extension of knowledge, on the other hand, especially depends on contact with the external world, and this becomes more manifold and close in proportion with the increase of general intercourse. The creation of new organs (in-

struments of observation) increases the intellectual and not unfrequently the physical powers of man. More rapid than light, the closed electric current conveys thought and will to the remotest distance. Forces, whose silent operation in elementary nature, and in the delicate cells of organic tissues, still escape our senses, will, when recognized, employed, and awakened to higher activity, at some future time enter within the sphere of the endless chain of means which enable man to subject to his control separate domains of Nature, and to approximate to a more animated recognition of the universe as a whole.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 355. (H., 1897.)

1160. EXTENSION OF SUGGESTION—*From Waves of Sound to Waves of Light—The Luminiferous Ether—A Priori Judgment of the Creator's Will.*—It was known long ago that sound is conveyed in waves or pulses through the air; and no sooner was this truth well housed in the mind than it was transformed into a theoretic conception. It was supposed that light, like sound, might also be the product of wave-motion. But what, in this case, could be the material forming the waves? For the waves of sound we have the air of our atmosphere; but the stretch of imagination which filled all space with a luminiferous ether trembling with the waves of light was so bold as to shock cautious minds. In one of my latest conversations with Sir David Brewster, he said to me that his chief objection to the undulatory theory of light was that he could not think the Creator guilty of so clumsy a contrivance as the filling of space with ether in order to produce light. This, I may say, is very dangerous ground, and the quarrel of science with Sir David, on this point, as with many estimable persons on other points, is, that they profess to know too much about the mind of the Creator.—TYNDALL *Lectures on Light*, lect. 2, p. 48. (A., 1898.)

1161. EXTENSION OF THE SPECTRUM—*The Invisible Outnumber the Visible Rays.*—A layman would suppose that the endeavors of physicists to lengthen out the visible spectrum would cease with the very considerable additions due to the direct photography of rays ultraviolet and ultrared. But the lay mind knows little of the persistence and address of the accomplished physicist, and can only marvel at the mode in which he summons fresh resources from points of the compass at first seeming the farthest removed from his task. . . . Prof. S. P. Langley, Secretary of the Smithsonian Institution at Washington, has refined the galvanometer into an appliance which he styles the bolometer. Its delicate wire, much thinner than a human hair, through which an electric current constantly passes, and sensitive to much less than the ten-millionth of a degree centigrade, is moved by minute steps through the invisible areas of the solar spectrum; each indication of temperature, automatically photographed, comes out as a line which varies in depth of tone with the intensity of the thermal ray. When the device has finished its journey the larger part of the whole breadth of solar radiation rises to view—in all fifteen times as extensive as the spectrum which Newton saw.—ILES *Flame, Electricity, and the Camera*, ch. 24, p. 346. (D. & McC., 1900.)

1162. EXTERMINATION BY DIVERSION OF SUPPLIES—*Willows on Bank Destroy Watercress in Stream.*—A curious example of the struggle between plants has been communicated to me by Mr. John Ennis, a resident in New Zealand. The English watercress grows so luxuriantly in that country as to completely choke up the rivers, sometimes leading to disastrous floods, and necessitating great outlay to keep the stream open. But a natural remedy has now been found in planting willows on the banks. The roots of these trees penetrate the bed of the stream in every direction, and the watercress, unable to obtain the requisite amount of nourishment, gradually disappears.—WALLACE *Darwinism*, ch. 2, p. 17. (Hum., 1889.)

1163. EXTERMINATION OF GAME BY MODERN WEAPONS—*Survival of Hunting as an Amusement.*—The modern hunter has a vastly increased power of killing game, from the use of firearms instead of the bow and spear which came down from savage times. The effect of bringing in guns is seen among the native American buffalo-hunters. They were always reckless in destruction when they once came within reach of the herds, but now with the help of the white man and the use of his rifles there is such slaughter that travelers have found the ground and air for miles foul with the carcasses of buffaloes, killed merely for the hides and tongues. In the civilized world, what with killing off game, and what with the encroachment of agriculture on the wild lands, both the supply and the need of game for man's subsistence have much lessened. But the hunter's life has been from the earliest times man's school of endurance and courage, where success and even trial gives pleasure in one of its intensest forms. Thus it has come to be kept up artificially where its practical use has fallen away. In civilized countries it is seen at its best where it keeps closest to barbaric fatigue and danger, like grouse-shooting in Scotland, or boar-hunting in Austria; but at its meanest, where it has come down to shooting grain-fed pheasants as tame as barn-door fowls.—TYLOR *Anthropology*, ch. 9, p. 210. (A., 1899.)

1164. EXTERMINATION OF PLANT BY PLANT *(Matt. xiii, 7)*—If turf which has long been mown—and the case would be the same with turf closely browsed by quadrupeds—be let to grow, the more vig-

orous plants gradually kill the less vigorous tho fully grown plants; thus out of twenty species grown on a little plot of mown turf (three feet by four) nine species perished, from the other species being allowed to grow up freely.—DARWIN *Origin of Species*, ch. 1, p. 63. (Burt.)

1165. EXTINCTION OF BISON—*Attempts to Avert.*—The buffalo should be a very interesting animal to all American citizens on account of the great danger which exists of its becoming utterly extinct. Only thirty-one years ago they still numbered several millions, more than five millions at the least, whereas in 1889 there were but some twenty individuals in Texas, a few in Colorado, Wyoming, Montana, and Dakota, and two hundred preserved by the Government in the Yellowstone National Park. We have, however, recently been assured that some private individual citizens in the United States are trying to preserve and propagate the buffalo. Canada, which now exhibits such interesting examples of political and social "survival," has been practically conservative as regards the bison, since it appears that some 500 individuals of a race known as the wood-bison still survive there.—MIVART *Types of Animal Life*, ch. 7, p. 178. (L. B. & Co., 1893.)

1166. EXTINCTION OF OTHER SUNS—*A Like Fate Awaits Our Own.*—In other cases obscure heavenly bodies have discovered themselves by their attraction on adjacent bright stars, and the motions of the latter thereby produced. Thus there are extinct suns. The fact that there are such lends new weight to the reasons which permit us to conclude that our sun also is a body which slowly gives out its store of heat, and thus will some time become extinct.—HELMHOLTZ *Popular Lectures*, lect. 4, p. 190. (L. G. & Co., 1898.)

1167. EXTINCTION OF OUR SUN—*Brevity of Human Existence—Insignificance of Man.*—The term of 17,000,000 years which I have given may perhaps become considerably prolonged by the gradual abatement of radiation, by the new accretion of falling meteors, and by still greater condensation than that which I have assumed in that calculation. But we know of no natural process which could spare our sun the fate which has manifestly fallen upon other suns. This is a thought which we only reluctantly admit; it seems to us an insult to the beneficent Creative Power which we otherwise find at work in organisms and especially in living ones. But we must reconcile ourselves to the thought that, however we may consider ourselves to be the center and final object of creation, we are but as dust on the earth; which again is but a speck of dust in the immensity of space; and the previous duration of our race, even if we follow it far beyond our written history, into the era of the lake-dwellings or of the mammoth, is but an instant compared with the primeval times of our planet when living beings existed upon it whose strange and unearthly remains still gaze at us from their ancient tombs; and far more does the duration of our race sink into insignificance compared with the enormous periods during which worlds have been in process of formation, and will still continue to form when our sun is extinguished, and our earth is either solidified in cold or is united with the ignited central body of our system.—HELMHOLTZ *Popular Lectures*, lect. 4, p. 191. (L. G. & Co., 1898.)

1168. EXTINCTION OF SPECIES—*Fossils Show a Succession of Types.*—First, in regard to the vicissitudes of the living creation, all are agreed that the sedimentary strata found in the earth's crust are divisible into a variety of groups, more or less dissimilar in their organic remains and mineral composition. The conclusion universally drawn from the study and comparison of these fossiliferous groups is this, that at successive periods distinct tribes of animals and plants have inhabited the land and waters, and that the organic types of the newer formations are more analogous to species now existing than those of more ancient rocks. If we then turn to the present state of the animate creation, and inquire whether it has now become fixed and stationary, we discover that, on the contrary, it is in a state of continual flux—that there are many causes in action which tend to the extinction of species, and which are conclusive against the doctrine of their unlimited durability. But natural history has been successfully cultivated for so short a period that a few examples only of local, and perhaps but one or two of absolute, extirpation can as yet be proved, and these only where the interference of man has been conspicuous. It will nevertheless appear evident . . . that man is not the only exterminating agent; and that, independently of his intervention, the annihilation of species is promoted by the multiplication and gradual diffusion of every animal or plant.—LYELL *Principles of Geology*, bk. i, ch. 13, p. 181. (A., 1854.)

1169. EXTRAVAGANCES OF NATURE—*Possibilities of Existence Outrun Imagination.*—"Do not be deterred," said Agassiz, in the course of one of the interviews in which he obligingly indulged the writer of these chapters, who had mentioned to him that one of his opinions, just confirmed by the naturalist, had seemed so extraordinary that he had been almost afraid to communicate it—"do not be deterred, if you have examined minutely, by any dread of being deemed extravagant. The possibilities of existence run so deeply into the extravagant that there is scarcely any conception too extraordinary for Nature to realize."—MILLER *The Old Red Sandstone*, ch. 3, p. 52. (G. & L., 1851.)

1170. EXTREMES MEETING—*Ice Preserved under Molten Rock.*—A thick lava-stream must take an enormous period to cool down—probably many hundreds or even thousands of years. It is possible to walk over lava-streams in which at a few inches below the surface the rock is still red-hot, so that a piece of stick is lighted if thrust into a crack. Lava is a very bad conductor of heat, and loose scoriæ and dust are still worse conductors. During the eruption of Vesuvius in 1872, masses of snow which were covered with a thick layer of scoriæ, and afterwards by a stream of lava, were found three years afterwards consolidated into ice, but not melted. The city of Catania is constantly supplied with ice from masses of snow which have been buried under the ejections of Etna.—JUDD *Volcanoes*, ch. 4, p. 110. (A., 1899.)

1171. EXTREMES OF TEMPERATURE IN AMERICA—*In China*—*"Insular Climates" vs. "Excessive Climates."*—In consequence of the more equal temperature of the waters of the ocean, the climate of islands and of coasts differs essentially from that of the interior of continents, the more maritime climate being characterized by mild winters and more temperate summers; for the sea-breezes moderate the cold of winter as well as the heat of summer. When, therefore, we trace round the globe those belts in which the mean annual temperature is the same, we often find great differences in climate; for there are insular climates in which the seasons are nearly equalized, and excessive climates, as they have been termed, where the temperature of winter and summer is strongly contrasted. The whole of Europe, compared with the eastern parts of America and Asia, has an insular climate. The northern part of China, and the Atlantic region of the United States, exhibit "excessive climates." We find at New York, says Humboldt, the summer of Rome and the winter of Copenhagen; at Quebec, the summer of Paris and the winter of Petersburg. At Peking, in China, where the mean temperature of the year is that of the coasts of Brittany, the scorching heats of summer are greater than at Cairo, and the winters as rigorous as at Upsala.—LYELL *Principles of Geology*, bk. i, ch. 7, p. 94. (A., 1854.)

1172. EXTREMES, OPPOSITE, HAVE SIMILAR EFFECTS—*Drought Produces Torpor Like Cold*—*Crocodile*—*Boa-constrictor.*—Gradually, too, the pools of water, which had been protected from evaporation by the now seared foliage of the fan-palm, disappear. As in the icy North, animals become torpid from cold, so here the crocodile and the boa-constrictor lie wrapped in unbroken sleep, deeply buried in the dried soil. Everywhere the drought announces death, yet everywhere the thirsting wanderer is deluded by the phantom of a moving, undulating, watery surface, created by the deceptive play of the reflected rays of light (the mirage). A narrow stratum separates the ground from the distant palm-trees, which seem to hover aloft, owing to the contact of currents of air having different degrees of heat and therefore of density. Shrouded in dark clouds of dust, and tortured by hunger and burning thirst, oxen and horses scour the plain, the one bellowing dismally, the other with outstretched necks snuffing the wind, in the endeavor to detect, by the moisture in the air, the vicinity of some pool of water not yet wholly evaporated.—HUMBOLDT *Views of Nature*, p. 14. (Bell, 1896.)

1173. ——— ——— *Thirst in Arctic Snow-fields, as in Sahara.*—Their [the Eskimos'] drink consists of blood or water: during the greater part of the year they have considerable difficulty in obtaining sufficient water to satisfy their thirst, and it is much too precious to be used for washing. It may seem surprising that people who are surrounded by snow and ice should suffer from want of water, but the amount of heat required to melt snow is so great that a man without the means of obtaining fire might die of thirst in these arctic regions as easily as in the sandy deserts of Africa. Any direct "resort to snow," says Kane, "for the purpose of allaying thirst, was followed by bloody lips and tongue; it burnt like caustic." When the Eskimos visited Captain Parry, they were always anxious for water, which they drank in such quantities "that it was impossible to furnish them with half as much as they desired."—AVEBURY *Prehistoric Times*, ch. 14, p. 476. (A., 1900.)

1174. EYE, IMPERFECT ACHROMATISM OF—*Eyes Differ in Perception of Color.*—The low dispersive power of water masks, as Helmholtz has remarked, the imperfect achromatism of the eye. With the naked eye I can see a distant blue disk sharply defined, but not a red one. I can also see the lines which mark the upper and lower boundaries of a horizontally refracted spectrum sharp at the blue end, but ill-defined at the red end. Projecting a luminous disk upon a screen, and covering one semicircle of the aperture with a red and the other with a blue or green glass, the difference between the apparent sizes of the two semicircles is in my case, and in numerous other cases, extraordinary. Many persons, however, see the apparent sizes of the two semicircles reversed. If with a spectacle-glass I correct the dispersion of the red light over the retina, then the blue ceases to give a sharply defined image. Thus examined the departure of the eye from achromatism appears very gross indeed.—TYNDALL *Lectures on Light*, lect. 1, p. 30. (A., 1898.)

1175. EYES OF DEEP-SEA ANIMALS—*Can Sunlight Reach Them?*—Within the last few years a few authors have maintained that it is quite possible that a few

rays of sunlight do penetrate even to the greatest depths of the ocean—a view mainly based on the fact that so many deep-sea animals possess extremely perfect and complicated eyes and very brilliant color. . . . There seem to me to be very slight grounds for this view.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 23. (A., 1894.)

1176. ——— ——— *Difference in Different Zones.*—In the majority of cases [of deep-sea animals] we find that the eyes are either very large or very small. Only in a small minority of cases do we find that the eyes are recorded to be moderate in size. The relation between the large-eyed forms and the small-eyed forms is not the same in all the regions of deep seas. In depths of 300 to 600 fathoms the majority are large-eyed forms. In depths of over 1,000 fathoms, the small-eyed and blind forms are in a majority, altho many large-eyed forms are to be found.—HICKSON *Fauna of the Deep Sea*, ch. 4, p. 68. (A., 1894.)

1177. FABLE FOUNDED ON FACT—*Story of the Avernian Lake—Deadly Exhalations of Volcanoes.*—Many volcanoes, which have sunk into a state of quiescence or extinction like the Solfatara of Naples, exhibit the same tendency to give off great quantities of the powerfully acid gases which act upon the surrounding rocks. . . . At the so-called Grotto del Cane, beside the Lago Agnano, it is the custom to show the presence of this heavy and poisonous gas by thrusting a dog into it, the poor animal being revived before life is quite extinct by pouring cold water over it. At the Büdos Hegy, or "stinking hill," of Transylvania, carbonic acid and sulfureted hydrogen are emitted in considerable quantities, and it is possible to take a bath of the heavy gas, the head being kept carefully above the constant level of the exhalations.

Altho the stories of the ancient Avernian lake, across which no bird could fly without suffocation, and of the Guèvo Upas, or "Poison Valley," of Java, which it has been said no living being can cross, may not improbably be exaggerations of the actual facts, yet there is a basis of truth in them in the existence of old volcanic fissures and craters which evolve the poisonous sulfureted hydrogen and carbonic acid gases.—JUDD *Volcanoes*, ch. 8, p. 214. (A., 1899.)

1178. FABLES ABOUT ORANG—The orang never stands on its hind legs, and all the pictures representing it as so doing are as false as the assertion that it defends itself with sticks and the like.—HUXLEY *Man's Place in Nature*, p. 207. (Hum.)

1179. FACILITY BECOME A SNARE—*Body Holds Perverted Habit—The Motor Memory a Source of Difficulty as well as of Advantage.*—It is by means of the motor memory that we are able to walk, ride, and skate with ease, and if it were not for it we should have the movement cease directly the attention was suspended or temporarily transferred to some other object. Occasionally, the motor memory is found inconvenient, on account of its having become so firmly established in an erroneous direction as to require every effort of the will to overcome it and establish a new action. Every teacher of dancing, riding, or boxing knows how difficult it is to break a pupil of any habit he may have formed. A boxer, for instance, who has for some considerable time raised his right arm every time he strikes with the left, will find the greatest difficulty in striking with the left and keeping the right still. Examples might be given from all classes of coordinated actions, there being often more trouble in unlearning some erroneous movement than would have been required to learn the new one two or three times over.—ELDRIDGE-GREEN *Memory and Its Cultivation*, pt. i, ch. 4, p. 26. (A., 1900.)

1180. FACT NEEDED TO CORRECT THEORY—*Descartes Supposed Transmission of Light Instantaneous—Ingenious Illustration of a Staff.*—Descartes imagined space to be filled with something that transmitted light instantaneously. Firstly, because, in his experience, no measurable interval was known to exist between the appearance of a flash of light, however distant, and its effect upon consciousness; and secondly, because, as far as his experience went, no physical power is conveyed from place to place without a vehicle. But his imagination helped itself farther by illustrations drawn from the world of fact. "When," he says, "one walks in darkness with staff in hand, the moment the distant end of the staff strikes an obstacle the hand feels it. This explains what might otherwise be thought strange, that the light reaches us instantaneously from the sun. I wish thee to believe that light in the bodies that we call luminous is nothing more than a very brisk and violent motion, which, by means of the air and other transparent media, is conveyed to the eye exactly as the shock through the walking-stick reaches the hand of a blind man. This is instantaneous, and would be so even if the intervening distance were greater than that between earth and heaven. It is therefore no more necessary that anything material should reach the eye from the luminous object than that something should be sent from the ground to the hand of the blind man when he is conscious of the shock of his staff." The celebrated Robert Hooke first threw doubt upon this notion of Descartes, but afterwards substantially espoused it. The belief in instantaneous transmission was destroyed by the discovery of Römer [of the measurable velocity of light].—TYNDALL *Lectures on Light*, lect. 2, p. 44. (A., 1898.)

1181. FACT SURPASSES THEORY—*Life in Torrid Heat and Arctic Cold—Life in Other Worlds.*—For instance, if we did

not know that the torrid zone was inhabited, and could not visit that region, but knew nevertheless how tremendous the heat is there, how short the interval from greatest to least heat, and so on, how ready we should be to believe that neither animal nor vegetable life can exist there. And in like manner as to the arctic regions. Supposing we knew only that there are parts of the earth where the sun is sometimes unseen for several successive weeks, and sometimes remains without setting for as long a period, while even in the heart of summer a cold more intense than our bitterest winters prevails, how startling would be the thought (familiar tho it now seems to us) that there are not only living creatures in the arctic regions, but that a race of men exists and thrives there, even preferring their strange abode to the temperate regions which seem to us so much more pleasant! —PROCTOR *Expanse of Heaven*, p. 51. (L. G. & Co., 1897.)

1182. FACTS AND THEORIES OF SCIENCE TO BE DISCRIMINATED—In every physical science we have carefully to distinguish between the facts which form its subject-matter and the theories by which we attempt to explain these facts and group them in our scientific systems. The first alone can be regarded as absolute knowledge, and such knowledge is immutable, except in so far as subsequent observation may correct previous error. The last are, at best, only guesses at truth, and, even in their highest development, are subject to limitations and liable to change.—COOKE *The New Chemistry*, lect. 1, p. 1. (A., 1899.)

1183. FACTS, DEALING WITH, DISPELS ILLUSIONS—*Life Real and Earnest.*—Provided that he remains undisturbed in his study, the purely theoretical inquirer may smile with calm contempt when, for a time, vanity and conceit seek to swell themselves in science and stir up a commotion. Or he may consider ancient prejudices to be interesting and pardonable, as remains of poetic romance or of youthful enthusiasm. To one who has to contend with the hostile forces of fact, indifference and romance disappear; that which he knows and can do is exposed to severe tests; he can only use the hard and clear light of facts, and must give up the notion of lulling himself in agreeable illusions.—HELMHOLTZ *Popular Lectures*, lect. 5, p. 203. (L. G. & Co., 1898.)

1184. FACTS MAY BE TESTED ONE BY ONE—*A Hypothesis Must Stand or Fall as a Whole—Hence Intolerance of Comprehensive Systems.*—One characteristic of the schools which built up their system on such hypotheses, which they assumed as dogmas, is the intolerance of expression which I have already partially mentioned. One who works upon a well-ascertained foundation may readily admit an error; he loses, by so doing, nothing more than that in which he erred. If, however, the starting-point has been placed upon a hypothesis which either appears guaranteed by authority or is only chosen because it agrees with that which it is wished to believe true, any crack may then hopelessly destroy the whole fabric of conviction. The convinced disciples must therefore claim for each individual part of such a fabric the same degree of infallibility; for the anatomy of Hippocrates just as much as for fever crises; every opponent must only appear then as stupid or depraved, and the dispute will thus, according to old precedent, be so much the more passionate and personal, the more uncertain is the basis which is defended. We have frequent opportunities of confirming these general rules in the schools of dogmatic deductive medicine.—HELMHOLTZ *Popular Lectures*, lect. 5, p. 213. (L. G. & Co., 1898.)

1185. FACTS OF EXTERNAL WORLD CORRECTIVE OF ILLUSIONS—*Resolution Can Hold the Mind to Realities.*—However irresistible our sense-illusions may be, so long as we are under the sway of particular impressions or mental images, we can, when resolved to do so, undeceive ourselves by carefully attending to the actual state of things about us. And in many cases, when once the correction is made, the illusion seems an impossibility. By no effort of imagination are we able to throw ourselves back into the illusory mental condition. So long as this power of dispelling the illusion remains with us, we need not be alarmed at the number and variety of the momentary misapprehensions to which we are liable.—SULLY *Illusions*, ch. 6, p. 125. (A., 1897.)

1186. FACTS OF PAST IN FRAME OF PRESENT—*Memory's Unconscious Coloring.*—We tend to project our present modes of experience into the past. We paint our past in the hues of the present. Thus we imagine that things which impressed us in some remote period of life must answer to what is impressive in our present stage of mental development. For example, a person recalls a hill near the home of his childhood, and has the conviction that it was of great height. On revisiting the place he finds that the eminence is quite insignificant. How can we account for this? For one thing, it is to be observed that to his undeveloped childish muscles the climbing to the top meant a considerable expenditure of energy, to be followed by a sense of fatigue. The man remembers these feelings, and "unconsciously reasoning" by present experience, that is to say, by the amount of walking which would now produce this sense of fatigue, imagines that the height was vastly greater than it really was. Another reason is, of course, that a wider knowledge of mountains has resulted in a great alteration of the man's standard of height.—SULLY *Illusions*, ch. 10, p. 268. (A., 1897.)

1187. FACTS OF SCIENCE NOT TO BE FEARED—*All Real Knowledge Increases Reverence—Gives Higher Conceptions of the Creator's Power and Wisdom.*—It is certainly a legitimate exercise of the powers given to man to follow out those paths, whether well marked or as yet little trodden, which seem likely to lead to new knowledge. We need not be troubled by doubts as to the way in which such paths may lead us, so that they really lead to the recognition of facts. We may learn many things inconsistent, perchance, with our present ideas as to the way in which it has pleased the Almighty to provide for his worlds. We may have to abandon some conceptions which had appeared very accordant with the might and wisdom of the Creator. But we may be sure of this, that whatever new ideas we may legitimately be led to will prove not less worthy of him. Increase of knowledge of his universe—whether of its various parts or of the various periods of its history—will enhance our conceptions of his power and wisdom, though still leaving those conceptions infinitely poor and feeble compared with the reality.—PROCTOR *Expanse of Heaven*, p. 174. (L. G. & Co., 1897.)

1188. FACULTIES UNUSED, BUT PERSISTENT—*Opossum on Treeless Plains.*—It is indeed strange to find this animal [the opossum] on the pampas. . . . It shuffles along slowly and awkwardly on the ground, but is a great traveler nevertheless. . . . In every way it is adapted to an arboreal life, yet it is everywhere found on the level country, far removed from the conditions which one would imagine to be necessary to its existence. For how many thousands of years has this marsupial been a dweller on the plain, all its best faculties unexercised, its beautiful grasping hands pressed to the ground, and its prehensile tail dragged like an idle rope behind it! Yet, if one is brought to a tree, it will take to it as readily as a duck to water or an armadillo to earth, climbing up the trunk and about the branches with a monkey-like agility. How reluctant Nature seems in some cases to undo her own work! How long she will allow a specialized organ, with the correlated instinct, to rest without use, yet ready to flash forth on the instant, bright and keen-edged, as in the ancient days of strife, ages past, before peace came to dwell on earth!—HUDSON *Naturalist in La Plata*, ch. 1, p. 18. (C. & H., 1895.)

1189. FAILURE ACCOMPANYING DEVELOPMENT—*Child's "Common Sense" Declining at Maturity.*—It may often be noticed that children display a power of bringing "common sense" to bear upon the ordinary affairs of life, which seems much beyond that of their elders; and yet a very sensible child will often grow into a much less sensible man. Now the reason of this seems to be that the child perceives the application of "self-evident" considerations to the case at issue, without being embarrassed by a number of other considerations (perhaps of a trivial or conventional nature) which distract the attention and unduly influence the judgment of the adult. And the deliverances of a child's "common sense" thus often resemble those of the old "court fools" or "jesters," whose function seems to have been to speak out "home truths" which timid courtiers would not venture to utter. Moreover, as has been well remarked, "it is quite possible for minds of limited power to manage a small range of experience much better than a large, to get confused (as it were) with resources on too great a scale, and therefore to show far more common sense within the comparatively limited field of childish experience than in the greater world of society or public life. This is probably the explanation of a thing often seen—how very sagacious people instinctively shrink from a field which their tact tells them is too large for them to manage, and keep to one where they are really supreme."—CARPENTER *Mental Physiology*, bk. ii, ch. 11, § 383, p. 477. (A., 1900.)

1190. FAILURE OF MEMORY THROUGH INATTENTION—*Common Facts Not Noted by Consciousness—Names Help Recollection.*—I was taking a walk with a relation who was very much interested in botany and anxious to know the names of the different trees and plants. So I went up an avenue (where nearly every second tree was a plane-tree), and pointed out the various trees and shrubs, mentioning their names, but taking no notice of the plane-trees. I then turned into a side avenue of a similar character, and, having reached the center of it, stopped in front of a plane-tree, and asked, "Have you ever seen a similar tree to that before?" and received the answer I expected: "No, I think that must be a very rare tree. I don't remember ever having seen one like it before." We were in sight of two or three dozen at the time, and the great surprise expressed at finding every other tree a plane was amusing.

The reason I chose a plane-tree was that very few people know a plane-tree, and so that great combiner of impressions, a name, was absent.—ELDRIDGE-GREEN *Memory and Its Cultivation*, pt. i, ch. 7, p. 147. (A., 1900.)

1191. FAILURE OF PAST HYPOTHESES—*A Warning for the Present—Molecular Physics—The Atomic Theory.*—In reference to atoms in molecular physics, Sir W. Thomson says, with much weight, that their assumption can explain no property of the body which has not previously been attributed to the atoms. Whilst assenting to this opinion, I would in no way express myself against the existence of atoms, but only against the endeavor to deduce the principles of theoretical physics from purely

hypothetical assumptions as to the atomic structure of bodies. We now know that many of these hypotheses, which found favor in their day, far overshot the mark.—HELMHOLTZ *Popular Lectures*, lect. 1, p. 17. (L. G. & Co., 1898.)

1192. FAILURE THROUGH LACK OF WILL—*Dreamy Irresolution of Coleridge.*—There was probably no man of his time, or perhaps of any time, who surpassed Coleridge in the combination of the reasoning powers of the philosopher with the imagination of the poet and the inspiration of the seer; and there was perhaps not one of the last generation who has left so strong an impress of himself in the subsequent course of thought of reflective minds engaged in the highest subjects of human contemplation. And yet there was probably never a man endowed with such remarkable gifts who accomplished so little that was worthy of them—the great defect of his character being the want of will to turn his gifts to account; so that, with numerous gigantic projects constantly floating in his mind, he never brought himself even seriously to attempt to execute any one of them. It used to be said of him that whenever either natural obligation or voluntary undertaking made it his duty to do anything, the fact seemed a sufficient reason for his not doing it. Thus, at the very outset of his career, when he had found a bookseller (Mr. Cottle) generous enough to promise him thirty guineas for poems which he recited to him, and might have received the whole sum immediately on delivering the manuscript, he went on, week after week, begging and borrowing for his daily needs in the most humiliating manner, until he had drawn from his patron the whole of the promised purchase-money, without supplying him with a line of that poetry which he had only to write down to free himself from obligation. —The habit of recourse to nervine stimulants (alcohol and opium) which he early formed, and from which he never seemed able to free himself, doubtless still further weakened his power of volitional self-control; so that it became necessary for his welfare that he should yield himself to the control of others.—CARPENTER *Mental Physiology*, bk. i, ch. 6, p. 266. (A., 1900.)

1193. FAILURES PAVE THE WAY TO SUCCESS—I mention these failures [of first attempts to gage depth of glaciers] because they give some idea of the discouragements and difficulties which meet the investigator in any new field of research. The student must remember, for his consolation under such disappointments, that his failures are almost as important to the cause of science and to those who follow him in the same road, as his successes. It is much to know what we *cannot* do in any given direction—the first step, indeed, toward the accomplishment of what we *can* do.—AGASSIZ *Geological Sketches*, ser. i, ch. 8, p. 295. (H. M. & Co., 1896.)

1194. FAINTNESS OF IMPRESSION SUGGESTS DISTANCE IN TIME—There is an opposite effect in the case of recent occurrences that, for some reason or another, have left but a faint impression on the memory, tho this fact is not, perhaps, so familiar as the other. I met a friend, we will suppose, a few days since at my club, and we exchanged a few words. My mind was somewhat preoccupied at the time, and the occurrence did not stamp itself on my recollection. To-day I meet him again, and he reminds me of a promise I made him at the time. His reminder suffices to restore a dim image of the incident, but the fact of its dimness leads to the illusion that it really happened much longer ago, and it is only on my friend's strong assurances, and on reasoning from other data that it must have occurred the day he mentions, that I am able to dismiss the illusion.—SULLY *Illusions*, ch. 10, p. 258. (A., 1897.)

1195. FAITH OF SCIENCE—*Assumptions of Psychology.*—Every natural science assumes certain data uncritically, and declines to challenge the elements between which its own "laws" obtain, and from which its own deductions are carried on. Psychology, the science of finite individual minds, assumes as its data (1) thoughts and feelings, and (2) a physical world in time and space with which they coexist and which (3) they know.—JAMES *Psychology*, vol. i, pref., p. 5. (H. H. & Co., 1899.)

1196. FAITH, SCIENCE FOUNDED ON—*The First Law of Motion—Not One Instance of Its Operation Ever Known.*—The law is, that all motion is in itself (that is to say, except as affected by extraneous forces) uniform in velocity and rectilinear in direction. Thus according to this law a body moving, and not subject to any extraneous force, would go on moving forever at the same rate of velocity and in an exactly straight line.

Now, there is no such motion as this existing on the earth or in the heavens. It is an abstract idea of motion which no man has ever, or can ever, see exemplified. Yet a clear apprehension of this abstract idea was necessary to a right understanding and to the true explanation of all the motions which are actually seen. It was long before this idea was arrived at. There was a real difficulty in conceiving it, because not only is there no such motion in Nature, but there is no possibility by artificial means of producing it. It is impossible to release any moving body from the impulses of extraneous force. The first law of motion is therefore a purely abstract idea. It represents a rule which never operates as we conceive it in itself, but is always complicated with other rules which produce a corresponding complication in result. Like many other laws of the same class, it was discovered,

not by looking outward, but by looking inward; not by observing, but by thinking.—ARGYLL *Reign of Law*, ch. 2, p. 65. (Burt.)

1197. FAITH, SCIENCE TEACHES NEED OF—*Our System but a Corner of Space—All History but a Moment of Time.*—How, then, are we to view the startling fact thus brought before us? Must we admit that so much of the Creator's work is vain in truth as in appearance? or, on the other hand, must we reject the evidence of science? As it seems to me, we need do neither one nor the other. We have before us a great mystery; but it is not a new thing to find the ways of God unsearchable by man. Our faith in the wisdom of God need not be shaken unless we assume that our science teaches us the whole of that which is. But inasmuch as science itself has taught us over and over again how little we really know, how little we can know, I think that we may very well believe in this instance that the seeming mystery arises from the imperfectness of our knowledge. If we could see the whole plan of the Creator, instead of the minutest portion; if we could scan the whole of space, instead of the merest corner; if all time were before us, instead of a span—we might pronounce judgment. As it is, what, after all, has science taught us but what we had already learned? "The judgments of God are unsearchable, and his ways past finding out" (Rom. xi. 33; 1 Cor. xiii, 12).—PROCTOR *Our Place among Infinities*, p. 43. (L. G. & Co., 1897.)

1198. FAITHFULNESS THROUGH ALL THINGS—*The Magnetic Needle—Wonderful Power of Magnetism.*—This study of the magnetism of our wandering planet is very interesting, and one which is still very little known. Here is a weak needle, a slip of magnetic iron, which with its restless and agitated finger incessantly seeks a region near the north. Carry this needle in a balloon up to the higher aerial regions, where human life begins to be extinguished; shut it up in a tomb closely separated from the light of day; take it down into the pit of a mine, to more than a thousand yards in depth, and incessantly, day and night, without fatigue and without rest, it watches, trembles, throbs, seeks the point which attracts it across the sky, through the earth, and through the night.—FLAMMARION *Popular Astronomy*, bk. iii, ch. 5, p. 289. (A.)

1199. FAMILY AND HOME PART OF SELF—*The Broadening of Individual Life.*—Our immediate family is a part of ourselves. Our father and mother, our wife and babes, are bone of our bone and flesh of our flesh. When they die, a part of our very selves is gone. If they do anything wrong, it is our shame. If they are insulted, our anger flashes forth as readily as if we stood in their place. Our home comes next. Its scenes are part of our life; its aspects awaken the tenderest feelings of affection; and we do not easily forgive the stranger who, in visiting it, finds fault with its arrangements or treats it with contempt. All these different things are the objects of instinctive preferences coupled with the most important practical interests of life.—JAMES *Psychology*, vol. i, ch. 10, p. 292. (H. H. & Co., 1899.)

1200. FAMILY THE EDUCATOR OF MANKIND—*Love and Righteousness.*—Looking at the mere dynamics of the question, the family contains all the machinery and nearly all the power for the moral education of mankind. Feebly, but adequately, in the early chapters of man's history, it fulfilled its function of nursing love, the mother of all morality; and righteousness, the father of all morality, so preparing a parentage for all the beautiful spiritual children which in later years should spring from them. If life henceforth is to go on at all, it must be a better life, a more loving life, a more abundant life; and this premium upon love means—if it means anything—that evolution is taking henceforth an ethical direction.—DRUMMOND *Ascent of Man*, ch. 9, p. 316. (J. P., 1900.)

1201. FAMILY THE FOUNDATION OF SOCIAL PROGRESS—*The Masterpiece of Evolution.*—If the crowning work of organic evolution is the mammalia, the consummation of the mammalia is the family. Physically, psychically, ethically, the family is the masterpiece of evolution. The creation of evolution, it was destined to become the most active instrument and ally which evolution has ever had. For what is its evolutionary significance? It is the generator and the repository of the forces which alone can carry out the social and moral progress of the world. There they rally when they become enfeebled, there their excesses are counterbalanced, and thence they radiate out, refined and reenforced, to do their holy work.—DRUMMOND *Ascent of Man*, ch. 9, p. 316. (J. P., 1900.)

1202. FAMILY, THE HUMAN, ENDURES THROUGHOUT THE YEAR—*Advance from Conditions of Lower Animals.*—But when man's evolution made a certain progress, and when the mother's care reached mature perfection, it was no longer imperative for children to be born only when the sun was shining and the fruits grew ripe. The parents could now make provision for any weather and for any dearth. They could give their little ones clothes when nights grew cold; they could build barns and granaries against times of famine. In any climate, and at any time, their young were safe; and the old marriage dates, with their subsequent desertions, were struck from the human calendar. So arose, or at least was inaugurated, family life, the first and the last nursery of the higher sympathies, and the home of all that was afterwards holy in the world. One could not

find a simpler instance of the growing sovereignty of mind over the powers of Nature. So remote a cause as the inclination of the earth's axis, and the consequent changes of the seasons, determines the time of marriage for almost the whole animal creation, while man, and a few other forms of life whose environment is exceptional, are able to refuse all such dictations. It was when man's mind became capable of making its own provisions against the weather and the crops that the possibilities of fatherhood, motherhood, and the family were realized.—DRUMMOND *Ascent of Man*, ch. 9, p. 298. (J. P., 1900.)

1203. FAMILY THE UNIT OF SOCIETY—*Lengthened Infancy the Bond of Home Life.*—The primordial unit of human society is the family, and it was by the establishment of definite and permanent family relationships that the step was taken which raised man socially above the level of gregarious apehood. This great point was attained through that lengthening of the period of helpless childhood which accompanied the gradually increasing intelligence of our half-human ancestors. When childhood had come to extend over a period of ten or a dozen years—a period which would be doubled, or more than doubled, where several children were born in succession to the same parents—the relationships between father and mother, brethren and sisters, must have become firmly knit; and thus the family, the unit of human society, gradually came into existence.—FISKE *Destiny of Man*, ch. 9, p. 67. (H. M. & Co., 1900.)

1204. FAMINE, RESOURCE AGAINST—*Aphid-life Concurrent with Ant-life in Winter.*—[Ants] are benumbed in the great cold, but when the season is not too rigorous the depth of their nest places them out of reach of the frost. I have seen them pacing about on the snow and pursuing their habits at this temperature. They would be exposed to the horrors of famine if they did not have resources against such a contingency whenever they are not benumbed, and these resources are no other than the plant-lice, which, by an admirable concurrence of circumstances that we cannot attribute to chance, fall into lethargy at the same degree of cold as the ants and are revived at the same time as they; this the ants always recognize whenever they have need of food.—HUBER *Recherches sur les Mœurs des Fourmis indigènes*, p. 202. (Translated for *Scientific Side-Lights.)*

1205. ——— *Hunting of Aphids When These Are Not Domesticated.*—Those ants that do not know how to collect these useful insects into their own habitations, at least know their retreats, following them to the foot of trees, or upon the roots of shrubs formerly frequented at the first, then darting along the hedges, following the path that will conduct them to their supplies, and carrying back to the republic a little of the honey-colored food, for in winter it requires very little to maintain them.—HUBER *Recherches sur les Mœurs des Fourmis indigènes*, p. 202. (Translated for *Scientific Side-Lights.)*

1206. FARMING OF INSECTS—*The Harvesting-ants—Their Providence and Industry.*—A Texan ant, *Pogonomymex barbatus*, is a harvesting species, storing up especially the grains of *Aristida oligantha*, the so-called "ant-rice," and of a grass, *Buchloe dactyloides*. These ants clear disks, ten or twelve feet in diameter, round the entrance to their nest, a work of no small labor in the rich soil and under the hot sun of Texas. I say "clear disks," but some, tho not all, of these disks are occupied, especially round the edge, by a growth of ant-rice. These ants were first noticed by Mr. Buckley [*Proc. Acad. Nat. Sci.*, Philadelphia, 1860], and their habits were some time afterwards described in more detail by Dr. Lincecum [*Linnean Journal*, 1861, p. 29], who maintained not only that the ground was carefully cleared of all other species of plants, but that this grass was intentionally cultivated by the ants. Mr. McCook ["The Nat. Hist. of the Agricultural Ants of Texas," p. 38], by whom this subject has been recently studied, fully confirms Dr. Lincecum that the disks are kept carefully clean, that the ant-rice alone is permitted to grow on them, and that the produce of this crop is carefully harvested; but he thinks that the ant-rice sows itself, and is not actually cultivated by the ants. I have myself observed in Algeria that certain species of plants are allowed by the ants to grow on their nests.—AVEBURY *Ants, Bees, and Wasps*, ch. 3, p. 61. (A., 1900.)

1207. FASCINATION OF FLAME—*Infant and Insect Alike Attracted—Experience Has Taught Man Caution.*—A brilliant flame is the first object to fix the gaze of the young infant; and in manhood we still continue to feel a strange fascination under the influence of the same phenomenon. Even phosphorescence, unaccompanied as it is by flame, has an irresistible charm for us; while the vivid combustion of inflammable matter embodies a power and impetuosity which rivet the attention of the most stolid observer. We smile at the stupidity of the moth that singes its wings in the candle-flame; but there is within us a similar mysterious impulse that would impel us into the burning mass but for the consciousness of resulting injury, derived solely, as metaphysicians tell us, from knowledge gained by experience.—LOWE *Nature-Studies*, p. 1. (Hum., 1888.)

1208. ——— *Lighthouse a Beacon of Death—Birds of Passage Allured to Destruction.*—The keeper of the lighthouse at Atlantic City describes the migratory birds as following the New Jersey coast all the way up and down in their flights. At

night they fly high, and when they see Absecon Inlet light, which is 167 feet above the ground, they head directly for it. They seem to be attracted in the same way that the moths which flicker around a candle are. If carried along by a heavy wind, they dart against the plate-glass windows surrounding the lens, and drop to the ground dead, bespattering the panes with their blood, to prevent which a wire netting has been constructed on the north and south sides of the lantern. Not long ago a large duck, which was sailing along in a furious storm, was dashed against this netting with such force as to indent it six square inches. When the weather is clear immense numbers of small birds hover about the light after dark, and then, as soon as they have rested on the rail surrounding it, fly off, but soon return again. A large snipe landed so violently against the wirework that he plunged through one of the meshes and stripped himself of all his feathers as far back as the shoulders.—BROWN *Nature-Studies*, p. 13. (Hum., 1888.)

1209. FATALISM, FAILURE OF, INEVITABLE—*Impulse To Take Life Strivingly Is Indestructible.*—Nothing could be more absurd than to hope for the definitive triumph of any philosophy which should refuse to legitimate, and to legitimate in an emphatic manner, the more powerful of our emotional and practical tendencies. Fatalism, whose solving word in all crises of behavior is "All striving is vain," will never reign supreme, for the impulse to take life strivingly is indestructible in the race. Moral creeds which speak to that impulse will be widely successful in spite of inconsistency, vagueness, and shadowy determination of expectancy. Man needs a rule for his will, and will invent one if one be not given him.—JAMES *Psychology*, vol. ii, ch. 21, p. 315. (H. H. & Co., 1899.)

1210. FATHERHOOD ESSENTIAL TO FAMILY LIFE—*The Goal of Evolution.*—Now here is a very pretty problem for evolution. She has at once to make good husbands and good fathers out of lawless savages. Unless this problem is solved the higher progress of the world is at an end. It is the mature opinion of every one who has thought upon the history of the world, that the thing of highest importance for all times and to all nations is family life. When the family was instituted, and not till then, the higher evolution of the world was secured. Hence the exceptional value of the father's development. As the other half of the arch on which the whole higher world is built, his taming, his domestication, his moral discipline, are vital; and in the nature of things this was the next great operation undertaken by evolution.—DRUMMOND *Ascent of Man*, p. 295. (J. P., 1900.)

1211. FATHERHOOD OF GOD—*Primitive Conception of Deity as Recorded in the Vedas—A Descending Evolution Thence.*—One of the most remarkable schools of Christian thought which has arisen in recent times is that which has made the idea of the "Fatherhood of God" the basis of its distinctive teaching. Yet it is nothing but a reversion to the simplest of all ideas, the most rudimentary of all experiences—that which takes the functions and the authority of a father as the most natural image of the invisible and infinite being to whom we owe "life and breath and all things." In the facts of Vedic literature, as now sifted and presented to us by scholars, when we carefully separate these facts from theories about them, there is really no symptom of any time when the idea of some living being in the nature of God had not yet been attained. On the contrary, the earliest indications of this conception are indications of the sublimest character, and the process of evolution seems distinctly to have been a process, not of an ascending, but of a descending order. Thus it appears that the great appellative "Dyaus," which in the earliest Vedic literature is masculine and stood for "the Bright or Shining One," or the Living Being whose dwelling is the light, had in later times become a feminine and stood for nothing but the sky.—ARGYLL *Unity of Nature*, ch. 12, p. 302. (Burt.)

1212. ——— ——— *Sublimity of Early Conceptions—A Personal God Addressed in the Vedas.*—It is quite evident that in the oldest times of the Aryan race, in so far as those times have left us any record, not only had the idea of a personal God been fully conceived, but such a being had been described and addressed in language and under symbols which are comparable with the sublimest imagery in the visions of Patmos. How firmly, too, and how naturally these conceptions of a God were rooted in the analogies of our own human personality is attested by the additional fact that paternity was the earliest Vedic idea of creation, and Dyaus was invoked not only as the heaven-father, but specially as the "Dyaush pitâ ganitâ," which is the Sanskrit equivalent of the Greek Ζεὺς πατὴρ γενετήρ [Zeus, the All-producing Father].—ARGYLL *Unity of Nature*, ch. 12, p. 302. (Burt.)

1213. FAUNA, RANGE OF, DETERMINED BY CLIMATE—*Arctic, Temperate, and Tropical Varieties—Buffalo, Opossum, Raccoon.*—The predominant influence of climate over all the other causes which limit the range of species in the mammalia is perhaps nowhere so conspicuously displayed as in North America. The arctic fauna, so admirably described by Sir John Richardson, has scarcely any species in common with the fauna of the State of New York, which is 600 miles farther south, and comprises about forty distinct mammifers. If again we travel farther south about 600 miles, and enter another zone, running east and west, in South Carolina, Georgia, Alabama, and the contiguous States, we again meet with a

new assemblage of land quadrupeds, and this again differs from the fauna of Texas, where frosts are unknown. It will be observed that on this continent there are no great geographical barriers running east and west, such as high snow-clad mountains, barren deserts, or wide arms of the sea, capable of checking the free migration of species from north to south. But notwithstanding the distinctness of those zones of indigenous mammalia, there are some species, such as the buffalo *(Bison americanus)*, the raccoon *(Procyon lotor)*, and the Virginian opossum *(Didelphys virginiana)*, which have a wider habitation, ranging almost from Canada to the Gulf of Mexico; but they form exceptions to the general rule. The opossum of Texas *(Didelphys carnivora)* is different from that of Virginia, and other species of the same genus inhabit westward of the Rocky Mountains, in California, for example, where almost all the mammalia differ from those of the United States.—LYELL *Principles of Geology*, bk. iii, ch. 37, p. 634. (A., 1854.)

1214. FEAR OF MAN AMONG ANIMALS—*An Acquired Propensity.*—We learn from Mr. Darwin that in the Galapagos archipelago, placed directly under the equator, and nearly 600 miles west of the American continent, all the terrestrial birds, as the finches, doves, hawks, and others, are so tame that they may be killed with a switch. One day, says this author, "a mocking-bird alighted on the edge of a pitcher which I held in my hand, and began quietly to sip the water, and allowed me to lift it with the vessel from the ground." Yet formerly, when the first Europeans landed, and found no inhabitants in these islands, the birds were even tamer than now: already they are beginning to acquire that salutary dread of man which in countries long settled is natural even to young birds which have never received any injury. So in the Falkland Islands, both the birds and foxes are entirely without fear of man; whereas, in the adjoining mainland of South America, many of the same species of birds are extremely wild: for there they have for ages been persecuted by the natives.

Dr. Richardson informs us, in his able history of the habits of the North American animals, that, "in the retired parts of the mountains where the hunters had seldom penetrated, there is no difficulty in approaching the Rocky Mountain sheep, which there exhibit the simplicity of character so remarkable in the domestic species; but where they have been often fired at they are exceedingly wild, alarm their companions on the approach of danger by a hissing noise, and scale the rocks with a speed and agility that baffle pursuit."—LYELL *Principles of Geology*, bk. iii, ch. 35, p. 597. (A., 1854.)

1215. FEAR TAUGHT BY PARENT BIRD—*Young in Shell Know Warning Cry.*—This fear caused by the parent bird's warning note begins to manifest itself even before the young are hatched—and my observations on this point refer to several species in three widely separated orders. When the little prisoner is hammering at its shell, and uttering its feeble peep, as if begging to be let out, if the warning note is uttered, even at a considerable distance, the strokes and complaining instantly cease, and the chick will then remain quiescent in the shell for a long time, or until the parent, by a changed note, conveys to it an intimation that the danger is over.—HUDSON *Naturalist in La Plata*, ch. 5, p. 90. (C. & H., 1895.)

1216. FEAR WITHOUT REASON—*Stage-fright and Shyness.*—Both stage-fright and servile terror may exist with the most indefinite apprehensions of danger, and, in fact, when our reason tells us there is no occasion for alarm. We must, therefore, admit a certain amount of purely instinctive perturbation and constraint, due to the consciousness that we have become objects for other people's eyes. Mr. Darwin goes on to say: "Shyness comes on at a very early age. In one of my own children, two years and three months old, I saw a trace of what certainly appeared to be shyness directed toward myself, after an absence from home of only a week." Every parent has noticed the same sort of thing. Considering the despotic powers of rulers in savage tribes, respect and awe must, from time immemorial, have been emotions excited by certain individuals; and stage-fright, servile terror, and shyness must have had as copious opportunities for exercise as at the present time. Whether these impulses could ever have been useful, and selected for usefulness, is a question which, it would seem, can only be answered in the negative. Apparently they are pure hindrances, like fainting at sight of blood or disease, seasickness, a dizzy head on high places, and certain squeamishnesses of esthetic taste. They are incidental emotions, in spite of which we get along.—JAMES *Psychology*, vol. ii, ch. 24, p. 432. (H. H. & Co., 1899.)

1217. FEELING A SUM OF EXPERIENCES—Experience is remolding us every moment, and our mental reaction on every given thing is really a resultant of our experience of the whole world up to that date.—JAMES *Psychology*, vol. i, ch. 9, p. 234. (H. H. & Co., 1899.)

1218. FEELING, THE DOMINANT—*Molds Images in Dreams.*—The analogy of feeling is a common link between dream-images. Now, if any shade of feeling becomes fixed and dominant in the mind, it will tend to control all the images of the time, allowing certain congruous ones to enter and excluding others. If, for example, a feeling of distress occupies the mind, distressing images will have the advantage in the struggle for existence which

goes on in the world of mind as well as in that of matter. We may say that attention, which is here wholly a passive process, is controlled by the emotion of the time, and bent in the direction of congruent or harmonious images.—SULLY *Illusions*, ch. 7, p. 164. (A., 1897.)

1219. FEELINGS MANIFESTED BY EXPRESSION AND ATTITUDE—*Art Recognizes Bodily Manifestation of Spiritual Attributes.*—The interest of the human presence, in all its various workings, regarded as symptomatic of mental processes, is laid hold of and heightened in the fine art of cultivated nations. To the painter, the sculptor, and the poet, every feeling has its appropriate manifestation. Not merely are the grosser forms of feeling thus linked with material adjuncts; in the artist's view, the loftiest, the noblest, the holiest of the human emotions have their marked and inseparable attitude and deportment. In the artistic conceptions of the Middle Ages, more especially, the most divine attributes of the immaterial soul had their counterpart in the material body: the martyr, the saint, the Blessed Virgin, the Savior himself, manifested their glorious nature by the sympathetic movements of the mortal framework. So far as concerns the entire compass of our feelings or emotions, it is the universal testimony of mankind that these have no independent spiritual subsistence, but are in every case embodied in our fleshly form. This very strong and patent fact has been usually kept out of view in the multifarious discussions respecting the immaterial soul. Apparent as it is to the vulgar, and intently studied as it has been by the sculptor, the painter, and the poet, it has been disregarded both by metaphysicians and by theologians when engaged in settling the boundaries of mind and body.—BAIN *Mind and Body*, ch. 2, p. 3. (Hum., 1880.)

1220. FEINT OF MONKEY—*Pretense of Throwing Things at Enemy.*—When he is angry, and has at hand only those things which he wishes to keep, he makes a great show of throwing them at people, but always retains a hold. Thus if he has had a plaything a long time and is tired of it, he throws it right at a person without the least hesitation; but if he has a new thing which he values, he goes through all the appropriate motions for throwing, but only brings the object down with a noise upon the ground, taking care not to let go his hold.—ROMANES *Animal Intelligence* [extract from diary of author's sister], ch. 17, p. 493. (A., 1899.)

1221. FERMENTATION THE PRODUCT OF LIVING ORGANISMS—*Fermentation Involves a Breaking-down of Complex Bodies.*—We may now return to the work of Pasteur and the question of organized ferments [omitting unorganized ferments like the pepsin of the gastric juice]. Let us preface further remark with an axiom with which Professor Frankland sums up the vitalistic theory of fermentation, which was supported by the researches of Pasteur: "No fermentation without organisms; in every fermentation a particular organism." From these words we gather that there is no one particular organism or vegetable cell to be designated the micro-organism of fermentation, but that there are a number of fermentations each started by some specific form of agent. It is true that the chemical changes induced by organized ferments depend on the life-processes of micro-organisms which feed upon the sugar or other substance in solution, and excrete the product of the fermentation. Fermentation nearly always consists of a process of breaking-down of complex bodies, like sugar, into simpler ones, like alcohol and carbonic acid. —NEWMAN *Bacteria*, ch. 4, p. 115. (G. P. P., 1899.)

1222. FERMENTS IN THE DAIRY—*Inoculation of Cream—Choice Bacilli Preserved and Indefinitely Multiplied—Science Gives New Meaning to the Parable of the Leaven.*—The so-called ripening of cream and of cheese consists solely in the development of active ferments and in the results of the oxidation which they produce. In a successful dairy the ferments which are favorable to the production of the best quality of cream and cheese are alone allowed to act. In a poorly kept dairy every kind of a ferment is allowed to grow at will, and the results of such a slipshod method of control are shown in the bad character of the cheese and the rancid flavor of the butter which are produced. The development of the theory of fermentation, and its application to so many practical purposes, led chemists to investigate the character of the organisms which were found to be active in the dairy. These studies led speedily to the isolation of the ferments of a favorable nature, and to methods of destroying those which produced undesirable products. At the present day we find realized that condition of affairs which I have just alluded to as possible in the future of the fertilization of the soil. A bacillus which is capable of exciting the very best character of fermentation in cream has already been prepared in a pure state and can be delivered to the practical dairymen of the country. This minute and invisible particle of vital matter, when added to sterilized cream, sets up a fermentation which, in its results, produces the most delicious flavor that the best butter can have. A sample of cream thus inoculated is mixed with large quantities of ordinary cream, thus securing the proper fermentation throughout the whole mass. . . . Portions of these inoculated masses may be kept in cold storage. . . . In this manner a minute drop of liquid containing a few of the bacilli in question may serve to impart to thousands of pounds of butter, made during a considerable period

of time, a most delicious and desirable flavor.—WILEY *Relations of Chemistry to Industrial Progress (Address at Purdue University, Lafayette, Ind., 1896*, p. 40).

1223. FERNS, ANCIENT, PRESERVED IN COAL—*Enduring Record of the Evanescent.*—There can be no doubt as to the true nature of the Carboniferous forests; for the structural character of the trees is as strongly marked in their fossil remains as in any living plants of the same character. We distinguish the ferns not only by the peculiar form of their leaves, often perfectly preserved, but also by the fructification on the lower surface of the leaves, and by the distinct marks made on the stem at their point of juncture with it. The leaf of the fern, when falling, leaves a scar on the stem varying in shape and size according to the kind of fern, so that the botanist readily distinguishes any particular species of fern by this means—a birthmark, as it were, by which he detects the parentage of the individual.—AGASSIZ *Geological Sketches*, ser. i, ch. 3, p. 76. (H. M. & Co., 1896.)

1224. FERTILITY DUE TO MICRO-ORGANISMS—*Vitality of the Soil—Plants Die in Sterilized Earth.*—These organisms have been found to exist in innumerable colonies in the soil. The soil is no longer regarded as dead matter, but in the highest degree as a vital organism. The possibility of growing plants has been found to depend directly upon the activity of the micro-organisms of the soil. The progress of chemistry has thus revealed in a new light the relations which it holds to the very base of society. If the activity of the micro-organisms producing oxidations in the soil were destroyed for a single year, nearly the whole of the animal life of the earth would perish of hunger. Already practical results of immense importance have grown out of these achievements of chemical research. They have profoundly impressed the methods of agriculture and systems of fertilization. If pease or beans be planted in a sterilized soil the growth of the plantlet produced will be limited by the nourishment contained in the seed. After a few days of apparently vigorous evolution, during which time the reserve stores of plant-food in the seeds have been consumed, the young plant will wither and die.—WILEY *Relations of Chemistry to Industrial Progress (Address at Purdue University, Lafayette, Ind., 1896*, p. 36).

1225. FERTILITY OF LAND DETERMINED BY MOUNTAINS—*Their Effect on the Rainfall.*—Imagine a southwest wind blowing across the Atlantic towards Ireland. In its passage it charges itself with aqueous vapor. In the south of Ireland it encounters the mountains of Kerry: the highest of these is Magillicuddy's Reeks, near Kil larney. Now the lowest stratum of this Atlantic wind is that which is most fully charged with vapor. When it encounters the base of the Kerry mountains it is tilted up and flows bodily over them. Its load of vapor is therefore carried to a height, it expands on reaching the height, it is chilled in consequence of the expansion, and comes down in copious showers of rain. From this, in fact, arises the luxuriant vegetation of Killarney; to this, indeed, the lakes owe their water-supply. The cold crests of the mountains also aid in the work of condensation.

Note the consequence. There is a town called Cahirciveen to the southwest of Magillicuddy's Reeks, at which observations of the rainfall have been made, and a good distance farther to the northeast, right in the course of the southwest wind, there is another town, called Portarlington, at which observations of rainfall have also been made. But before the wind reaches the latter station it has passed over the mountains of Kerry and left a great portion of its moisture behind it. What is the result? At Cahirciveen, as shown by Dr. Lloyd, the rainfall amounts to 59 inches in a year, while at Portarlington it is only 21 inches.—TYNDALL *Forms of Water*, § 8, par. 81, p. 27. (A., 1899.)

1226. FERTILITY TURNED TO BARRENNESS—*Land Upheaved across Bed of Stream.*—On the mainland near Lima, and on the neighboring island of San Lorenzo, Mr. Darwin found proofs that the ancient bed of the sea had been raised to the height of more than eighty feet above water within the human epoch, strata having been discovered at that altitude containing pieces of cotton thread and plaited rush, together with seaweed and marine shells. The same author learnt from Mr. Gill, a civil engineer, that he discovered in the interior near Lima, between Casma and Huaraz, the dried-up channel of a large river, sometimes worn through solid rock, which, instead of continually ascending towards its source, has, in one place, a steep downward slope in that direction, for a ridge or line of hills has been uplifted directly across the bed of the stream, which is now arched. By these changes the water has been turned into some other course; and a district, once fertile, and still covered with ruins, and bearing the marks of ancient cultivation, has been converted into a desert.—LYELL *Principles of Geology*, bk. ii, ch. 29, p. 502. (A., 1854.)

1227. FETISHISM, ORIGIN OF IDEA AND NAME—*Hasty Generalizations in Study of Religions.*—Professor Max Müller has done memorable service in the analysis and in the exposure which he has given us of the origin and use of the word "fetishism," and of the theory which represents it as a necessary stage in the development of religion. It turns out that the word itself, and the fundamental idea it embodies, is a word and an idea derived from one of those

popular superstitions which are so common in connection with Latin Christianity. The Portuguese sailors who first explored the West Coast of Africa were themselves accustomed to attach superstitious value to beads, or crosses, or images, or charms, and amulets of their own. These were called "feitiços." They saw the negroes attaching some similar value to various objects of a similar kind, and these Portuguese sailors therefore described the negro worship as the worship of "feitiços." President De Brosses, a French philosopher of the Voltairean epoch in literature, then extended the term "fetish" so as to include not only artificial articles, but also such great natural features as trees, mountains, rivers, and animals. In this way he was enabled to classify together, under one indiscriminate appellation, many different kinds of worship and many different stages in the history of religious development or decay. This is an excellent example of the crude theories and false generalizations which have been prevalent on the subject of the origin of religion. First, there is the assumption that whatever is lowest in savagery must have been primeval—an assumption which is in all cases improbable, and in many cases must necessarily be false. Next there is great carelessness in ascertaining what is really true even of existing savages in respect to their religious beliefs. —ARGYLL *Unity of Nature*, ch. 12, p. 284. (Burt.)

1228. FICTIONS OF LAMARCK—*No Known Instance of Acquisition of New Organs.*—I must here interrupt the author's [Lamarck's] argument, by observing that no positive fact is cited to exemplify the substitution of some entirely new sense, faculty, or organ in the room of some other suppressed as useless. All the instances adduced go only to prove that the dimensions and strength of members and the perfection of certain attributes may, in a long succession of generations, be lessened and enfeebled by disuse; or, on the contrary, be matured and augmented by active exertion; just as we know that the power of scent is feeble in the greyhound, while its swiftness of pace and its acuteness of sight are remarkable—that the harrier and staghound, on the contrary, are comparatively slow in their movements, but excel in the sense of smelling.

It was necessary to point out to the reader this important chasm in the chain of evidence, because he might otherwise imagine that I had merely omitted the illustrations for the sake of brevity: but the plain truth is that there were no examples to be found; and when Lamarck talks "of the efforts of internal sentiment," "the influence of subtle fluids," and "acts of organization," as causes whereby animals and plants may acquire new organs, he substitutes names for things; and, with a disregard to the strict rules of induction, resorts to fictions, as ideal as the "plastic virtue," and other phantoms of the geologists of the Middle Ages.—LYELL *Principles of Geology*, bk. iii, ch. 33, p. 571. (A., 1854.)

1229. FIG, DOMESTIC, IN THE UNITED STATES—*Great Fig-tree of Chico, California.*—Fig-culture has never amounted to much as an industry in this country. Fig-trees grow abundantly throughout the South and in California, having been introduced by the early French and Spanish settlers, and there have been more or less frequent importations since. As a domestic fruit, the fig is of considerable importance in all the Gulf and South Atlantic States. It is a common dooryard tree throughout this region. It has been grown with more or less success as far north as the lower Hudson River Valley, and where well cared for during the winter it will bear well for years, even at these northern limits. In the South figs are used almost entirely for household purposes. They are eaten fresh from the tree and are served on the table with sugar and cream. They are also stewed and made into puddings and pies, and are canned and preserved. In this section figs are occasionally, but seldom, dried for household use, as they ripen at the period of summer showers, which makes drying difficult. Much more of an effort to produce a salable dried fig has been made in California than in the South, especially during the last twenty years, and a greater success has been secured, probably on account of the drier climate. Fig-trees were grown in California by the early Spanish padres, probably as early as 1710, and have flourished throughout the southern part of the State, one of the largest and most remarkable trees in America growing as far north as Chico (130 miles north of San Francisco), on the Bidwell place, where it was planted in 1856.

The writer saw this tree in 1898, and it is certainly one of the great horticultural curiosities of the country. It is 11 feet in circumference near the base of the trunk; branches have grown down into the ground and sent up new shoots, and the process has been repeated until a ground space of 150 feet in diameter is covered by this one tree, giving a dense shade over a space big enough to accommodate a large picnic party. —HOWARD *Smyrna Fig Culture in the United States* (*Year-book of the Department of Agriculture, 1900*, p. 79).

1230. FIG, THE SMYRNA, NATURALIZED IN CALIFORNIA—*Failure of Fruit to Mature—Utility of the Wild Variety, or Caprifig, Discovered.*—After the early attempts to dry figs in California had progressed for some years it was gradually realized that with the varieties then growing it was impossible to arrive at a product which should compare in quality or commercial value with the Smyrna fig of com-

merce. As a result, in 1880 and 1882, Mr. Gulian P. Rixford, of the San Francisco *Bulletin*, imported into California, by the aid of E. F. Smithers, United States Consul at Smyrna, and A. Sida, an American merchant in Smyrna, about 14,000 cuttings of the supposedly best varieties of Smyrna fig-trees. These cuttings were widely distributed and were known as the "*Bulletin*" cuttings. This effort received wide newspaper notoriety, and much was expected of it, but when the trees came into bearing it was found that the fruit invariably dropped on or before reaching the size of a marble. . . .

In 1886 Mr. F. Roeding, a banker in San Francisco and proprietor of the Fancher Creek Nurseries of Fresno, having become convinced that California could be made to grow as good a fig as could be grown in Smyrna, sent his foreman, Mr. W. C. West, to Smyrna for the purpose of investigating the fig industry on the spot. Mr. West remained in Smyrna four months and succeeded in securing several thousand Smyrna fig cuttings, as well as cuttings of wild figs and a few of such varieties as are grown for home consumption. He was watched by the people constantly. He was refused the sale of cuttings, and finally succeeded only by buying through a foreign resident, who was not suspected of any intention to export. After a journey of several months the cuttings arrived in Fresno in good condition and were planted in 1888 in the Fancher Creek Nursery, 20 acres being planted that year, 20 more in 1889, and in 1891 an additional 20 acres.

The importation at this time of the wild, or caprifig, cuttings was the most important step which had yet been taken toward the solution of the problem. This importation was due to the tardy recognition of the fact that the Smyrna fig, the standard fig of commerce, owes its peculiar flavor to the number of ripe seeds which it contains, and that these ripe seeds are only to be gained by the fertilization of the flowers of the Smyrna fig with pollen derived from the wild fig, or caprifig. [This, it was discovered, is effected through the interposition of an insect. See INSECTS.] — HOWARD *Smyrna Fig Culture in the United States (Year-book of the Department of Agriculture, 1900*, p. 80).

1231. FIRE AND BROOM AS TOOLS OF WOMAN—*Primitive Cooking Utensils.*—As soon as the tree was felled, or taking advantage of the wind-giant's sport, [women] burned and hacked off a convenient length of the trunk; then, gathering from the forests a supply of fat pine knots, they burned out the cavity of the future boiler. They carefully watched the progress of the fire, and when it threatened to spread laterally they checked its course in that direction by means of strips of green bark or mud or water. As soon as the ashes and charred wood prevented the further action of the fire, this marvelous Gill-at-all-trades re moved the fire and brushed out the débri with an improvised broom of grass. Then by means of a scraper of flint which she ha made, she dug away the charcoal until sh had exposed a clean surface of wood. Th firing and scraping were repeated until th "dugout" assumed the desired form. Th trough completed, it was ready to do th boiling for the family as soon as the mea could be prepared and the stones heate This apprenticeship of fire in wood-workin calls for woman's help in more industrie than one not strictly her own.—MASO *Woman's Share in Primitive Culture,* ch. 2 p. 32. (A., 1894.)

1232. FIRE AND ITS USES—*Fires o Cave-men in the Mammoth Period—Grea Agency Utilized by Man Alone.*—Man under stands fire and deals with it in ways quit beyond the intelligence of the lower animals There is an old story how, in the forests o equatorial Africa, when travelers had gon away in the morning and left their fire burning, the huge manlike apes called pon gos (probably our gorillas) would come an sit round the burning logs till they wen out, not having the sagacity to lay mor wood on. This story is often repeated to contrast human intelligence with the dul ness of even the highest apes. Of cours there had been forest-fires in ages befor man, as when the trees had been set i flames by lightning or by a lava-stream But of all creatures man alone has know how to manage fire, to carry it from plac to place with burning brands, and when it went out to produce it afresh. No savage tribe seems really to have been found so low as to be without fire. In the limestone caverns, among the relics of the mammoth period, morsels of charcoal and burnt bones are found embedded, which show that even in that remote antiquity the rude cave-men made fires to cook their food and warm themselves by.—TYLOR *Anthropology*, ch. 11, p. 260. (A., 1899.)

1233. FIRE A NECESSITY OF CIVILIZATION—*Once Deified—Primitive Fire-worship.*—Remember now that fire is one of the most valuable servants of mankind; that it is the source of all artificial heat and light; that in the steam-engine it is the apparent origin of that power which animates the commerce and the industry of the civilized world; that under its influence iron becomes plastic, and the ores give up their metallic treasures; that it is, in fine, the agent of all the arts—and you cannot wonder that in a ruder age the Romans should have enthroned its presiding deity on Olympus, or the Persians worshiped its supposed essence as divinity itself.—COOKE *Religion and Chemistry*, ch. 3, p. 84. (A., 1897.)

1234. FIRE ENABLES MAN TO SUBDUE THE EARTH—It is scarcely possible to conceive of man without fire. Very early

in history he discovered the Promethean spark, and a train of blessings came with its advent. The light and warmth of the sun were let into his cheerless dwelling. Forests and jungles, with their poisonous malaria, noxious insects, venomous serpents, and ravening beasts were subdued or quickly removed. Life was prolonged by the cooking of food and by the ability to preserve it for future use through drying, smoking, roasting, etc. In the open the hunter sleeps secure from ravenous beasts so long as his fire is burning.

In old archeological sites in Europe, representing the remains of the cave-men of the Mousterian epoch in France and Belgium, are found flints that have been cracked by fire, fragments of charcoal, burnt bones that have been split for the marrow.—MASON *Origins of Invention,* ch. 3, p. 84. (S., 1899.)

1235. FIRE FROM FLINT AND STEEL —*Progress to Friction Matches, Argand Burner, Gas and Electric Lighting.*—One of the most vivid recollections of my childhood is of seeing the cook make tinder in the evening by burning old linen rags, and in the morning, with flint and steel, obtaining the spark which, by careful blowing, spread sufficiently to ignite the thin brimstone match from which a candle was lit and fire secured for the day. The process was, however, sometimes a tedious one, and if the tinder had accidentally got damp, or if the flint were worn out, after repeated failures a light had to be obtained from a neighbor. At that time there were few savages in any part of the world but could obtain fire as easily as the most civilized of mankind. . . . About 1834, phosphorus began to be used with other materials to cause more easy ignition, and by 1840 these matches became so cheap as to come into general use in place of the old flint and steel. . . . Whereas down to the end of the last century our modes of producing and utilizing light were almost exactly the same as had been in use for the preceding two or three thousand years, in the present century we have made no less than three new departures, all of which are far superior to the methods of our forefathers. These are: (1) the improvement in lamps by the use of the principle of the Argand burner and chimney; (2) lighting by coal-gas; and (3) the various modes of electric lighting.—WALLACE *The Wonderful Century,* ch. 4, pp. 26-30. (D. M. & Co., 1899.)

1236. FIRE, ITS SERVICE TO SCIENCE—*Man's Friend and Servant—A Chief Factor of Civilization—Gives Power over Nature.*—Looking back through the long dark vista of human history, the one step in material progress that seems to be really comparable in importance with several of the steps we have just made, was, when fire was first utilized, and became the servant and the friend, instead of being the master and the enemy, of man. From that far distant epoch even down to our day, fire, in various forms and in ever-widening spheres of action, has not only ministered to the necessities and the enjoyments of man, but has been the greatest, the essential factor, in that continuous increase of his power over Nature which has undoubtedly been a chief means of the development of his intellect and a necessary condition of what we term civilization. Without fire there would have been neither a bronze nor an iron age, and without these there could have been no effective tools or weapons, with all the long succession of mechanical discoveries and refinements that depended upon them. Without fire there could be no rudiment even of chemistry, and all that has arisen out of it. Without fire much of the earth's surface would be uninhabitable by man, and much of what is now wholesome food would be useless to him. Without fire he must always have remained ignorant of the larger part of the world of matter and of its mysterious forces. He might have lived in the warmer parts of the earth in a savage or even in a partially civilized condition, but he could never have risen to the full dignity of intellectual man, the interpreter and master of the forces of Nature.—WALLACE *The Wonderful Century,* ch. 1, p. 2. (D. M. & Co., 1899.)

1237. FIRE KINDLED BY PRIMITIVE MAN—*Australian Devices.*—The Australians obtain fire by rubbing together two pieces of wood. The process, however, being one of considerable labor, particularly in damp weather, great care is taken to prevent the fire, when once lighted, from becoming extinguished. For this reason they often carry with them a cone of *Banksia,* which burns slowly.—AVEBURY *Prehistoric Times,* ch. 13, p. 425. (A., 1900.)

1238. ——— ——— *Origin of Flint and Steel—The Fire-drill.*—The fire-drill is a means of converting mechanical force into heat till the burning-point of wood is reached. But all that is really wanted is a glowing hot particle or spark, and this can be far more easily got in other ways. Breaking a nodule of iron pyrites picked up on the seashore, and with a bit of flint striking sparks from it on tinder, is a way of firemaking quite superior to the use of the wooden drill. It was known to some modern savages, even the miserable natives of Terra del Fuego: to the prehistoric men of Europe, as appears from the bits of pyrites found in their caves; and of course to the old civilized world, as witness the Greek name of the mineral, *purites,* or "fiery." Substitute for this a piece of iron, and we have the flint and steel, the ordinary apparatus of nations from their entry into the iron age till modern times. Yet even this has now been so discarded that the old-fashioned kitchen tinder-box with its flint and U-shaped steel, and damper for pre-

paring the tinder from scraps of burnt linen to light the brimstone-match with, has become a curiosity worth securing when found by chance in some farmhouse.—TYLOR *Anthropology*, ch. 11, p. 262. (A., 1899.)

1239. FIRE, KINDLING OF, IN BRAZILIAN FOREST—*Primitive Methods Still in Use—Simple Comfort of Life in Wilderness.*—We landed and prepared for breakfast. It was a pretty spot—a clean, white, sandy beach beneath the shade of wide-spreading trees. Joaquim made a fire. He first scraped fine shavings from the midrib of a bacaba-palm leaf; these he piled into a little heap in a dry place, and then struck a light in his bamboo tinder-box with a piece of an old file and a flint, the tinder being a felt-like, soft substance manufactured by an ant *(Polyrhachis bispinosus)*. By gentle blowing the shavings ignited, dry sticks were piled on them, and a good fire soon resulted. He then singed and prepared the cutia, finishing by running a spit through the body, and fixing one end in the ground in a slanting position over the fire. We had brought with us a bag of farinha and a cup containing a lemon, a dozen or two of fiery red peppers, and a few spoonfuls of salt. We breakfasted heartily when our cutia was roasted, and washed the meal down with a calabash-full of the pure water of the river.—BATES *Naturalist on the River Amazon*, ch. 5, p. 663. (Hum., 1880.)

1240. FIRE LIFTS PALL OF NIGHT—*Makes a Way through Darkness.*—Until the savage could command fire, the clouded evening sky left him as if sightless for toil, for sport, for escape from ravening beasts and sudden tempests. If his feet found a beaten path, it was easy to stray from it in darkness, perchance to pay the penalty with his life. His lowly hearth, heaped with crackling boughs, cheered even more with its light than with its warmth. It drew to its rays the industries of flint and needle: its fitful beam created man's first home.—ILES *Flame, Electricity, and the Camera*, ch. 3, p. 25. (D. & McC., 1900.)

1241. FIRE, RIVERS OF—*Modern Street Quarried through Lava—Man's Inattention to Warnings of Nature.*—Burning torrents have often taken their course through the streets of Torre del Greco, and consumed or enclosed a large portion of the town in solid rock. It seems probable that the destruction of three thousand of its inhabitants in 1631, which some accounts attribute to boiling water, was principally due to one of those alluvial floods which we before mentioned: but, in 1737, the lava itself flowed through the eastern side of the town, and afterwards reached the sea; and, in 1794, another current, rolling over the western side, filled the streets and houses, and killed more than four hundred persons. The main street is now quarried through this lava, which supplied building-stones for new houses erected where others had been annihilated. The church was half buried in a rocky mass, but the upper portion served as the foundation of a new edifice.

The number of the population at present is estimated at fifteen thousand; and a satisfactory answer may readily be returned to those who inquire how the inhabitants can be so "inattentive to the voice of time and the warnings of Nature," as to rebuild their dwellings on a spot so often devastated. No neighboring site unoccupied by a town, or which would not be equally insecure, combines the same advantages of proximity to the capital, to the sea, and to the rich lands on the flanks of Vesuvius. If the present population were exiled, they would immediately be replaced by another, for the same reason that the Maremma of Tuscany and the Campagna di Roma will never be depopulated, altho the malaria fever commits more havoc in a few years than the Vesuvian lavas in as many centuries. The district around Naples supplies one amongst innumerable examples, that those regions where the surface is most frequently renewed, and where the renovation is accompanied, at different intervals of time, by partial destruction of animal and vegetable life, may nevertheless be amongst the most habitable and delightful on our globe.—LYELL *Principles of Geology*, bk. ii, ch. 24, p. 394. (A., 1854.)

1242. FIRE, SACRED, KINDLING OF BY BRAHMANS — *Superstition Consecrates Ancient Usage.*—[In India] tho people have for ages kindled fire for practical use with the flint and steel, yet the Brahmans, to make the sacred fire for the daily sacrifice, still use the barbaric art of violently boring a pointed stick into another piece of wood till a spark comes. Asked why they thus waste their labor when they know better, they answer that they do it to get pure and holy fire. But to us it is plain that they are really keeping up by unchanging custom a remnant of the ruder life once led by their remote ancestors.—TYLOR *Anthropology*, ch. 1, p. 16. (A., 1899.)

1243. FIRE STARTED WITH ICE—*A Paradox of Science.*—And now I will substitute for our glass lens one of a more novel character. In a smooth iron mold a lens of pellucid ice has been formed. Placing it in the position occupied a moment ago by the glass lens, I can see the beam brought to a sharp focus. At the focus I place a bit of black paper, with a little gun-cotton folded up within it. The paper immediately ignites and the cotton explodes. Strange, is it not, that the beam should possess such heating power after having passed through so cold a substance? In his arctic expeditions Dr. Scoresby succeeded in exploding gunpowder by the sun's rays converged by large lenses of ice; here we have succeeded in producing the effect

with a small lens, and with a terrestrial source of heat.—TYNDALL *Lectures on Light*, lect. 5, p. 170. (A., 1898.)

1244. FIRE, THE BEAUTY, MAJESTY, AND UTILITY OF—*A Destroying Power Tamed To Minister to Human Needs.*—Who is not struck with the splendor of a brilliantly lighted hall or theater? Indeed, the beauty and luster imparted to large rooms by judicious lighting have no small share in the production of the vivacity felt by the audience generally. Turning to combustion on a large scale, with flames raging in uncontrollable fury, and material undergoing rapid destruction, there is probably no phenomenon in Nature, except, perhaps, the electric discharge, that impresses us with a stronger feeling of awe. A conflagration, from a bonfire to a building in flames, from a chimney on fire to a blast-furnace belching forth its fiery tongues high into the air, is a fit emblem of ungovernable fury and relentless destruction. But it is more to our present purpose to regard flame as an instrument for good rather than evil. Most of the comforts and luxuries and even necessities of modern civilized life are due directly or indirectly to its agency; indeed, it would be difficult to name an art or manufacture which does not owe to flame its very birth. At home and abroad, in the house, the street, and the mart, we are surrounded by a multitude of substances which have been produced by the application of heat in one form or another.—LOWE *Nature-Studies*, p. 1. (Hum., 1888.)

1245. FIRMNESS OF THE "SOLID EARTH"—*Its Rigidity as Great as that of Steel.*—[Since the attraction of sun and moon acts on land as really as on water, it was suggested in 1868] that this criterion might, by the aid of a prolonged series of exact tidal observations, be practically applied to test the interior condition of our planet. In 1882, accordingly, suitable data extending over thirty-three years having at length become available, Professor G. H. Darwin performed the laborious task of their analysis, with the general result that the "effective rigidity" of the earth's mass must be at least as great as that of steel.—CLERKE *History of Astronomy*, pt. ii, ch. 7, p. 317. (Bl., 1893.)

1246. FISH CANNOT LIVE IN GREAT SALT LAKE—*Lower Organisms Flourish—Aquatic Birds Find Food.*—The brine of the [Great Salt] lake is so concentrated that fish cannot live in it, but it furnishes a congenial home for small crustaceans known as brine shrimps *(Artemia)* and for the larvæ of dipterous insects. These are abundant at certain seasons, but not in such vast numbers as in some of the more alkaline lakes on the west side of the Great Basin. It has been stated that the vast numbers of crustaceans and of larvæ in these waters are due to the fact that there are no fishes or other animals in the lakes that could prey upon them; aquatic birds, however, feed upon them in great numbers, but still they swarm in countless myriads. Their food seems to be minute algæ, of which several species have been described.—RUSSELL *Lakes of North America*, ch. 4, p. 83. (G. & Co., 1895.)

1247. FISH EJECTED FROM VOLCANOES—*Life in Subterranean Lakes—Deluges of Mud in the Andes.*—Deluges are often caused in the Andes by the liquefaction of great masses of snow, and sometimes by the rending open, during earthquakes, of subterranean cavities filled with water. In these inundations fine volcanic sand, loose stones, and other materials which the water meets with in its descent are swept away, and a vast quantity of mud, called "moya," is thus formed and carried down into the lower regions. Mud derived from this source descended, in 1797, from the sides of Tungurahua in Quito, and filled valleys a thousand feet wide to the depth of six hundred feet, damming up rivers and causing lakes. In these currents and lakes of moya, thousands of small fish are sometimes enveloped, which, according to Humboldt, have lived and multiplied in subterranean cavities.—LYELL *Principles of Geology*, bk. ii, ch. 22, p. 348. (A., 1854.)

1248. ——— ——— *Pestilence Resulting from Decay of Volcanic Fishes.*—Subterranean lakes, communicating by various channels with the mountain streams, are frequently formed in deep and vast cavities, either on the declivity or at the base of volcanoes. When the whole mass of the volcano is powerfully shaken by those earthquakes which precede all eruptions of fire in the Andes, the subterranean vaults open and pour forth streams of water, fishes, and tufaceous mud. This singular phenomenon brings to mind the *Pimelodes Cyclopum*, or the Silures of the Cyclops, which the inhabitants of the plateau of Quito call Preñadilla, and of which I gave a circumstantial account soon after my return to Europe. When, on the night between the 19th and 20th of June, 1698, the summit of Mount Carguairazo, situated to the north of Chimborazo, and having an elevation of more than 19,000 feet, fell in, all the country for nearly 32 square miles was covered with mud and fishes. A similar eruption of fish from the volcano of Imbaburu was supposed to have caused the putrid fever which, seven years before this period, raged in the town of Ibarra.—HUMBOLDT *Views of Nature*, p. 367. (Bell, 1896.)

1249. FISH ITS OWN LIGHT-BEARER—In *Opostomias micripnus*, a dark black fish living at a depth of over 2,000 fathoms, there are two rows of ocellar organs running down the sides of the body from the head to the tail. In the living animal they are said

to shine with a reddish luster.—HICKSON *Fauna of the Deep Sea*, ch. 4, p. 78. (A., 1894.)

1250. FISH KILLING HORSES—*The Electric Eel—Electricity in the Waters.*—The crocodile and the jaguar are not, however, the only enemies that threaten the South-American horse; for even among the fishes it has a dangerous foe. The marshy waters of Bera and Rastro are filled with innumerable electric eels, who can at pleasure discharge from every part of their slimy, yellow-speckled bodies a deadening shock. This species of *Gymnotus* is about five or six feet in length. It is powerful enough to kill the largest animals when it discharges its nervous organs at one shock in a favorable direction. It was once found necessary to change the line of road from Uritucu across the steppe, owing to the number of horses which, in fording a certain rivulet, annually fell a sacrifice to these gymnoti, which had accumulated there in great numbers. All other species of fish shun the vicinity of these formidable creatures. Even the angler, when fishing from the high bank, is in dread lest an electric shock should be conveyed to him along the moistened line. Thus, in these regions, the electric fire breaks forth from the lowest depths of the waters.—HUMBOLDT *Views of Nature*, p. 17. (Bell, 1896.)

1251. FISHES ENTICED WITHIN NET—With a humoristic sideglance at human relations, Aelian describes how a delicate Mediterranean fish, called *Scarus*, was caught. A female fish was fastened to a line weighted with lead and then dragged to the spot over which the nets had been spread. Then after the males, in their fatal amorousness, had followed close enough, the fisher would drop his lead into the net, and the female together with the whole of her dazzled following would be dragged within. —HOFFMAN *Das Blei bei den Volkern des Alterthums*. (Translated for *Scientific Side-Lights*.)

1252. FISSURES, VAST AND DEEP, FORMED BY EARTHQUAKES—*Fragility of the "Solid Earth."*—The magnitude of some of the fissures formed during [the Calabrian] earthquake affords startling indications of the tremendous violence of the earth's internal throes. Grimaldi observed in the territory of San Fili a newly formed ravine half a mile long and twenty-five feet deep, and another of similar dimensions in Rosarno. In the district of Plaisano three enormous fissures were formed: one a quarter of a mile long, about thirty feet in width, and 225 feet deep; the second, three-quarters of a mile long, 150 feet broad, and 100 feet deep; and the third, nearly a mile long, 105 feet broad, and thirty feet deep. If any evidence were required as to the true nature of the disturbance, it would be found in the remarkable motions of masses slightly attached to the surface soil. Paving-stones were flung into the air, masses of loose soil flung in showers over the surrounding objects.—PROCTOR *Notes on Earthquakes*, p. 4. (Hum., 1887.)

1253. FIXITY IN CHANGE—*The Cloud about a Mountain-top.*—Mr. Daniell has observed, in his meteorological essays, that a cloud sometimes appears fixed on a mountain summit, while the wind continues to blow over it. The same phenomenon here presented a slightly different appearance. In this case the cloud was clearly seen to curl over, and rapidly pass by the summit, and yet was neither diminished nor increased in size. The sun was setting, and a gentle southerly breeze, striking against the southern side of the rock, mingled its current with the colder air above; and the vapor was thus condensed: but as the light wreaths of cloud passed over the ridge, and came within the influence of the warmer atmosphere of the northern sloping bank, they were immediately redissolved. — DARWIN *Naturalist's Voyage around the World*, ch. 2, p. 28. (A., 1898.)

1254. FIXITY OF SOLIDS DELUSIVE—*The Flowing of Metals—Lead and Gold Interpenetrate Each Other.*—One of the most characteristic properties of gases and liquids is that of readily mixing together when placed in contact. But it has recently been shown that solids also mix, tho very much more slowly. If a cube of lead is placed upon one of gold, the surfaces of contact being very smooth and true, and be left without any pressure but their own weight, and at ordinary temperatures, for about a month, a minute quantity of gold will be found to have permeated through the lead, and can be detected in any part of it. Metals may thus be said to flow into each other.—WALLACE *The Wonderful Century*, ch. 7, p. 56. (D. M. & Co., 1899.)

1255. FIXITY OF THE EARTH ONCE ASSUMED—*Cosmogony of Homer—Thought of the Earth as Detached a Surprise—All Subterfuges of Support Fail—"He Stretcheth Out the North over the Empty Place, and Hangeth the Earth upon Nothing" (Job xxvi, 7).*—At the epoch of Homer (about 900 years before our era) it was believed that the earth, surrounded by the river Okeanos, filled the lower half of the celestial sphere, while the upper half extended above, and that Helios (the sun) extinguished his fires each evening and relit them in the morning after bathing in the deep waters of the ocean. . . . Many Greek astronomers still believed, 2,000 years ago, that the stars were fires fed by exhalations from the earth. They were soon forced to remark that the sun, the moon, the planets, and the stars rise and set, and that during the hours which elapse between their setting and their rising it was absolutely necessary that the stars should pass under the earth. Under the earth! What a revolution is in these three words! Up to that time they

had supposed that the world extended to infinity below our feet, solidly founded forever, and, without comprehending this infinite extension of matter, they remained in ignorance and believed in the firm solidity of the earth. But when the curves described by the stars above our heads were continued, after they set below the horizon, to start again when they rose, it was necessary to imagine the earth pierced right through with tunnels large enough to permit the passage of the celestial torches. . . . But the idea of supporting the earth on mountains or otherwise only evades the difficulty, for these mountains, elephants, or columns would, of course, require to rest on some lower foundation. As, moreover, the sky seems to turn round in one piece, the subterfuges invented in order to preserve for the earth something of its [supposed] original stability at last disappeared by the force of circumstances, and they were obliged to admit that *the earth is isolated in all its parts*.—FLAMMARION *Popular Astronomy*, ch. 1, p. 5. (A.)

1256. FLAME THE FRANKENSTEIN OF ALCHEMISTS—*The Real Wonder-worker—Man Must Work with Nature's Laws.*—Flame was the mighty Frankenstein to whom the old alchemists looked for aid in their visionary schemes of transmutation: but since the time of those assiduous but misguided philosophers, flame has worked greater wonders than ever entered into their wildest fancies. The diligent experimenter may be assured that much still remains undisclosed, and that by means of the Bunsen burner, blowpipe, and blast-gas furnace, discoveries have yet to be made which will, at the same time, startle and benefit the world. Our experiments, however, must not be simply tentative; they must be begun, continued, and ended in accordance with physical laws, which will never change, whatever may be the ultimate revolution in scientific theories. By heat the elements can be separated, and by the same agency they can be combined; the more perfect, therefore, our knowledge of chemical action and reaction, the more likely are our researches to terminate in satisfactory results.—LOWE *Nature-Studies*, p. 10 (Hum., 1888.)

1257. FLAVORS AND ODORS CHEMICALLY PRODUCED — *Fruit-sirups — Old Wines and Whiskies Successfully Imitated.*—The delicious fruit-sirups expressly prepared from the fruits themselves, which we find advertised at the alleged soda-fountains, are, in most cases, the products of the chemical laboratory. The achievements of synthetic conquest have been pushed even to a greater extent, and we find it possible to produce mixtures of ethers and essential oils, the pure fabrications of the chemist, which resemble in every respect the natural products arising from the aging of whisky and wine. With a half-dozen bottles of essences which you may purchase in Cincinnati, a barrel of alcohol which you can get from one of Uncle Sam's bonded warehouses, and a pound of burnt sugar which you can make yourself, you can in a few hours make two barrels and a half of ten-year-old Bourbon. In this day, when great universities spring up in a night, with all the facilities and appointments which centuries were supposed to produce, it is not so strange to find the chemist also annihilating time and obliterating space.—WILEY *Relations of Chemistry to Industrial Progress (Address at Purdue University, Lafayette, Ind., 1896*, p. 30).

1258. FLIGHT OF BIRDS A NATURAL GIFT—*Young Swallows Fly Perfectly with No Instruction.*—Mr. Spalding's observations on this point are conclusive as to birds (*Nature*, xii, 507):

"Birds," he says, "do not learn to fly. Two years ago I shut up five unfledged swallows in a small box, not much larger than the nest from which they were taken. The little box, which had a wire front, was hung on the wall near the nest, and the young swallows were fed by their parents through the wires. In this confinement, where they could not even extend their wings, they were kept until after they were fully fledged. . . . On going to set the prisoners free, one was found dead. . . . The remaining four were allowed to escape one at a time. Two of these were perceptibly wavering and unsteady in their flight. One of them, after a flight of some ninety yards, disappeared among some trees." No. 3 and No. 4 "never flew against anything, nor was there, in their avoiding objects, any appreciable difference between them and the old birds. No. 3 swept round the Wellingtonia, and No. 4 rose over the hedge, just as we see the old swallows doing every hour of the day. I have this summer verified these observations. Of two swallows I had similarly confined, one, on being set free, flew a yard or two close to the ground, rose in the direction of a beech-tree, which it gracefully avoided; it was seen for a considerable time sweeping round the beeches and performing magnificent evolutions in the air high above them. The other, which was observed to beat the air with its wings more than usual, was soon lost to sight behind some trees. Titmice, tomtits, and wrens I have made the subjects of similar observations, and with similar results."—JAMES *Psychology*, vol. ii, ch. 24, p. 406. (H. H. & Co., 1899.)

1259. FLOOD AT TIVOLI—*Church and Dwellings Destroyed—Ancient Pagan Temple Spared.*—The younger Pliny, it will be remembered, describes a flood on the Anio, which destroyed woods, rocks, and houses, with the most sumptuous villas and works of art. For four of five centuries consecutively, this "headlong stream," as Horace truly called it, has often remained within

its bounds, and then, after so long an interval of rest, has at different periods inundated its banks again, and widened its channel. The last of these catastrophes happened 15th Nov., 1826, after [continuous] heavy rains. . . . The waters appear also to have been impeded by an artificial dike, by which they were separated into two parts, a short distance above Tivoli. They broke through this dike, and leaving the left trench dry, precipitated themselves, with their whole weight, on the right side. Here they undermined, in the course of a few hours, a high cliff, and widened the river's channel about fifteen paces. On this height stood the church of St. Lucia, and about thirty-six houses of the town of Tivoli, which were all carried away, presenting, as they sank into the roaring flood, a terrific scene of destruction to the spectators on the opposite bank. As the foundations were gradually removed, each building, some of them edifices of considerable height, was first traversed with numerous rents, which soon widened into large fissures, until at length the roofs fell in with a crash, and then the walls sunk into the river, and were hurled down the cataract below.

The destroying agency of the flood came within two hundred yards of the precipice on which the beautiful temple of Vesta stands; but fortunately this precious relic of antiquity was spared, while the wreck of modern structures was hurled down the abyss.—LYELL *Principles of Geology*, bk. ii, ch. 14, p. 212. (A., 1854.)

1260. FLOOD IN THE WHITE MOUNTAINS—*Mountain Stream Becomes a Torrent—Death Found in Seeking Refuge.*—Two dry seasons in the White Mountains, in New Hampshire (United States), were followed by heavy rains on the 28th of August, 1826, when from the steep and lofty declivities which rise abruptly on both sides of the River Saco innumerable rocks and stones, many of sufficient size to fill a common apartment, were detached, and in their descent swept down before them, in one promiscuous and frightful ruin, forests, shrubs, and the earth which sustained them. Altho there are numerous indications on the steep sides of these hills of former slides of the same kind, yet no tradition had been handed down of any similar catastrophe within the memory of man, and the growth of the forest on the very spots now devastated clearly showed that for a long interval nothing similar had occurred. One of these moving masses was afterwards found to have slid three miles, with an average breadth of a quarter of a mile. The natural excavations commenced generally in a trench a few yards in depth and a few rods in width, and descended the mountains, widening and deepening till they became vast chasms. At the base of these hollow ravines was seen a confused mass of ruins, consisting of transported earth, gravel, rocks, and trees. Forests of spruce-fir and hemlock, a kind of fir somewhat resembling our yew in foliage, were prostrated with as much ease as if they had been fields of grain; for, where they disputed the ground, the torrent of mud and rock accumulated behind till it gathered sufficient force to burst the temporary barrier.

The valleys of the Ammonoosuc and Saco presented, for many miles, an uninterrupted scene of desolation, all the bridges being carried away, as well as those over their tributary streams. In some places the road was excavated to the depth of from fifteen to twenty feet; in others it was covered with earth, rocks, and trees to as great a height. The water flowed for many weeks after the flood, as densely charged with earth as it could be without being changed into mud, and marks were seen in various localities of its having risen on either side of the valley to more than twenty-five feet above its ordinary level. Many sheep and cattle were swept away, and the Willey family, nine in number, who in alarm had deserted their house, were destroyed on the banks of the Saco; seven of their mangled bodies were afterwards found near the river, buried beneath driftwood and mountain ruins.—LYELL *Principles of Geology*, bk. ii, ch. 14, p. 209. (A., 1854.)

1261. FOOD DEEPLY AFFECTS ORGANISM—*Diet Changes Color of Birds.*—In some instances it is known that a bird's color is affected by the nature of its food. It is a common practise among bird fanciers to alter the color of canaries from yellow to orange-red by feeding them on red pepper. This food, however, is said to have no effect upon adult birds, but must be fed to nestlings. Sauermann's experiments, as quoted by Beddard, show that the red color is not caused by the capsicin or red pigment in the pepper, but by a fatty substance termed triolein. Fed to white fowls, their breasts became red, while the rest of the plumage remained unchanged. It is also stated that dealers alter the color of green parrots to yellow by feeding them on the fat of certain fishes.—CHAPMAN *Bird-Life*, ch. 3, p. 39. (A., 1900.)

1262. FOOD, DEFINITION AND PURPOSE OF—*Heat and Energy Partial Results—The Building-up of the Body—Construction of Protoplasm the Great Requisite.*—We must decide what we mean by a food, and upon what depend its nourishing qualities. The answer of the current doctrines is that the purpose of a food is to supply, by its oxidation, energy to the organism for its activity and heat. This definition is, to say the least, one-sided, because it completely ignores another very important function of food; namely, its purpose of serving for the construction of the organism. We know that the growing organism can grow only by means of the substances furnished by food: accordingly, that every organism, including the full-grown, can replace what is lost

through physiological functions or disease only by food. For this function of food, which, unfortunately, is often neglected in the theoretical discussions, it is not the caloric value, the latent energy, contained in a substance, but its constructive value, *i. e.*, its power to take part in the building-up of the body, that is of importance. The same holds good for all the substances serving as food for green plants, which consist of completely oxidized compounds, and which hence possess no fuel-value. Yet plants live and breathe as well as animals; their protoplasm shows irritability as well as that of animals, and also develops heat and other vital energies by its activity. In this case we see the customary theory, that food is the bearer of energy, does not hold good, because here the nourishment does not contain energy and can only serve to build up the vegetable organism.

Moreover, certain inorganic substances are indispensable for the animal organism, the growing as well as the full-grown one, and these are in part the same, potassium, calcium, magnesium, and iron compounds, which the plants require for their growth. These facts are inexplicable on the basis of the theory that the purpose of food is to furnish the body with energy, but they are at once clear when we assume that these combinations are used by the animal as well as the vegetable organism for the formation and replacing of protoplasm.

The same is true with regard to the organic elements of animal food. As long as we think they are simply consumed in the fluids of the body for the purpose, as we have heard, of furnishing material for heat and energy, the doctrine of nutrition will labor with a list of enigmas and contradictions which submit to solution in the simplest way as soon as we recognize the other possibility that they are also employed for the construction and reconstruction of the living and working protoplasm. —KASSOWITZ *Is Alcohol a Food or a Poison?* A paper, p. 9. (Translation by Mrs. J. H. W. STUCKENBERG.)

1263. FOOD, FALLACIES REGARDING —*Analysis of Substances in Raw State—Cookery Ignored—Assimilation Unheeded.*—A great many fallacies are continually perpetrated not only by ignorant people, but even by eminent chemists and physiologists. In many chemical and physiological works may be found elaborately minute tables of the chemical composition of certain articles of food, and with these the assumption (either directly stated or implied as a matter of course) that such tables represent the practical nutritive value of the food. The illusory character of such assumption is easily understood. In the first place the analysis is usually that of the article of food in its raw state, and thus all the chemical changes involved in the process of cookery are ignored.

Secondly, the difficulty or facility of assimilation is too often unheeded. This depends both upon the original condition of the food and the changes which the cookery has produced—changes which may double its nutritive value without effecting more than a small percentage of alteration in its chemical composition as revealed by laboratory analysis.—WILLIAMS *Chemistry of Cookery*, ch. 1, p. 5. (A., 1900.)

1264. FOOD, NATURAL CONSTITUENTS NEEDED IN—*Gelatin Will Not Support Life—The "Bone-soup" Experiments of the French Academy.*—About fifty or sixty years ago the French Academy of Sciences appointed a bone-soup commission, consisting of some of the most eminent savants of the period. They worked for above ten years upon the problem submitted to them, that of determining whether or not the soup made by boiling bones until only their mineral matter remained solid, is, or is not, a nutritious food for the inmates of hospitals, etc. In the voluminous report which they ultimately submitted to the Academy they decided in the negative. Baron Liebig became the popular exponent of their conclusions, and vigorously denounced gelatin as not merely a worthless article of food, but as loading the system with material that demands wasteful effort for its removal. The academicians fed dogs on gelatin alone [and] found that they speedily lost flesh, and ultimately died of starvation. A multitude of similar experiments showed that gelatin alone will not support animal life, and hence the conclusion that pure gelatin is worthless as an article of food, and that ordinary soups containing gelatin owed their nutritive value to their other constituents.—WILLIAMS *Chemistry of Cookery*, ch. 4, p. 36. (A., 1900.)

1265. FOOD, NECESSITY OF, A CAUSE OF MIGRATION—*Prevision of Unknown Peril.*—Food, and the necessity for obtaining it, have been adduced as the principal causes of migration from north to south or from east to west, and to a certain extent this is true. The birds which breed in the arctic regions, and along the shores of Russia, Siberia, and the "barren lands" of North America, the snow buntings, the geese, the ducks, the turnstones, and a host of others, must necessarily seek milder latitudes if they are to live when the snow covers their feeding-grounds, while it is equally evident that insect-eating birds, like the swallow, cannot remain long in regions from which insect life disappears for several months in the year.—BROWN *Nature-Studies*, p. 16. (Hum., 1888.)

1266. FOOD OF DEEP-SEA ANIMALS —*Must Descend from Surface.*—The absence of vegetable life is an important point in the consideration of the abysmal fauna, for it is in consequence necessary to bear in mind that the food of deep-sea animals must be derived from the surface. It is possible that deep-sea fish, in some cases, feed upon

one another and upon deep-sea crustacea, that deep-sea crustacea feed upon deep-sea worms, that deep-sea echinoderms feed upon deep-sea foraminifera, and so on through all the different combinations; but the fauna would soon become exhausted if it had no other source of food-supply. This other source of food-supply is derived from the bodies of pelagic organisms that fall from the upper waters of the ocean, and is composed of protozoa, floating tunicates, crustacea, fish, and other animals, together with diatoms and fragments of seaweed.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 43. (A., 1894.)

1267. FOOD OF ENTOMBED RHINOCEROS—*Science Brings Past to Present.*—In 1772, Pallas obtained from Wiljuiskoi, in lat. 64°, from the banks of the Wiljui, a tributary of the Lena, the carcass of a rhinoceros *(R. tichorhinus)*, taken from the sand in which it must have remained congealed for ages, the soil of that region being always frozen to within a slight depth of the surface. This carcass was compared to a natural mummy, and emitted an odor like putrid flesh, part of the skin being still covered with black and gray hairs. So great, indeed, was the quantity of hair on the foot and head conveyed to St. Petersburg, that Pallas asked whether the rhinoceros of the Lena might not have been an inhabitant of the temperate regions of middle Asia, its clothing being so much warmer than that of the African rhinoceros.

Professor Brandt, of St. Petersburg, in a letter to Baron Alexander von Humboldt, dated 1846, adds the following particulars respecting this wonderful fossil relic: "I have been so fortunate as to extract from cavities in the molar teeth of the Wiljui rhinoceros a small quantity of its half-chewed food, among which fragments of pine-leaves, one-half of the seed of a polygonaceous plant, and very minute portions of wood with porous cells (or small fragments of coniferous wood), were still recognizable.—LYELL *Principles of Geology*, bk. i, ch. 6, p. 80. (A., 1854.)

1268. FOOD OF PLANT PRESERVED TILL CONSUMED—*Antiseptic Power of Secretion of Sundew.*—The secretion seems to possess, like the gastric juice of the higher animals, some antiseptic power. During very warm weather I placed close together two equal-sized bits of raw meat, one on a leaf of the *Drosera* [sundew], and the other surrounded by wet moss. They were thus left for 48 hours, and then examined. The bit on the moss swarmed with infusoria, and was so much decayed that the transverse *striæ* on the muscular fibers could no longer be clearly distinguished; whilst the bit on the leaf, which was bathed by the secretion, was free from infusoria, and its *striæ* were perfectly distinct in the central and undissolved portion. In like manner small cubes of albumin and cheese placed on wet moss became threaded with filaments of mold, and had their surfaces slightly discolored and disintegrated; whilst those on the leaves of *Drosera* remained clean, the albumin being changed into transparent fluid.—DARWIN *Insectivorous Plants*, ch. 1, p. 12. (A., 1898.)

1269. FOOD OF SAVAGES—*Snakes, Lizards, Grubs, and Ants Eaten by Rude Tribes—Dearth in Lack of Agriculture.*—His [man's] first need is to get his daily food. In tropical forests, savages may easily live on what Nature provides, like the Andaman Islanders, who gather fruits and honey, hunt wild pigs in the jungle, and take turtle and fish on the coast. Many forest tribes of Brazil, tho they cultivate a little, depend mostly on wild food. Of such the rude man has no lack, for there is game in plenty and the rivers swarm with fish, while the woods yield him a supply of roots and bulbs, calabashes, palm-nuts, beans, and many other fruits; he collects wild honey, birds' eggs, grubs out of rotten wood, nor does he despise insects, even ants. In less fertile lands savage life goes on well while game and fish abound, but when these fail it becomes an unceasing quest for food, as where the Australians roam over their deserts on the lookout for every eatable root or insect, or the low Rocky Mountain tribes gather pine-nuts and berries, catch snakes, and drag lizards out of their holes with a hooked stick.—TYLOR *Anthropology*, ch. 9, p. 206. (A., 1899.)

1270. FOOD OF THE WORLD FOUND IN FRUITS AND SEEDS—*Vegetable Altruism—The Plant Lives for Others.*—All animals, in the long run, depend for food upon fruits and seeds, or upon lesser creatures which have utilized fruits and seeds. Three-fourths of the population of the world at the present moment subsist upon rice. What is rice? It is a seed; a product of reproduction. Of the other fourth, three-fourths live upon grains—barley, wheat, oats, millet. What are these grains? Seeds—stores of starch or albumin which, in the perfect forethought of reproduction, plants bequeath to their offspring. The foods of the world, especially the children's foods, are the foods of the children of plants, the foods which unselfish activities store round the cradles of the helpless, so that when the sun wakens them to their new world they may not want. Every plant in the world lives for others. It sets aside something, something costly, cared for, the highest expression of its nature.—DRUMMOND *Ascent of Man*, ch. 7, p. 228. (J. P., 1900.)

1271. FOOD, ONE ARTICLE OF, UNIVERSAL—*The Value of Bread.*—If it is a fact that the kind and variety of nourishment exercise the greatest influence upon the state of health, the capacity for work and endurance, it must be of very special importance to become ac-

quainted with the dietetic value of bread. Among all nations throughout the temperate zone it is the principal means of nourishment for every one, rich as well as poor, high as well as lowly, young and old. It forms the basis of the entire nourishment; it is never wanting on the table, morning, midday, or evening; it accompanies the laborer to his work, the child to school, the traveler on his journey, and, altho eaten every day, always remains popular, is always desired.—UFFELMANN *Das Brod und dessen dietetischer Werth.* (Translated for *Scientific Side-Lights.*)

1272. FOOD, PERMANENT SUPPLY OF —*Granaries the Invention of Woman.*—There is abundant proof among the three typical divisions of humanity still living in savagery—the American Indian, the negroid races, and the Malayo-Polynesians—that women were the builders and owners of the first caches, granaries, and storehouses of provisions.—MASON *Woman's Share in Primitive Culture,* ch. 2, p. 18. (A., 1894.)

1273. FOOD RATHER THAN STIMULANT — *Sustaining Properties of Cocoa or Chocolate — A Traveler's Resource.* — Another essential difference between cocoa and tea or coffee is that cocoa is, strictly speaking, a food. We do not merely make an infusion of the cacao-bean, but eat it bodily in the form of a soup. It is highly nutritious, one of the most nutritious foods in common use. When traveling on foot in mountainous and other regions, where there was a risk of spending the night *al fresco* and supperless, I have usually carried a cake of chocolate in my knapsack, as the most portable and unchangeable form of concentrated nutriment, and have found it most valuable. On one occasion I went astray on the Kjolenfjeld, in Norway, and struggled for about twenty-four hours without food or shelter. I had no chocolate then, and sorely repented my improvidence. Many other pedestrians have tried chocolate in like manner, and all I know have commended its great "staying" properties, simply regarded as food. I therefore conclude that Linnæus was not without strong justification in giving it the name of *theobroma* (food for the gods), but to confirm this practically the pure nut, the whole nut, and nothing but the nut (excepting the milk and sugar added by the consumer) should be used. Some miserable counterfeits are offered—farinaceous paste, flavored with cocoa and sugar. The best sample I have been able to procure is the ship cocoa prepared for the navy. This is nothing but the whole nut unsweetened, ground, and crushed to an impalpable paste.—WILLIAMS *Chemistry of Cookery,* ch. 15, p. 263. (A., 1900.)

1274. FOOD, SAVORY, THE MORE NUTRITIOUS—*Bone-soup Problem—Conclusions from Experiments of French Academy—Science Increases Human Sustenance.*—The inferences drawn by M. Edwards [from the experiments of the French Academy on bone soup] are that, to render gelatin soup equal in nutritive and digestible qualities to that prepared from meat alone, it is sufficient to mix one-fourth of meat soup with three-fourths of gelatin soup; and that, in fact, no difference is perceptible between soup thus prepared and that made solely from meat; that in preparing soup in this way, the great advantage remains that while the soup itself is equally nourishing with meat soup, three-fourths of the meat which would be requisite for the latter by the common process of making soup are saved and made useful in another way—as by roasting, etc.; that jellies ought always to be associated with some other principles to render them both nutritive and digestible. A young dog that had ceased growing, and had lost one-fifth of its original weight when fed on bread and gelatin for thirty days, was next supplied with the same food, but to which was added, twice a day, only two tablespoonfuls of soup made from horseflesh. There was an increase of weight on the first day, and "in twenty-three days the dog had gained considerably more than its original weight, and was in the enjoyment of vigorous health and strength." All this difference was due to the savory constituents of the four tablespoonfuls of meat soup, which soup contained the juices of the flesh, to which, as already stated, its flavor is due.—WILLIAMS *Chemistry of Cookery,* ch. 4, p. 38. (A., 1900.)

1275. FOOD, TOXIC SUBSTANCE NOT A—*Alcohol Not Nutritious—An Undesirable Saving.*—It is therefore wholly inappropriate to speak of alcohol as fat-saving, and there is still less sense in regarding a toxic substance as food because the protoplasm it has destroyed is no longer capable of taking part in the vital processes and the oxidations associated with them. Nor is there any reason for speaking of a desirable saving, or, indeed, of a nourishing function of alcohol, if by benumbing the brain-centers it lowers the functional activity of the organs innervated by them, and thus causes a diminution of the oxidation process accompanying their activity.—KASSOWITZ *Is Alcohol a Food or a Poison?* p. 14. (Translation by MRS. J. H. W. STUCKENBERG.)

1276. FOOD, VARIETY OF, A NECESSITY—*Balance of Carbon and Nitrogen—Waste of Tissues Must Be Supplied.*—In order that life may be maintained it is necessary that the body should be supplied with food in proper quality and quantity.

The food taken in by the animal body is used for the purpose of replacing the waste of the tissues. And to arrive at a reasonable estimation of the proper diet in twenty-four hours it is necessary to consider the amount of the excreta daily eliminated from the body. The excreta contain chiefly carbon, hydrogen, oxygen, and nitrogen, but

also, to a less extent, sulfur, phosphorus, chlorin, potassium, sodium, and certain other of the elements. Since this is the case it must be evident that, to balance this waste, foods must be supplied containing all these elements to a certain degree, and some of them, viz., those which take the principal part in forming the excreta, in large amount. . . . The quantity of carbon daily lost from the body amounts to about 281.2 grams or nearly 4,500 grains, and of nitrogen 18.8 grams, or nearly 300 grains: and if a man could be fed by these elements, as such, the problem would be a very simple one; a corresponding weight of charcoal, and, allowing for the oxygen in it, of atmospheric air, would be all that is necessary. But an animal can live only upon these elements when they are arranged in a particular manner with others, in the form of an organic compound, as albumin, starch, and the like; and the relative proportion of carbon to nitrogen in either of these compounds alone is, by no means, the proportion required in the diet of man. Thus, in albumin the proportion of carbon to nitrogen is only as 3.5 to 1. If, therefore, a man took into his body, as food, sufficient albumin to supply him with the needful amount of carbon, he would receive more than four times as much nitrogen as he wanted; and if he took only sufficient to supply him with nitrogen, he would be starved for want of carbon. It is plain, therefore, that he should take with the albuminous part of his food, which contains so large a relative amount of nitrogen in proportion to the carbon he needs, substances in which the nitrogen exists in much smaller quantities relatively to the carbon.

It is therefore evident that the diet must consist of several substances, not of one alone, and we must therefore turn to the available food-stuffs.—BAKER *Handbook of Physiology*, vol. i, ch. 7, p. 212. (W. W., 1885.)

1277. FOODS, ADULTERATION OF—*The Perversion of Science—Injurious or Dangerous Preservatives.*—In the adulteration of foods, unfortunately, the fraud is not always confined to matters harmless to health. Bad as any adulteration of an article of food or drink may be, it is not of the highest class of criminality when the fraudulent practises consist in the addition of harmless substances, but the health of the consumer becomes endangered when adulterations assume a poisonous character or are of a nature which by constant use will produce disturbances in the vital functions. Many bodies which have poisonous qualities are often introduced into foods either for the purpose of preserving them or of adding to the attractiveness of their appearance. Among preservatives which are commonly found, and which may be regarded as injurious, may be mentioned sulfurous and salicylic acids and borax. These bodies, when taken in minute quantities and for short intervals of time, produce no deleterious effects whatever. When, however, they are used for an indefinite period, they tend to derange the digestive organs and impair health. . . . The seemingly natural red color of preserved meats is secured by the use of niter and other similar objectionable agents.—WILEY *Relations of Chemistry to Industrial Progress (Address at Purdue University, Lafayette, Ind., 1896*, p. 42).

1278. FOODS, NUTRITIVE VALUE OF—*Advantage of Scientific Analysis—Benefit to Animals and Man.*—In the matter of foods the chemist has also made investigations in another direction which are of the utmost importance to industrial progress. He has investigated, first, from a purely scientific basis, the problems of nutrition. He has shown that certain characters of foods in the animal economy tend to produce certain results, and as a result of these investigations is able to prepare a ration which in any given case will meet the requirements desired. The pig which is fed for market requires quite a different ratio in the ingredients of its food-principles from the cow that is fed for milk or butter. Three great food-principles are recognized, viz., fats, carbohydrates, and proteids. It is possible, by a judicious combination of these great food-principles, to produce in any given case a ration which will secure the effect desired in the most economical way. By following rigidly the principles which have thus been established by scientific research, it is possible at the present day to prepare a hundred pounds of pork for market at a cost fully one-third less than was required by the haphazard method pursued a quarter of a century ago. . . . Wider fields of utility, however, open up before the possibilities of chemical investigation in the matter of human foods. If pigs deserve to be fed on balanced rations, and steers stand in wait for the mandates of science before they chew their cuds, it is not too much to ask that man himself should receive some consideration.—WILEY *Relations of Chemistry to Industrial Progress (Address at Purdue University, Lafayette, Ind., 1896*, p. 44).

1279. FOODS, THE CHEMISTRY OF—*The Body Heated Like a Stove.*—The food of man and animals consists of two classes of substance differing essentially in composition. The one class (consisting of nitrogenous substances, albumin, etc.) serves in the formation of blood and in building up the various organs of the body; this is called plastic food. The other (consisting of non-nitrogenous substances, the fatty bodies, and the so-called carbohydrates) resembles ordinary fuel and serves in the generation of heat; this is designated by the term respiratory food. Sugar, starch, or gum may be looked upon as modified woody fiber, from which it is known that they are capable of being formed. Fat, from the

quantity of carbon it contains, stands nearest to coal. We heat our bodies precisely as we heat a stove, with fuel that contains the same elements as wood and coal, but differs essentially from the latter substances in being soluble in the juices of the body.—LIEBIG *Ueber die Verwandlung der Kräfte (Sammlung wissenschaftlicher Vorträge, gehalten zu München, 1858*, p. 594). (Translated for *Scientific Side-Lights.)*

1280. FORCE A REFLECTION OF MAN'S CONSCIOUS EFFORT—If we trace all our conceptions on the nature of force to their fountain-head, we shall find that they are formed on our own consciousness of living effort—of that force which has its seat in our own vitality, and especially on that kind of it which can be called forth at the bidding of the will.—ARGYLL *Reign of Law*, ch. 2, p. 72. (Burt.)

1281. FORCE, ATOMIC, EXCEEDS GRAVITATION—*Energy Required to Heat a Pound Would Lift Tons.*—As measured by any ordinary mechanical standard, the magnitude of the forces engaged in this atomic motion and interior work is enormous. A pound of iron, on being heated from 0° C. to 100° C., expands by about $\frac{1}{300}$th of the volume which it possesses at 0°. Its augmentation would certainly escape the most acute eye; still, to give its atoms the motions corresponding to this increase of temperature, and to shift them through the small space indicated, an amount of heat is requisite which would raise a weight of about eight tons one foot high. The force of gravity almost vanishes in comparison with these molecular forces; the pull of the earth upon our pound weight, as a mass, is as nothing compared with the mutual pull of its own atoms.—TYNDALL *Heat a Mode of Motion*, lect. 7, p. 185. (A., 1900.)

1282. FORCE, BRUTE, AT HIGHEST POINT ERE MAN APPEARS—*Human Intelligence Conquers—Giant Mammals Become Extinct.*—The earlier mammalia were giants in comparison with those now living. The mastodon and mammoth as compared with the modern elephant, the megatherium as compared with the sloth or ant-eaters of present times, the hyenas and bears of the European caverns, and the fossil elk of Ireland, by the side of which even the moose of our Northern woods is belittled, are remarkable instances in proof of this. One cannot but be struck with the fact that this first representation of mammalia, the very impersonation of brute force in power, size, and ferocity, immediately preceded the introduction of man, with whose creation intelligence and moral strength became the dominant influences on earth.—AGASSIZ *Geological Sketches*, ser. i, ch. 7, p. 195. (H. M. & Co., 1896.)

1283. FORCE, ELECTRICAL—*Faraday's Discovery—Marvelous Applications within Fifty Years.*—It is only a little over half a century since Faraday made his discovery [of the production of an electrical current by the movement of a conducting body in a magnetic field]. As a result of this observation, so apparently unimportant, we see to-day an entirely new curriculum of study in all of our great schools. The science of electrical engineering is a direct outgrowth of Faraday's observation. We have seen already a complete revolution in the methods of transporting passengers in cities, growing out of this discovery. Rapidly are coming changes in the transmission of energy and in the utilization of the waste forces of Nature. Torrents and cataracts are made to do valuable work for humanity hundreds of miles from their localities. A new system of illumination has sprung up over the whole civilized world, displacing oil and gas. It requires no prophet to foresee the day when the development of electrical energy made possible by Faraday's discovery will be accomplished far more economically than at the present, perhaps even permitting the direct conversion of burning fuel into electrical force. . . . Could there be a more striking illustration of what a discovery in pure science, developed by skilful technologists, can do in the promotion of human industry?—WILEY *Relations of Chemistry to Industrial Progress (Address at Purdue University, Lafayette, Ind., 1896*, p. 21).

1284. FORCE, ENORMOUS, OF CHEMICAL COMBINATION—*Measured in Terms of Falling Body.*—It has been stated that when a body falls to the earth it is warmed by the shock. Here, to use the terminology of Mayer, we have a mechanical combination of the earth and the body. Let us suffer the falling body and the earth to dwindle in imagination to the size of atoms, and for the attraction of gravity let us substitute that of chemical affinity; we have then what is called a chemical combination. The effect of the union in this case also is the development of heat, and from the amount of heat generated we can infer the intensity of the atomic pull. Measured by ordinary mechanical standards, this is enormous. Mix eight pounds of oxygen with one of hydrogen, and pass a spark through the mixture: the gases instantly combine, their atoms rushing over the little distances which separate them. Take a weight of 47,000 pounds to an elevation of 1,000 feet above the earth's surface, and let it fall: the energy with which it will strike the earth will not exceed that of the eight pounds of oxygen atoms as they dash against one pound of hydrogen atoms to form water.—TYNDALL *Fragments of Science*, vol. i, ch. 1, p. 10. (A., 1897.)

1285. FORCE EXPENDED TO CONVERT WATER INTO STEAM—In order to pull apart the molecules of a pound of water, that is, convert it into steam, we must exert a mechanical power which is

the equivalent of 822,600 foot-pounds; that is, a power which would raise nearly four tons to the height of one hundred feet.—COOKE *New Chemistry*, lect. 1, p. 25. (A., 1899.)

1286. FORCE, FIELD OF, ABOUT A MAGNET—*Iron-filings Supposed Raving to Escape.*—Even more remarkable than this is his [Lucretius's] statement that iron-filings "will rave within brass basins" when the stone is placed beneath. This was the first perception of the field of force about a magnet, by noting not merely the effect of its attraction or repulsion exerted upon the pole of another magnet brought into it, but upon loose iron-filings free to dispose themselves therein along the lines of force. Then, under the astonished gaze of the poet, the particles of metal arranged themselves in the curious curves of the magnetic spectrum, and rose like bristles in front of the poles. And as he moved the stone beneath the brass basin which held them, he saw them fly from one side of it to the other, sometimes grouping themselves for an instant in dense bunches, then leaping apart and scattering all so incoherently and so wildly that it is small wonder that he regarded them as raving in their frantic desire to break away from the mysterious force.—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 2, p. 50. (J. W., 1898.)

1287. FORCE, LIVING, OF MOVING BODIES—*Vis Viva—Increase as Square of Velocity.*—In mechanics, the product of the mass of a moving body into the square of its velocity expresses what is called the *vis viva*, or living force. It is also sometimes called the "mechanical effect." If, for example, a cannon pointed to the zenith urge a ball upwards with twice the velocity imparted to a second ball, the former will rise to four times the height attained by the latter. If directed against a target, it will also do four times the execution. Hence the importance of imparting a high velocity to projectiles in war.—TYNDALL *Fragments of Science*, vol. i, ch. 1, p. 15. (A., 1897.)

1288. FORCE, MAGNETIC, LINES OF—*Iron-filings Grouped around Poles of Magnet.*—Placing a sheet of paper or glass over a bar magnet and showering iron-filings upon the paper, I notice a tendency of the filings to arrange themselves in determinate lines. They cannot freely follow this tendency, for they are hampered by the friction against the paper. They are helped by tapping the paper; each tap releasing them for a moment, and enabling them to follow their tendencies. . . . The aspect of these curves so fascinated Faraday that the greater portion of his intellectual life was devoted to pondering over them. He invested the space through which they run with a kind of materiality; and the probability is that the progress of science, by connecting the phenomena of magnetism with the luminiferous ether, will prove these "lines of force," as Faraday loved to call them, to represent a condition of this mysterious substratum of all radiant action.—TYNDALL *Lectures on Light*, lect. 3, p. 98. (A., 1898.)

1289. FORCE, MAN UTILIZES, BUT DOES NOT CREATE—*Property in Forces—Wind and Stream.*—We cannot create mechanical force, but we may help ourselves from the great storehouse of Nature. The brook and the wind which drive our mills, the forest and the coal-bed which supply our steam-engines and warm our rooms, are to us the bearers of a small proportion of the great natural supply which we draw upon for our purposes, and the action of which we can apply as we see fit. The possessor of a mill claims the gravity of the descending rivulet or the living force of a moving wind as his possession. These portions of the store of Nature are what give his property its chief value.—HELMHOLTZ *Interaction of Natural Forces*, p. 227. (Translated for *Scientific Side-Lights.*)

1290. FORCE MISAPPLIED—*Lubrication Converges Power on Work.*—So also with regard to the greasing of a saw by a carpenter. He applies his force with the express object of cutting through the wood. He wishes to overcome mechanical cohesion by the teeth of his saw, and, when it moves stiffly, the same amount of effort may produce a much smaller effect than when the implement moves without friction. But in what sense smaller? Not absolutely so, but smaller as regards the act of sawing. The force not expended in sawing is misapplied, not lost; it is converted into heat. Here again, if we could collect the heat engendered by the friction, and apply it to the urging of the saw, we should make good the precise amount of work which the carpenter, by neglecting the lubrication of his implement, had simply converted into another form of power.—TYNDALL *Heat a Mode of Motion*, lect. 1, p. 9. (A., 1900.)

1291. FORCE OF CRYSTALLIZATION—*Wonderful Property of Lifeless Matter.*—Gravitation . . . consists of an attraction of every particle of matter for every other particle. You know that planets and moons are held in their orbits by this attraction. But gravitation is a very simple affair compared to the force, or rather forces, of crystallization. For here the ultimate particles of matter, inconceivably small as they are, show themselves possessed of attractive and repellent poles, by the mutual action of which the shape and structure of the crystal are determined. In the solid condition the attracting poles are rigidly locked together; but if sufficient heat be applied the bond of union is dissolved, and in the state of fusion the poles are pushed so far asunder as to be practically out of each other's range. The natural tendency of the molecules to build themselves together is thus neutralized. This is the case with

water, which as a liquid is to all appearance formless. When sufficiently cooled the molecules are brought within the play of the crystallizing force, and they then arrange themselves in forms of indescribable beauty. —TYNDALL *Forms of Water,* § 88, p. 30. (A., 1899.)

1292. FORCE OF EXPANSION RESISTLESS—*Freezing Water Shatters Iron.*—The force with which water expands in freezing is all but irresistible. With the view of giving you an illustration of this fact, water has been confined in this iron bottle which is fully half an inch thick; the quantity of water being small, tho sufficient to fill the bottle. The bottle is closed by a screw firmly fixed in its neck. Two bottles thus prepared are placed in a copper vessel, and surrounded with a freezing mixture. They cool gradually, the water within them approaching its point of maximum density. No doubt, at this moment, a small vacuous space exists within each bottle. But soon the contraction ceases, and expansion sets in. The vacuous space is slowly filled, the water gradually changes from liquid to solid. To accomplish this change it requires more room, which the rigid iron refuses to grant. But its rigidity is powerless in the presence of these molecular forces, and the sound you now hear indicates that the bottle is shivered by the crystallizing molecules. The other bottle follows; and here are the fragments of the vessels, showing their thickness, and impressing you with the vastness of the expansive force by which they have been thus riven. While I have been speaking, you have heard a louder explosion in front of the table. That was due to the rupture of a thick bombshell kindly prepared for me at Woolwich by Professor Abel. It was filled with water, screwed up tight, placed in a bucket, and surrounded by a freezing mixture. Taken from the mixture, the fragments of the bomb are placed here before you. Care must be taken in repeating this experiment to cover the bucket with a thick cloth. Wanting such protection I have seen the stopper of a broken bomb projected nearly as high as this ceiling.—TYNDALL *Heat a Mode of Motion,* lect. 4, p. 105. (A., 1900.)

1293. FORCE OF GRAVITY AT THE SUN'S SURFACE—The sun attracts objects at its surface twenty-seven times more strongly than the earth does. This calculation would be the same for the investigation of gravity at the surface of all the planets. A human body, if it could be transported to the sun, would be immediately flattened by gravity into a thin leaf. But, in point of fact, it would be vaporized long before it could arrive there.—FLAMMARION *Popular Astronomy,* bk. iii, ch. 2, p. 242. (A.)

1294. ——— ——— *All Earthly Adjustments Changed.*—If we calculate the force of gravity at the sun's surface, which is easily done by dividing its mass, 330,000, by the square of 109½ (the number of times the sun's diameter exceeds the earth's), we find it to be 27½ times as great as on the earth; a man who on the earth would weigh 150 pounds would there weigh nearly two tons; and, even if the footing were good, would be unable to stir. A body which at the earth falls a little more than 16 feet in a second would there fall 443. A pendulum which here swings once a second would there oscillate more than five times as rapidly, like the balance-wheel of a watch—quivering rather than swinging.—YOUNG *The Sun,* ch. 1, p. 41. (A., 1898.)

1295. FORCE OF RUNNING WATER—*Sand and Pebbles Give Cutting Power.*—The mechanical force exerted by running water in undermining cliffs and rounding off the angles of hard rock is mainly due to the intermixture of foreign ingredients. Sand and pebbles, when hurried along by the violence of the stream, are thrown against every obstacle lying in their way, and thus a power of attrition is acquired, capable of wearing through the hardest silicious stones, on which water alone could make no impression.—LYELL *Geology,* ch. 14, p. 204. (A., 1854.)

1296. FORCE, ORIGIN AND EXTENSION OF IDEA OF—*Power an Essential Element of Causation.*—When, however, we not only look at bodies in motion, but try to resist their motion by an exertion of our own, or use a similar exertion in giving motion to a body at rest, we are led, by our own sense of effort in making it, to an entirely new conception, that of force; and no advance in the philosophy of science has been greater than that which has of late years extended the notion of force, from the agency which produces or resists the motion of masses, to the agencies which are concerned in producing the molecular changes which we refer to heat, light, electricity, magnetism, etc. The man of science of the present day is thus enabled to attach a distinct idea to that efficient causation which logicians have continually denied, but which the common sense of mankind has universally recognized. When the cause of any event is spoken of, in common parlance, we certainly attach to the term the idea of power, at the same time that we include the notion of the conditions under which that power operates; and this view of the case can be shown to be scientifically correct.—CARPENTER *Mental Physiology,* ch. 20, p. 693. (A., 1900.)

1297. FORCE, THE DIRECTION OF—*Importance of Initiative—Early Metallurgy—Heat-engines.*—When a savage softened or melted a lump of copper in a blaze, his act was one of direction rather than of execution: to have warmed the metal by repeated blows would have been a toilsome and unrewarded task; while to place the copper in the flame and duly to remove it

was labor of an unexacting and most fruitful kind. So, too, when heat-engines of constantly improved types came into the mines, the shops, and factories of the world, and were last of all adapted to transportation, the work that a skilful man could direct became immensely greater and bolder than the task he could perform by dint of exerting his own muscles. In this passing to more and more of initiative consists an important phase of civilization.—ILES *Flame, Electricity, and the Camera*, ch. 5, p. 63. (D. & McC., 1900.)

1298. FORCES, ELEMENTAL, MADE TO WORK FOR MAN—*Transformation of Industry—From Shadoof to Water-wheel.*—In the period of ancient civilization there appear the beginnings of that immense change which is remodeling modern life, by inventions which set the forces of Nature to do man's heavy work for him. This great change seems to have been especially brought on by contrivances to save the heavy toil of watering the fields. A simple hand-labor contrivance of this kind is the shadoof of the Nile Valley, where a long pole with a counterpoise at one end is supported on posts, and carries a bucket hanging to the longer end to dip up water from below. . . . For irrigation, it was mechanically an improvement on this to set a gang of slaves to turn a great wheel with buckets or earthern jars at its circumference, which rose full from the water below, and as they turned over emptied themselves into a trough at a higher level. But when such a wheel was built to dip in a running stream, then the current itself would turn the wheel, and thus would come into existence the noria, or irrigating water-wheel, often mentioned in ancient literature, and to be seen still at work both in the East and in Europe. By these or some similar steps of invention the water-wheel was made a source of power for doing other work, such as grinding corn, instead of the women at the quern or the slaves at the treadmill, or the mill-horse in his everlasting round. As the Greek epigram says, "Cease your work, ye maids who labored at the mills, sleep and let the birds sing to the returning dawn, for Demeter has bidden the water-nymphs to do your task; obedient to her call, they throw themselves on the wheel and turn the axle and the heavy mill."—TYLOR *Anthropology*, ch. 8, p. 203. (A., 1899.)

1299. FORCES, MATERIAL AND MENTAL—*Every Force Perhaps a Manifestation of Will.*—Undoubtedly the first thought which suggests itself to the mind is, that a material force and a moral or intellectual force are essentially different in kind—not subject to conditions the same, or even similar. But are we sure of this? Are we sure that the forces which we call material are not, after all, but manifestations of mental energy and will? We have already seen that such evidence as we have is all tending the other way. The conclusions forced upon us have been these: First, that the more we know of Nature the more certain it appears that a multiplicity of separate forces does not exist, but that all her forces pass into each other, and are but modifications of some one force which is the source and center of the rest; secondly, that all of them are governed in their mutual relations by principles of arrangement which are purely mental; thirdly, that of the ultimate seat of force in any form we know nothing directly; and fourthly, that the nearest conception we can ever have of force is derived from our own consciousness of vital power.—ARGYLL *Reign of Law*, ch. 6, p. 164. (Burt.)

1300. FORCES OF NATURE NOT BLIND—*The Blindness Is in Man—Snow-crystals.*—When snow is produced in calm air, the icy particles build themselves into beautiful stellar shapes, each star possessing six rays. There is no deviation from this type, tho in other respects the appearances of the snow-stars are infinitely various. . . . It is worth pausing to think what wonderful work is going on in the atmosphere during the formation and descent of every snow-shower: what building power is brought into play! and how imperfect seem the productions of human minds and hands when compared with those formed by the blind forces of Nature!

But who ventures to call the forces of Nature blind? In reality, when we speak thus, we are describing our own condition. The blindness is ours; and what we really ought to say, and to confess, is that our powers are absolutely unable to comprehend the origin or the end of the operations of Nature.—TYNDALL *Forms of Water*, § 89, p. 31. (A., 1899.)

1301. FORCES, TITANIC, OF NATURE—*Rocks Ground to Impalpable Powder.*—During their upward discharge and downward fall, the cindery fragments are by attrition continually reduced to smaller dimensions. The noise made by these fragments, as they strike against one another in the air during their rise and fall, is one of the most noteworthy accompaniments of volcanic eruptions. It has been noticed that in many cases there is a constant diminution in the size of the fragments ejected during a volcanic outburst, this being doubtless due to the friction of the masses as they are ejected and reejected from the vent. Thus it is related by Mr. Poulett Scrope, who watched the Vesuvian eruption of 1822, which lasted for nearly a month, that during the earlier stages of the outburst fragments of enormous size were thrown out of the crater, but by constant reejection these were gradually reduced in size, till at last only the most impalpable dust issued from the vent. This dust filled the atmosphere, producing in the city of Naples "a darkness that might be felt,"

and so excessively finely divided was it that it penetrated into all drawers, boxes, and the most closely fastened receptacles, filling them completely.—JUDD *Volcanoes*, ch. 4, p. 68. (A., 1899.)

1302. FORCES UNSEEN IN THE AIR WE BREATHE—*Mountains Precipitate Invisible Vapor.*—The atmospheric change [after crossing the Simplon to the Italian lakes] was wonderful; and still the clear air which we enjoyed below was the selfsame air that heaped clouds and snow upon the mountains. It came across the heated plains of Lombardy charged with moisture, but the moisture was in the transparent condition of true vapor, and hence invisible. Tilted by the mountains, the air rose, and as it expanded it became chilled, and as it became chilled it discharged its vapor as visible cloud, the globules of which swelled by coalescence into raindrops on the mountain flanks, or were frozen to snow upon the mountain.—TYNDALL *Hours of Exercise in the Alps*, ch. 22, p. 261. (A., 1898.)

1303. FORCES, UNSEEN, POWER OF—*Bonds of Wire or Steel to Equal Sun's Attraction.*—As for the attraction between the sun and earth, it amounts to thirty-six hundred quadrillions of tons: in figures, 36 followed by seventeen ciphers. On this point we borrow an impressive illustration from a careful calculation by Mr. C. B. Warring. We may imagine gravitation to cease, and to be replaced by a material bond of some sort, holding the earth to the sun and keeping her in her orbit. If now we suppose this connection to consist of a web of steel wires, each as large as the heaviest telegraph-wires used, then to replace the sun's attraction these wires would have to cover the whole sunward hemisphere of our globe about as thickly as blades of grass upon a lawn. It would require nine to each square inch. Putting it a little differently, the attraction between the sun and earth is equal to the breaking strain of a steel rod about 3,000 miles in diameter.—YOUNG *The Sun*, ch. 1, p. 41. (A., 1898.)

1304. FORCES, VITAL AND MATERIAL—*Terms Ill-understood.*—What is a vital force? It is something which we cannot see, but of whose existence we are as certain as we are of its visible effects—nay, which our reason tells us precedes and is superior to these. We often speak of material forces as if we could identify any kind of force with matter. But this is only one of the many ambiguities of language. All that we mean by a material force is a force which acts upon matter, and produces in matter its own appropriate effects. We must go a step further, therefore, and ask ourselves, what is force? What is our conception of it? What idea can we form, for example, of the real nature of that force the measure of whose operation has been so exactly ascertained—the force of gravitation? It is invisible—imponderable—all our words for it are but circumlocutions to express its phenomena or effects.—ARGYLL *Reign of Law*, ch. 2, p. 71. (Burt.)

1305. FORCES WORKING IN UNISON—*Light, Heat, and Electricity Inseparably Connected with Motion and Life.*—Light, and radiating heat, which is inseparable from it, constitute a main cause of motion and organic life, both in the non-luminous celestial bodies and on the surface of our planet. Even far from its surface, in the interior of the earth's crust, penetrating heat calls forth electromagnetic currents, which exert their exciting influence on the combinations and decompositions of matter—on all formative agencies in the mineral kingdom—on the disturbance of the equilibrium of the atmosphere—and on the functions of vegetable and animal organisms. If electricity moving in currents develops magnetic forces, and if, in accordance with an early hypothesis of Sir William Herschel, the sun itself is in the condition of "a perpetual northern light" (I should rather say of an electromagnetic storm), we should seem warranted in concluding that solar light, transmitted in the regions of space by vibrations of ether, may be accompanied by electromagnetic currents.—HUMBOLDT *Cosmos*, vol. iii, p. 34. (H., 1897.)

1306. FOREST, PRIMEVAL—*Brazil—Terra del Fuego—Silent Message of the God of Nature.*—Among the scenes which are deeply impressed on my mind, none exceed in sublimity the primeval forests undefaced by the hand of man; whether those of Brazil, where the powers of life are predominant, or those of Terra del Fuego, where death and decay prevail. Both are temples filled with the varied productions of the God of Nature—no one can stand in these solitudes unmoved, and not feel that there is more in man than the mere breath of his body.—DARWIN *Naturalist's Voyage around the World*, ch. 21, p. 503. (A., 1898.)

1307. FORESTS BURIED UNDER DRIFT—*The Elephant, Rhinoceros, and Hippopotamus Once Ranged in England.*—At one of the most charming spots on the coast of Norfolk, Cromer, you will see the boulder-clay forming a vast mass, which lies upon the chalk, and must consequently have come into existence after it. I have spoken of the boulder-clay and drift as resting upon the chalk. That is not strictly true. Interposed between the chalk and the drift is a layer containing vegetable matter. But that layer tells a wonderful history. It is full of stumps of trees standing as they grew. Fir-trees are there with their cones, and hazel-bushes with their nuts; there stand the stools of oak- and yew-trees, beeches and alders. Hence this stratum is appropriately called the "forest-bed."

It is obvious that the chalk must have been upheaved and converted into dry land before the timber trees could grow upon it.

As the boles of some of these trees are from two to three feet in diameter, it is no less clear that the dry land thus formed remained in the same condition for long ages. And not only do the remains of stately oaks and well-grown firs testify to the duration of this condition of things, but additional evidence to the same effect is afforded by the abundant remains of elephants, rhinoceroses, hippopotamuses, and other great wild beasts.—HUXLEY *Lay Sermons,* serm. 9, p. 193. (G. P. P., 1899.)

1308. FORESTS BURIED UNDER ICE —*Return after Centuries to the Sunlight.*—The glacier, now in its full strength, advances from the extremity of the valley that sheltered its youth and guided its early life, and invades the piedmont plain. The low lands are densely forested. Majestic spruce-trees and aged moss-covered hemlocks stand in thick, serrate ranks across the glacier's path, but are mowed down as easily as the grass before a scythe. Crushed, broken, and splintered, the trunks are piled in huge confused heaps and overriden and buried by the slow but resistless march of the ice. Where the waters flowing from the glacier are abundantly loaded with sand and gravel, they build alluvial deposits about its margin. The streams in their passage over these alluvial cones subdivide and send off distributaries into the forest to the right and left, and the trees are surrounded and buried by sand and gravel while yet standing. A fringe of dead trees, in part denuded of their branches, marks the areas where the stream-borne deposits have made recent conquests. Under these conditions the glacier advances over the buried forests, and all vestiges of its existence are blotted out. Centuries later the still erect trunks may be revealed [as now at Muir Glacier, Alaska].—RUSSELL *Glaciers of North America,* ch. 10, p. 199. (G. & Co., 1897.)

1309. FORESTS BURIED UNDER STRATA—*Gradual Subsidence of Earth's Crust.*—The supposition of a gradual subsidence over large areas is by no means improbable. We have the clearest proof that a movement of this kind is possible, in the upright trees buried under strata many thousand feet in thickness; we have also every reason for believing that there are now large areas gradually sinking, in the same manner as others are rising. And when we consider how many parts of the surface of the globe have been elevated within recent geological periods, we must admit that there have been subsidences on a corresponding scale, for otherwise the whole globe would have swollen. It is very remarkable that Sir C. Lyell, even in the first edition of his "Principles of Geology," inferred that the amount of subsidence in the Pacific must have exceeded that of elevation, from the area of land being very small relatively to the agents there tending to form it, namely the growth of coral and volcanic action.—DARWIN *Coral Reefs,* ch. 5, p. 128. (A., 1900.)

1310. FORGETFULNESS, HUMAN—*Changes in Earth Unrecorded—A Moslem Parable.*—A manuscript work, entitled the "Wonders of Nature," is preserved in the Royal Library at Paris, by an Arabian writer, Mohammed Kazwini, who flourished in the seventh century of the Hegira, or at the close of the thirteenth century of our era. Besides several curious remarks on aerolites, earthquakes, and the successive changes of position which the land and sea have undergone, we meet with the following beautiful passage which is given as the narrative of Kidhz, an allegorical personage: "I passed one day by a very ancient and wonderfully populous city, and asked one of its inhabitants how long it had been founded. 'It is indeed a mighty city,' replied he; 'we know not how long it has existed, and our ancestors were on this subject as ignorant as ourselves.' Five centuries afterwards, as I passed by the same place, I could not perceive the slightest vestige of the city. I demanded of a peasant, who was gathering herbs upon its former site, how long it had been destroyed. 'In sooth a strange question!' replied he. 'The ground here has never been different from what you now behold it.' 'Was there not of old,' said I, 'a splendid city here?' 'Never,' answered he, 'so far as we have seen, and never did our fathers speak to us of any such.' On my return there, 500 years afterwards, I found the sea in the same place, and on its shores were a party of fishermen, of whom I inquired how long the land had been covered by the waters. 'Is this a question,' said they, 'for a man like you? This spot has always been what it is now.' I again returned 500 years afterwards, and the sea had disappeared; I inquired of a man who stood alone upon the spot, how long ago this change had taken place, and he gave me the same answer as I had received before. Lastly, on coming back again after an equal lapse of time, I found there a flourishing city, more populous and more rich in beautiful buildings than the city I had seen the first time, and when I would fain have informed myself concerning its origin, the inhabitants answered me, 'Its rise is lost in remote antiquity; we are ignorant how long it has existed, and our fathers were on this subject as ignorant as ourselves.'"—LYELL *Principles of Geology,* bk. i, ch. 3, p. 19. (A., 1854.)

1311. FORMATION OF ROCKS IN THE PRESENT ERA—*Nature Seen at Work.*—Some of the springs which issue from the ichthyolite beds along the shores of the Moray Frith are largely charged, not with iron, . . . but with carbonate of lime. When employed for domestic purposes, they choke up, in a few years, with a stony deposition, the spouts of tea-kettles. On a

similar principle, they plug up their older channels, and then burst out in new ones; nor is it uncommon to find among the cliffs little hollow recesses, long since divested of their waters by this process, that are still thickly surrounded by coral-like incrustations of moss and lichens, grass and nettle-stalks, and roofed with marble-like stalactites. I am acquainted with at least one of these springs of very considerable volume, and dedicated of old to an obscure Roman Catholic saint, whose name it still bears (St. Bennet), which presents phenomena not unworthy the attention of the young geologist. It comes gushing from out the ichthyolite bed, where the latter extends, in the neighborhood of Cromarty, along the shores of the Moray Frith: and after depositing in a stagnant morass an accumulation of a grayish-colored and partially consolidated travertin, escapes by two openings to the shore, where it is absorbed among the sand and gravel. A storm about three years ago swept the beach several feet beneath its ordinary level, and two little moles of conglomerate and sandstone, the work of the spring, were found to occupy the two openings. Each had its fossils—comminuted sea-shells and stalks of hardened moss; and in one of the moles I found embedded a few of the vertebral joints of a sheep. It was a recent formation on a small scale, bound together by a calcareous cement furnished by the fish-beds of the inferior Old Red Sandstone, and composed of sand and pebbles, mostly from the granitic gneiss of the neighboring hill, and organisms, vegetable and animal, from both the land and the sea.—MILLER *Old Red Sandstone*, ch. 10, p. 184. (G. & L., 1851.)

1312. FORMATION OF SCIENTIFIC THEORIES—*Mind Demands a Cause.*—Scientific theories, in the first place, take their rise in the desire of the mind to penetrate to the sources of phenomena. From its infinitesimal beginnings, in ages long past, this desire has grown and strengthened into an imperious demand of man's intellectual nature. It long ago prompted Cæsar to say that he would exchange his victories for a glimpse of the sources of the Nile: it wrought itself into the atomic theories of Lucretius; it impels Darwin to those daring speculations which of late years have so agitated the public mind. But in no case in framing theories does the imagination create its materials. It expands, diminishes, molds, and refines, as the case may be, materials derived from the world of fact and observation.—TYNDALL *Lectures on Light*, lect. 3, p. 95. (A., 1898.)

1313. FORMATION OF WATER FROM GAS—*Mechanics of Explosion—Speed of Sound.*—Let us fill a soap-bubble with oxygen and hydrogen gases in the proportion of two parts of hydrogen to one of oxygen. If we ignite it the result will be an explosion. When the ignition takes place there is a sudden generation of heat, which suddenly expands the air, causing it to be highly rarefied at the point of explosion. The air immediately surrounding it is driven violently outward in every direction. The first layer of air-particles, surrounding the bubble, is driven against the second, and then swings back to its place, for the force that drove it outward is no longer present. The second layer swings against the third, and the third against the fourth, and so on; each layer after making its excursion outward returns to its original position. The air-particles are not fired at the ear as from a gun; they simply vibrate to and fro. The sound-pulse moves outward like an expanding globe at the rate of about 1,100 feet per second in air, the speed depending upon the medium through which it travels.—ELISHA GRAY *Nature's Miracles*, vol. ii, ch. 6, p. 59. (F. H. & H., 1900.)

1314. FORMS OF LIFE LOST AND REINTRODUCED—*Remains of Extinct Race of Horses in South America.*—In the pampean deposit at the Bajada [Entre Rios, South America] I found . . . [with remains of the mastodon, etc.] also one tooth of a horse, in the same stained and decayed state. This latter tooth greatly interested me, and I took scrupulous care in ascertaining that it had been embedded contemporaneously with the other remains; for I was not then aware that amongst the fossils from Bahia Blanca there was a horse's tooth hidden in the matrix: nor was it then known with certainty that the remains of horses are common in North America. Mr. Lyell has lately brought from the United States a tooth of a horse; and it is an interesting fact that Professor Owen could find in no species, either fossil or recent, a slight but peculiar curvature characterizing it, until he thought of comparing it with my specimen found here: he has named this American horse *Equus curvidens*. There is good evidence against any horse living in America at the time of Columbus. Certainly it is a marvelous fact in the history of the mammalia, that in South America a native horse should have lived and disappeared, to be succeeded in after-ages by the countless herds descended from the few introduced with the Spanish colonists!—DARWIN *Naturalist's Voyage around the World*, ch. 7, p. 130. (A., 1898.)

1315. FORMS OF LIFE, SEEMINGLY INDEPENDENT, IN THE BLOOD—*White Cells [Leucocytes] Battling with Germs of Disease.*—We possess in our blood millions of little living bodies, which are, in a sense, independent of us—autonomous subjects, as it were, of the body at large. They are not under our control in any sense, but live and move, and discharge their duties as freely as if they recognized no right or title of their possessor to question their acts. . . . Watching one of these living particles on a microscope slide especially kept at the

blood's own temperature, we can see it literally to flow from one shape to another. It imitates in this way the movements of many an animalcule in the pools. We may also see our independent white corpuscle seizing and digesting food-particles, as if, in very truth, it were an independent animalcule. This power of feeding, we shall see, is an important characteristic of our wandering particle. . . . For it is now a matter of certainty that among all the servants of our bodies we possess none more active, none more faithful, and none more necessary than our wandering cells. . . . There is a battle between our white cells [leucocytes] and the germs of disease. If the latter are victorious, we fall ill of the fever or other ailment; if we escape the fever, our immunity is due to the victory of our microscopic friends over the germs.—WILSON *Glimpses of Nature*, ch. 23, p. 74. (Hum., 1892.)

1316. FOSSILS AS MEMENTOES OF THE PAST—*Surpass Coins and Medals in Interest.*—"However trivial a thing," he [Robert Hooke, 1688] says, "a rotten shell may appear to some, yet these monuments of Nature are more certain tokens of antiquity than coins or medals, since the best of those may be counterfeited or made by art and design, as may also books, manuscripts, and inscriptions, as all the learned are now sufficiently satisfied has often been actually practised," etc.; "and tho it must be granted that it is very difficult to read them (the records of Nature) and to raise a chronology out of them, and to state the intervals of the time wherein such or such catastrophes and mutations have happened, yet it is not impossible."—LYELL *Principles of Geology*, pt. i, ch. 3, p. 27. (A., 1854.)

1317. FOSSILS, MAGICAL VIRTUES ATTRIBUTED TO—*"Unicorn's Horn"—Human Remains in Ancient Caves—Man Contemporary with Extinct Animals.*—The existence of fossil remains of animals in the caves of Europe has long been known. In the sixteenth and seventeenth centuries they were, under the name of "*ebur fossile*," or unicorn's horn, greatly esteemed as a medicine, and were obtained in great quantity from the caves of the Hartz district and of Hungary and Franconia. Baumann's Hole in the Hartz had already become famous at the close of the seventeenth century, and descriptions of other caves and of their contents followed at intervals, until at last a new branch of investigation sprang up, the importance of which can hardly be exaggerated when its bearings upon the early history of man are considered. It was long, however, before the possibility of man's existence contemporaneously with the extinct animals found in some of the oldest caves was entertained by the majority of scientific men; but the doubt was finally set at rest in 1858 upon the discovery of undoubted human relics in the celebrated Brixham Cave in Devonshire.—DALLAS *Nature-Studies*, p. 45. (Hum., 1888.)

1318. FOSSILS OF THE COAL PERIOD—*Evidence of Warm and Uniform Climate.*—The flora of the coal appears to indicate a uniform and mild temperature in the air, while the fossils of the contemporaneous mountain limestone, comprising abundance of lamelliferous corals, large-chambered cephalopods, and *Crinoidea*, naturally lead us to infer a considerable warmth in the waters of the northern sea of the Carboniferous period. So also in regard to strata older than the coal, they contain in high northern latitudes mountain masses of corals which must have lived and grown on the spot, and large-chambered univalves, such as *Orthocerata* and *Nautilus*, all seeming to indicate, even in regions bordering on the arctic circle, the former prevalence of a temperature more elevated than that now prevailing.

The warmth and humidity of the air, and the uniformity of climate, both in the different seasons of the year and in different latitudes, appear to have been most remarkable when some of the oldest of the fossiliferous strata were formed.—LYELL *Principles of Geology*, bk. i, ch. 6, p. 91. (A., 1854.)

1319. FOSSILS OF THE OLD RED SANDSTONE—*Fantastic Forms That Have Become Extinct.*—Half my closet walls are covered with the peculiar fossils of the Lower Old Red Sandstone; and certainly a stranger assemblage of forms have rarely been grouped together—creatures whose very type is lost, fantastic and uncouth, and which puzzle the naturalist to assign them even their class—boat-like animals, furnished with oars and a rudder—fish-plated over, like the tortoise, above and below, with a strong armor of bone, and furnished with but one solitary rudder-like fin; other fish less equivocal in their form, but with the membranes of their fins thickly covered with scales—creatures bristling over with thorns; others glistening in an enameled coat, as if beautifully japanned—the tail, in every instance among the less equivocal shapes, formed not equally, as in existing fish, on each side the central vertebral column, but chiefly on the lower side—the column sending out its diminished vertebræ to the extreme termination of the fin. All the forms testify of a remote antiquity—of a period whose "fashions have passed away." The figures on a Chinese vase or an Egyptian obelisk are scarce more unlike what now exists in Nature than the fossils of the Lower Old Red Sandstone.—MILLER *The Old Red Sandstone*, ch. 2, p. 30. (G. & L., 1851.)

1320. FOUNDERS OF PHYSICAL SCIENCE—*Arabs Deserve the Title.*—The Arabs, a people of Semitic origin, partially dispelled the barbarism which had shrouded Europe for upward of two hundred years after the

storms by which it had been shaken, from the aggressions of hostile nations. The Arabs lead us back to the imperishable sources of Greek philosophy; and besides the influence thus exercised on scientific cultivation, they have also extended and opened new paths in the domain of natural investigation. . . . The Arabs are to be regarded as the actual founders of physical science, considered in the sense which we now apply to the words.

It is undoubtedly extremely difficult to associate any absolute beginning with any definite epoch of time in the history of the mental world and of the intimately connected elements of thought. Individual luminous points of knowledge, and the processes by which knowledge was gradually attained, may be traced scattered through very early periods of time. How great is the difference that separates Dioscorides, who distilled mercury from cinnabar, from the Arabian chemist Dscheber; how widely is Ptolemy, as an optician, removed from Alhazen; but we must, nevertheless, date the foundation of the physical sciences, and even of natural science, from the point where new paths were first trodden by many different investigators, altho with unequal success.—Humboldt *Cosmos*, vol. ii, pt. ii, pp. 201-209. (H., 1897.)

1321. FRAGMENT OF ANCIENT EARTH—*Mountain Carved from Vaster Mass.*—How this wondrous mountain [the Matterhorn] has been formed will be the subject of subsequent inquiry. It is not a spurt of molten matter ejected from the nucleus of the earth; from base to summit there is no truly igneous rock. It has no doubt been upraised by subterranean forces, but that it has been lifted as an isolated mass is not conceivable. It must have formed part of a mighty boss or swelling, from which the mountain was subsequently sculptured.—Tyndall *Hours of Exercise in the Alps*, ch. 14, p. 164. (A., 1898.)

1322. FRAGMENT PRESERVED FROM LOST WORK OF ARISTOTLE—*Description of Natural Beauty—An Argument for Creative Power.*—We possess a genuine fragment which Cicero ["De Natura Deorum," ii, 37] has preserved to us from a lost work of Aristotle. It runs thus: "If there were beings who lived in the depths of the earth, in dwellings adorned with statues and paintings and everything which is possessed in rich abundance by those whom we esteem fortunate; and if these beings could receive tidings of the power and might of the gods, and could then emerge from their hidden dwellings through the open fissures of the earth to the places which we inhabit; if they could suddenly behold the earth, and the sea, and the vault of heaven; could recognize the expanse of the cloudy firmament, and the might of the winds of heaven, and admire the sun in its majesty, beauty, and radiant effulgence; and, lastly, when night veiled the earth in darkness, they could behold the starry heavens, the changing moon, and the stars rising and setting in the unvarying course ordained from eternity—they would surely exclaim, 'There are gods, and such great things must be the work of their hands.'" It has been justly observed that this passage is alone sufficient to corroborate Cicero's opinion of "the golden flow of Aristotle's eloquence," and that his words are pervaded by something of the inspired force of Plato's genius. Such a testimony to the existence of the heavenly powers, drawn from the beauty and stupendous greatness of the works of creation, is rarely to be met with in the works of antiquity.—Humboldt *Cosmos*, vol. ii, pt. i, p. 29. (H., 1897.)

1323. FREEDOM AND INDEPENDENCE OF THE SEXES IN AMERICA—*Youthful Acquaintanceships—Coeducation.*—It has been given especially to one nation to lead the world in its assault upon this mistaken law [of separation of sexes in youth], and to demonstrate to mankind that in the unconstrained and artless relations of youth lie higher safeguards than the polite conventions of society can afford. The people of America have proved that the blending of the sweet currents of different family lives in social intercourse, in recreation, and—most original of all—in education, can take place freely and joyously without any sacrifice of man's reverence for woman, or woman's reverence for herself; and, springing out of these naturally mingled lives, there must more and more come those sacred and happy homes which are the surest guaranties for the moral progress of a nation. So long as the first concern of a country is for its homes, it matters little what it seeks second or third.—Drummond *Ascent of Man*, ch. 9, p. 304. (J. P., 1900.)

1324. FREEDOM AND NECESSITY—*Freedom To Do Right.*—I protest that if some great Power would agree to make me always think what is true and do what is right, on condition of being turned into a sort of clock and wound up every morning before I got out of bed, I should instantly close with the offer. The only freedom I care about is the freedom to do right; the freedom to do wrong I am ready to part with on the cheapest terms to any one who will take it of me.—Huxley *Lay Sermons*, serm. 14, p. 340. (G. P. P., 1899.)

1325. FREEDOM NOT ABSOLUTE—*Exemption from Some Special Restraint.*—Is man's voluntary agency a delusion, or is it, on the contrary, just what we feel it to be, and is it only from misconception of its nature that we puzzle over its relation to law? We speak, and speak truly, of our wills being free; but free from what? It seems to be forgotten that freedom is not an absolute, but a relative term. There is no such thing existing as absolute freedom—

that is to say, there is nothing existing in the world, or possible even in thought, which is absolutely alone—entirely free from inseparable relationship to some other thing or things. Freedom, therefore, is only intelligible as meaning the being free from some particular kind of restraint.—ARGYLL *Reign of Law*, ch. 6, p. 179. (Burt.)

1326. FREEDOM OF CHANGE—*Honesty and Truth Better than Consistency.*—He [Cope] has been much blamed on account of the constant changes of his views and because he was inconsistent. Unquestionably he did change his views very often. Doubtless some of those changes were necessitated by too great haste in formulation and too great rashness in publication. The freedom to change which he exercised . . . was an offset to his rashness. He exercised a proper scientific spirit in refusing to be always consistent at the expense of truth.—GILL *Address in Memory of Edward Drinker Cope* in *Proceedings of Amer. Assoc. for Advancement of Science*, vol. xlvi, 1897.

1327. FREEDOM OF SAVAGES AN ILLUSION—*Slavery to Barbarous Customs—Irrational Demands on Devotee.*—The truth is that nowhere is the evidence of development in a wrong direction so strong as in the many customs of savage and barbarous nations which are more or less directly connected with religion. The idea has long been abandoned that the savage lives in a condition of freedom as compared with the complicated obligations imposed by civilization. Savages, on the contrary, are under the tyranny of innumerable customs which render their whole life a slavery from the cradle to the grave. And what is most remarkable is the irrational character of most of these customs, and the difficulty of even imagining how they can have become established. They bear all the marks of an origin far distant in time—of a connection with doctrines which have been forgotten, and of conceptions which have run, as it were, to seed. They bear, in short, all the marks of long attrition, like the remnants of a bed of rock which has been broken up at a distant epoch of geological time, and has left no other record of itself than a few worn and incoherent fragments in some far-off conglomerate. Just as these fragments are now held together by common materials which are universally distributed, such as sand or lime, so the worn and broken fragments of old religions are held together, in the shape of barbarous customs, by those common instincts and aspirations of the human mind which follow it in all its stages, whether of growth or of decay.—ARGYLL *Unity of Nature*, ch. 12, p. 285. (Burt.)

1328. FREEMAN, MORAL, VS. MORAL SLAVE *(John viii, 32-36)*—*Avoiding Evil through Love of Good.*—Spinoza long ago wrote in his "Ethics" that anything that a man can avoid under the notion that it is bad he may also avoid under the notion that something else is good. He who habitually acts *sub specie mali*, under the negative notion, the notion of the bad, is called a slave by Spinoza. To him who acts habitually under the notion of good he gives the name of freeman.—JAMES *Talks to Teachers*, ch. 15, p. 194. (H. H. & Co., 1900.)

1329. FREEZING BY RADIATION—*Formation of Artificial Ice in Bengal.*—Wells was the first to explain the formation, artificially, of ice in Bengal, where the substance is never formed naturally. Shallow pits are dug, which are partially filled with straw, and on the straw flat pans containing water are exposed to the clear firmament. The water is a powerful radiant, and sends off its heat copiously into space. The heat thus lost cannot be supplied from the earth—this source being cut off by the non-conducting straw. Before sunrise a cake of ice is formed in each vessel. This is the explanation of Wells, and it is, no doubt, the true one. I think, however, it needs supplementing. It appears, from the description, that the condition most suitable for the formation of ice is not only a clear air, but a dry air. The nights, says Sir Robert Barker, most favorable for the production of ice, are those which are clearest and most serene, and *in which very little dew appears after midnight.* The italicized phrase is very significant. To produce the ice in abundance, the atmosphere must not only be clear, but it must be comparatively free from aqueous vapor. When the straw on which the pans were laid became wet, it was always changed for dry straw; and the reason Wells assigned for this was, that the straw, by being wetted, was rendered more compact and efficient as a conductor. This may have been the case, but it is also certain that the vapor rising from the wet straw, and overspreading the pans like a screen, would check the chill and retard the congelation.—TYNDALL *Heat a Mode of Motion*, lect. 17, p. 500. (A., 1900.)

1330. FREEZING BY RAREFACTION—Joseph Henry read a communication [March 2, 1825] on the production of cold by the rarefaction of air, accompanied with experiments.

One of these experiments most strikingly illustrated the great reduction of temperature which takes place on the sudden rarefaction of condensed air. Half a pint of water was poured into a strong copper vessel, of a globular form, and having a capacity of five gallons; a tube of one-fourth of an inch in caliber, with a number of holes near the lower end and a stop-cock attached to the other extremity, was firmly screwed into the neck of the vessel; the lower end of the tube dipped into the water, but a number of the holes were above the surface of the liquid, so that a jet of air mingled with water might be thrown from the fountain. The apparatus was then charged with condensed air, by means of a powerful condensing-pump, until the pressure was esti-

mated at nine atmospheres; during the condensation the vessel became sensibly warm. After suffering the apparatus to cool down to the temperature of the room, the stop-cock was opened; the air rushed out with great violence, carrying with it a quantity of water, which was instantly converted into snow; after a few seconds the tube became filled with ice, which almost entirely stopped the current of air. The neck of the vessel was then partially unscrewed, so as to allow the condensed air to rush out around the sides of the screw; in this state the temperature of the whole atmosphere was so much reduced as to freeze the remaining water in the vessel; the stop-cock and tube at the same time became so cold that the fingers adhered to them, in the same manner that they are sometimes found to stick to the latch of a door on an intensely cold morning. This experiment was exhibited to the Institute within six feet of a large stove, and in a room the temperature of which was not less than eighty degrees of Fahrenheit's thermometer.—HENRY *Proceedings of Albany Institute*, vol. i, p. 39.

1331. FREEZING NOT DESTRUCTIVE OF MICRO-ORGANISMS—*Bacteria in Ice.*—Ice contains bacteria in varying quantities from 20 per c. c. to 10,000 or more. Nor is variation in number affected alone by the condition of the water, for samples collected from one and the same place differ widely. The quality follows in large measure the standard of the water.—NEWMAN *Bacteria*, ch. 6, p. 238. (G. P. P., 1899.)

1332. FREEZING, SUDDEN, OF NORTHERN RIVER—*Wild Oxen Frozen in Tibet in Act of Swimming.*—A herd of mammoths returning from their summer pastures in the north may have been surprised, while crossing a stream, by the sudden congelation of the waters. The missionary Huc relates, in his travels in Tibet in 1846, that, after many of his party had been frozen to death, they pitched their tents on the banks of the Mouroui-Ousson (which lower down becomes the famous Blue River), and saw from their encampment "some black shapeless objects ranged in file across the stream. As they advanced nearer no change either in form or distinctness was apparent; nor was it till they were quite close that they recognized in them a troop of the wild oxen, called yak by the Tibetans. There were more than fifty of them incrusted in the ice. No doubt they had tried to swim across at the moment of congelation, and had been unable to disengage themselves. Their beautiful heads, surmounted by huge horns, were still above the surface, but their bodies were held fast in the ice, which was so transparent that the position of the imprudent beasts was easily distinguishable; they looked as if still swimming, but the eagles and ravens had pecked out their eyes."—LYELL *Principles of Geology*, bk. i, ch. 6, p. 85. (A., 1854.)

1333. FRENZY AN OUTCOME OF INFIRMITY—*Indulgence Destroys Self-control—Responsibility at Outset.*—The habit of yielding to a natural infirmity of temper often leads into paroxysms of ungovernable rage, which, in their turn, pass into a state of maniacal excitement. The poor girl who drowns herself after a quarrel with her lover, or the nurse-maid who cuts the throat of a child to whom she is tenderly attached, because her mistress has rebuked her for wearing too fine a bonnet, may be really laboring under a "temporary insanity" which drives her irresistibly to a great crime; yet, just as the man who commits a murder in a state of drunken frenzy is responsible for his irresponsibility, so is the suicide or the murderess, in so far as she has habitually neglected to control the wayward feelings whose strong excitement has impelled her to the commission of her crime.—CARPENTER *Mental Physiology*, ch. 7, p. 323. (A., 1900.)

1334. FUSION OF ROCKS—*Granite and Porphyry Cooled under Pressure—Subterranean Lakes of Melted Lava Now Existing.*—It may indeed be said that we have as yet no data for estimating the relative volume of matter simultaneously in a state of fusion at two given periods, as if we were to compare the columnar basalt of Staffa and its environs with the lava poured out in Iceland in 1783; but for this very reason it would be rash and unphilosophical to assume an excess of ancient as contrasted with modern outpourings of melted matter at particular periods of time. It would be still more presumptuous to take for granted that the more deep-seated effects of subterranean heat surpassed at remote eras the corresponding effects of internal heat in our own times. Certain porphyries and granites, and all the rocks commonly called Plutonic, are now generally supposed to have resulted from the slow cooling of materials fused and solidified under great pressure; and we cannot doubt that beneath existing volcanoes there are large spaces filled with melted stone, which must for centuries remain in an incandescent state, and then cool and become hard and crystalline when the subterranean heat shall be exhausted. That lakes of lava are continuous for hundreds of miles beneath the Chilean Andes seems established by observations made in the year 1835.—LYELL *Principles of Geology*, bk. i, ch. 11, p. 161. (A., 1854.)

1335. FUTURE MUST BE BASED UPON A PAST—*The Masses a Rising Power.*—We fail to see any scientific connection between his [Comte's] theoretical explanation of the past progress of society and his proposals for future improvement. The proposals are not, as we might expect, recommended as that towards which human society has been tending and working through the whole of history. It is thus that thinkers have usually proceeded who formed the-

ories for the future grounded on historical analysis of the past. Tocqueville, for example, and others, finding, as they thought, through all history, a steady progress in the direction of social and political equality, argued that, to smooth this transition, and make the best of what is certainly coming, is the proper employment of political foresight. We do not find M. Comte supporting his recommendations by a similar line of argument. They rest as completely, each on its separate reasons of supposed utility, as with philosophers who, like Bentham, theorize on politics without any historical basis at all. The only bridge of connection which leads from his historical speculations to his practical conclusions is the inference that, since the old powers of society, both in the region of thought and of action, are declining and destined to disappear, leaving only the two rising powers—positive thinkers on the one hand, leaders of industry on the other—the future necessarily belongs to these: spiritual power to the former, temporal to the latter. As a specimen of historical forecast this is very deficient; for are there not the masses as well as the leaders of industry? and is not theirs also a growing power?—MILL *Positive Philosophy of Auguste Comte*, p. 107. (H. H. & Co., 1887.)

1336. FUTURE OF ASTRONOMY—*All Present Knowledge But a Beginning—A Reaching-up toward God.*—Outside the solar system, the problems which demand a practical solution are all but infinite in number and extent. And these have all arisen and crowded upon our thoughts within less than a hundred years. For sidereal science became a recognized branch of astronomy only through Herschel's discovery of the revolutions of double stars in 1802. Yet already it may be and has been called "the astronomy of the future": so rapidly has the development of a keen and universal interest attended and stimulated the growth of power to investigate this sublime subject. What has been done is little—is scarcely a beginning; yet it is much in comparison with the total blank of a century past. And our knowledge will, we are easily persuaded, appear in turn the merest ignorance to those who come after us. Yet it is not to be despised, since by it we reach up groping fingers to touch the hem of the garment of the Most High.—CLERKE *History of Astronomy*, pt. ii, ch. 13, p. 528. (Bl., 1893.)

1337. FUTURE OF EARTH NOT TO BE SUNLESS—*Provision for Vast Duration of the Sun.*—We may therefore assume with great probability that the sun will still continue in its condensation, even if it only attained the density of the earth—tho it will probably become far denser in the interior owing to the enormous pressure—this would develop fresh quantities of heat, which would be sufficient to maintain for an additional 17,000,000 of years the same intensity of sunshine as that which is now the source of all terrestrial life.—HELMHOLTZ *Popular Lectures*, lect. 4, p. 182. (L. G. & Co., 1898.)

1338. FUTURE TO SURPASS PRESENT—Even in our own time we may hope to see some improvement; but the unselfish mind will find its highest gratification in the belief that, whatever may be the case with ourselves, our descendants will understand many things which are hidden from us now, will better appreciate the beautiful world in which we live, avoid much of that suffering to which we are subject, enjoy many blessings of which we are not yet worthy, and escape many of those temptations which we deplore, but cannot wholly resist.—AVEBURY *Prehistoric Times*, ch. 16, p. 577. (A., 1900.)

1339. GAMBLING, FOLLY OF—*Mathematical Calculation of Bank's Sure Winnings.*—Games which exercise either body or mind have been of high value in civilization as trainers of man's faculties. Games of pure chance played for money stand on quite a different footing; they have been from the first a delusion and a curse. In our own time there is perhaps no more pitiable sign of the slowness with which scientific ideas spread than to hear the well-dressed crowds round the gaming-table at Monaco talking about runs of luck, and fancying that it makes a difference whether one backs the black or the red. This goes on, altho schoolboys are now taught the real doctrine of chances, and how to reckon the fixed percentage of each week's stakes that will be raked in by the croupier, and not come back.—TYLOR *Anthropology*, ch. 12, p. 308. (A., 1898.)

1340. GANGES WASHING DOWN A CONTINENT—*Soil Transported by Great River—Human Building Insignificant in Comparison.*—The Rev. Mr. Everest instituted, in 1831-2, a series of observations on the earthy matter brought down by the Ganges, at Ghazepoor, 500 miles from the sea. He found that, in 1831, the number of cubic feet of water discharged by the river per second at that place was, during the

Rains (4 months)	494,208
Winter (5 months)	71,200
Hot weather (3 months)	36,330

so that we may state in round numbers that 500,000 cubic feet per second flow down during the four months of the flood season, from June to September, and less than 60,000 per second during the remaining eight months.

The average quantity of solid matter suspended in the water during the rains was, by weight, $\frac{1}{428}$th part; but as the water is about one-half the specific gravity of the dried mud, the solid matter discharged is $\frac{1}{856}$th part in bulk, or 577 cubic feet per second. This gives a total of 6,082,041,600 cubic feet for the discharge in the 122 days

of the rain. The proportion of sediment in the waters at other seasons was comparatively insignificant, the total amount during the five winter months being only 247,-881,600 cubic feet, and during the three months of hot weather 38,154,240 cubic feet. The total annual discharge, then, would be 6,368,077,440 cubic feet.

This quantity of mud would in one year raise a surface of 228½ square miles, or a square space each side of which should measure 15 miles, a height of one foot. To give some idea of the magnitude of this result, we will assume that the specific gravity of the dried mud is only one-half that of granite (it would, however, be more); in that case, the earthy matter discharged in a year would equal 3,184,038,720 cubic feet of granite. Now about 12½ cubic feet of granite weigh one ton; and it is computed that the Great Pyramid of Egypt, if it were a solid mass of granite, would weigh about 600,000,000 tons. The mass of matter, therefore, carried down annually would, according to this estimate, more than equal in weight and bulk forty-two of the great pyramids of Egypt, and that borne down in the four months of the rains would equal forty pyramids. But if, without any conjecture as to what may have been the specific gravity of the mud, we attend merely to the weight of solid matter actually proved by Mr. Everest to have been contained in the water, we find that the number of tons' weight which passed down in the 122 days of the rainy season was 339,413,760, which would give the weight of fifty-six pyramids and a half; and in the whole year 355,361,-464 tons, or nearly the weight of sixty pyramids. The base of the Great Pyramid of Egypt covers eleven acres, and its perpendicular height is about five hundred feet.—LYELL *Principles of Geology*, bk. ii, ch. 18, p. 282. (A., 1854.)

1341. ——— ——— *Work of Nature and of Man Compared.*—It is scarcely possible to present any picture to the mind which will convey an adequate conception of the mighty scale of this operation, so tranquilly and almost insensibly carried on by the Ganges, as it glides through its alluvial plain, even at a distance of 500 miles from the sea. It may, however, be stated, that if a fleet of more than eighty Indiamen, each freighted with about 1,400 tons' weight of mud, were to sail down the river every hour of every day and night for four months continuously, they would only transport from the higher country to the sea a mass of solid matter equal to that borne down by the Ganges, even in this part of its course, in the four months of the flood season. Or the exertions of a fleet of about 2,000 such ships going down daily with the same burden, and discharging it into the gulf, would be no more than equivalent to the operations of the great river.—LYELL *Principles of Geology*, bk. ii, ch. 18, p. 282. (A., 1854.)

1342. GEMS, ARTIFICIAL, INFERIOR —*Nature's Laboratories Surpass Those of Man.*—But most of the crystals of minerals which have been thus artificially formed are of minute, indeed often of microscopic, dimensions. In the underground reservoirs beneath volcanoes, however, we have all the necessary conditions for the formation of crystals of minerals on a far grander scale. High temperatures, pressures far greater than any we can command at the earth's surface, the action of superheated steam and many acid gases on the various constituents of both igneous and sedimentary rocks, and, above all, time of almost unlimited duration; these constitute such a set of conditions as may fairly be expected to result in the formation of crystals similar to those artificially produced, but of far greater size and beauty.—JUDD *Volcanoes*, ch. 5, p. 148. (A., 1899.)

1343. GENERATION, SPONTANEOUS —*Science Finds No Evidence of.*—If you ask me whether there exists the least evidence to prove that any form of life can be developed out of matter, without demonstrable antecedent life, my reply is that evidence considered perfectly conclusive by many has been adduced; and that were some of us who have pondered this question to follow a very common example, and accept testimony because it falls in with our belief, we also should eagerly close with the evidence referred to. But there is in the true man of science a desire stronger than the wish to have his beliefs upheld; namely, the desire to have them true. And this stronger wish causes him to reject the most plausible support if he has reason to suspect that it is vitiated by error. Those to whom I refer as having studied this question, believing the evidence offered in favor of "spontaneous generation" to be thus vitiated, cannot accept it. They know full well that the chemist now prepares from inorganic matter a vast array of substances which were some time ago regarded as the sole products of vitality. They are intimately acquainted with the structural power of matter, as evidenced in the phenomena of crystallization. They can justify scientifically their belief in its potency, under the proper conditions, to produce organisms. But, in reply to your question, they will frankly admit their inability to point to any satisfactory experimental proof that life can be developed save from demonstrable antecedent life.—TYNDALL *Fragments of Science (the Belfast Address)*, vol. ii, ch. 9, p. 191. (A., 1900.)

1344. ——— ——— *Theory of, Refuted* —*Biogenesis and Abiogenesis—Pasteur and Tyndall.*—Scientific men began to believe that no form of life arose *de novo (abiogenesis)*, but had its source in previous life *(biogenesis)*. It remained to Pasteur and Tyndall to demonstrate this beyond dispute and put to rout the fresh arguments for spontaneous generation which Pouchet had

advanced as late as 1859. Pasteur collected the floating dust of the air, and found by means of the microscope many organized particles, which he sowed on suitable infusions, and thus obtained rich crops of "animalculæ." He also demonstrated that these organisms existed in different degrees in different atmospheres, few in the pure air of the Mer de Glace, more in the air of the plains, most in the air of towns. He further proved that it was not necessary to insist upon hermetic sealing or cotton filters to keep these living organisms in the air from gaining access to a flask of infusion. If the neck of the flask were drawn out into a long tube and turned downwards, and then a little upwards, even tho the end be left open, no contamination gained access. Hence, if the infusion were boiled, no putrefaction would occur. The organisms which fell into the open end of the tube were arrested in the condensation water in the angle of the tube: but even if that were not so, the force of gravity acting upon them prevented them from passing up the long arm of the tube into the neck of the flask. [See PASTEUR.]—NEWMAN *Bacteria*, ch. 1, p. 4. (G. P. P., 1899.)

1345. ——— ——— *Universal Ancient Belief in—Lucretius.*—It did not enter their minds even to doubt that these low forms of life were generated in the matters in which they made their appearance. Lucretius, who had drunk deeper of the scientific spirit than any poet of ancient or modern times except Goethe, intends to speak as a philosopher, rather than as a poet, when he writes that "with good reason the earth has gotten the name of mother, since all things are produced out of the earth. And many living creatures, even now, spring out of the earth, taking form by the rains and the heat of the sun."—HUXLEY *Lay Sermons*, serm. 15, p. 346. (A., 1895.)

1346. GENIUS ACCOMPANIED BY TIRELESS INDUSTRY—*Herschel Making His Own Reflectors—Undaunted by Many Failures—A Sister's Devotion.*—Having purchased the apparatus of a Quaker optician, he [Herschel] set about the manufacture of specula with a zeal which seemed to anticipate the wonders they were to disclose to him. It was not until fifteen years later that his grinding and polishing machines were invented, so the work had at that time to be entirely done by hand. During this tedious and laborious process (which could not be interrupted without injury, and lasted on one occasion sixteen hours), his strength was supported by morsels of food put into his mouth by his sister, and his mind amused by her reading aloud to him the "Arabian Nights," "Don Quixote," or other light works. At length, after repeated failures, he found himself provided with a reflecting telescope—a 5½-foot Gregorian—of his own construction. A copy of his first observation with it on the great nebula in Orion—an object of continual amazement and assiduous inquiry to him—is preserved by the Royal Society. It bears the date March 4, 1774.—CLERKE *History of Astronomy*, ch. 1, p. 14. (Bl., 1893.)

1347. GENIUS DEVELOPED BY LABOR—*Studious Industry of Mozart.*—That, notwithstanding the exuberance of his own creative power, Mozart constantly disciplined it by the most sedulous study, and that he could, without being chargeable with imitation, assimilate (so to speak) into his own musical constitution all that he found suitable in the works of others as pabulum for his genius, is one of its most remarkable features. "It is a very great error," he wrote to a friend, "to suppose that my art has become so exceedingly easy to me. I assure you there is scarcely any one who has worked at the study of composition as I have. You could hardly mention any famous composer whose writings I have not diligently and repeatedly studied throughout." And, in this self-education, as Mr. Holmes remarks, "whatever of striking, new, or beautiful he met with in the works of others, left its impression on him; and he often reproduced these effects, not servilely, but mingling his own nature and feeling with them, in a manner not less surprising than delightful."—CARPENTER *Mental Physiology*, ch. 6, p. 274. (A., 1900.)

1348. GENIUS, INSPIRATION OF—*How Mozart Composed.*—We shall now endeavor to trace out the manner in which he [Mozart] worked; and of this we fortunately have a pretty full account from himself in a letter to a friend:

"You say you should like to know my way of composing, and what method I follow in writing works of some extent. I can really say no more on the subject than the following, for I myself know no more about it, and cannot account for it. When I am, as it were, completely myself, entirely alone, and of good cheer, say, traveling in a carriage, or walking after a good meal, or during the night when I cannot sleep; it is on such occasions that my ideas flow best and most abundantly. Whence and how they come I know not, nor can I force them. Those ideas that please me I retain in my memory, and am accustomed (as I have been told) to hum them to myself. If I continue in this way, it soon occurs to me how I may turn this or that *morceau* to account, so as to make a good dish of it, that is to say, agreeably to the rules of counterpoint, to the peculiarities of the various instruments, etc.

"All this fires my soul, and, provided I am not disturbed, my subject enlarges itself, becomes methodized and defined, and the whole, tho it be long, stands almost complete and finished in my mind, so that I can survey it like a fine picture, or a beautiful statue, at a glance. Nor do I hear in my imagination the parts successively, but I

hear them, as it were, all at once *(gleich alles zusammen)*. What a delight this is I cannot tell! All this inventing, this pondering, takes place in a pleasing lively dream. Still the actual hearing of the *tout ensemble* is after all the best. What has been thus produced I do not easily forget, and this is perhaps the best gift I have my Divine Maker to thank for.

"When I proceed to write down my ideas I take out of the bag of my memory, if I may use that phrase, what has previously been collected into it in the way I have mentioned. For this reason, the committing to paper is done easily enough; for everything is, as I said before, already finished; and it rarely differs on paper from what it was in my imagination."—HOLMES *Life of Mozart*, quoted by CARPENTER in *Mental Physiology*, ch. 6, p. 272. (A., 1900.)

1349. GENIUS OF DISCOVERY—*Aristotle's Absurd Physics and Immortal Logic.*—The genius of discovery depends altogether on the number of these random notions and guesses which visit the investigator's mind. To be fertile in hypotheses is the first requisite, and to be willing to throw them away the moment experience contradicts them is the next . . . The important thing to notice is that the good flashes and the bad flashes, the triumphant hypotheses and the absurd conceits, are on an exact equality in respect of their origin. Aristotle's absurd physics and his immortal logic flow from one source: the forces that produce the one produce the other.—JAMES *Essays in Popular Philosophy*, p. 249. (L. G. & Co., 1899.)

1350. GENIUS OF PRIMITIVE MECHANICS—*Wonderful Results with Meager Resources.*—The first of them [mechanics] had a poorly furnished workshop. "His body," as Emerson says, "was a whole chest of tools." But he had not the knack of using them. He was naked and houseless. His needs, out of which all arts in all ages spring, were few. His mission was to subdue the earth and to redeem it. Compared with his progeny of our day, he would seem an object of pity. But his brain was superabundant. His soul was full of capacities. He was the father of us all.—MASON *Aboriginal American Mechanics* in *Memoirs of Int. Congress of Anthropology*, p. 69. (Sch. P. C.)

1351. GENIUS QUENCHED—*Crushing Power of Hostile Criticism—Great Discoverer Ridiculed.*—It is quite true, as Helmholtz says, that Young was in advance of his age; but something is to be added which illustrates the responsibility of our public writers. For twenty years this man of genius was quenched—hidden from the appreciative intellect of his countrymen—deemed in fact a dreamer, through the vigorous sarcasm of a writer who had then possession of the public ear, and who in the *Edinburgh Review* poured ridicule upon Young and his speculations. To the celebrated Frenchmen Fresnel and Arago he was first indebted for the restitution of his rights; for they, especially Fresnel, remade independently, as Helmholtz says, and vastly extended his discoveries. To the students of his works Young has long since appeared in his true light, but these twenty blank years pushed him from the public mind, which became in turn filled with the fame of Young's colleague at the Royal Institution, Davy, and afterwards with the fame of Faraday. Carlyle refers to a remark of Novalis, that a man's self-trust is enormously increased the moment he finds that others believe in him. If the opposite remark be true—if it be a fact that public disbelief weakens a man's force—there is no calculating the amount of damage these twenty years of neglect may have done to Young's productiveness as an investigator. It remains to be stated that his assailant was Mr. Henry Brougham, afterwards Lord Chancellor of England.—TYNDALL *Lectures on Light*, lect. 2, p. 51. (A., 1898.)

1352. GENIUS SEES ABSTRACT TRUTH—*Phenomena Moved by an Unseen Something behind Them.*—The human mind, in the exercise of its own faculties and powers, sometimes by careful reasoning, sometimes by the intuitions of genius unconscious of any process, is able, from time to time, to reach now one, now another, of those purely intellectual conceptions which are the basis of all that is intelligible to us in the order of the material world. We look for an ideal order or simplicity in material law; and the very possibility of exact science depends upon the fact that such ideal order does actually prevail, and is related to the abstract conceptions of our own intellectual nature. It is in this way that many of the greatest discoveries of science have been made. Especially have the great pioneers in new paths of discovery been led to the opening of those paths by that fine sense for abstract truths which is the noblest gift of genius. Copernicus, Kepler, and Galileo were all guided in their profound interpretations of visible phenomena by those intuitions which arise in minds finely organized, brought into close relations with the mind of nature, and highly trained in the exercise of speculative thought. They guessed the truth before they proved it to be true; and those guesses had their origin in abstract ideas of the mind, which turned out to be ideas really embodied in the order of the universe. So constantly has this recurred in the history of science that, as Dr. Whewell ["History of the Inductive Sciences," 2d edition, vol. i, p. 434] says, it is not to be considered as an exception, but as the rule.—ARGYLL *Reign of Law*, ch. 2, p. 66. (Burt.)

1353. GENIUS UNFAVORABLE TO VOLUNTARY ATTENTION—*Holding Attention upon One Subject Gives Mastery.*—It is probable that genius tends actually to pre-

vent a man from acquiring habits of voluntary attention, and that moderate intellectual endowments are the soil in which we may best expect, here as elsewhere, the virtues of the will, strictly so called, to thrive. But, whether the attention come by grace of genius or by dint of will, the longer one does attend to a topic the more mastery of it one has. And the faculty of voluntarily bringing back a wandering attention, over and over again, is the very root of judgment, character, and will. No one is *compos sui* if he have it not.—JAMES *Psychology*, vol. i, ch. 11, p. 424. (H. H. & Co., 1899.)

1354. GEOGRAPHY AND ETHNOLOGY, MEDIEVAL—*Travelers of Middle Ages—Their Works Dramatic—The Public Ignorant and Credulous.*—The earlier travelers of the Middle Ages, as for instance John Mandèville (1353), Hans Schiltberger of Munich (1425), and Bernhard von Breytenback (1486), delight us even in the present day by their charming simplicity, their freedom of style, and the self-confidence with which they step before a public, who, from their utter ignorance, listen with the greater curiosity and readiness of belief, because they have not as yet learned to feel ashamed of appearing ignorant, amused, or astonished. The interest attached to the narratives of travels was then almost wholly dramatic, and the necessary and easily introduced admixture of the marvelous gave them almost an epic coloring. The manners of foreign nations are not so much described as they are rendered incidentally discernible by the contact of the travelers with the natives. The vegetation is unnamed and unheeded, with the exception of an occasional allusion to some pleasantly flavored or strangely formed fruit, or to the extraordinary dimensions of particular kinds of stems or leaves of plants. Among animals, they describe, with the greatest predilection, first, those which exhibit most resemblance to the human form, and next, those which are the wildest and most formidable. The contemporaries of these travelers believed in all the dangers which few of them had shared, and the slowness of navigation and the want of means of communication caused the Indies, as all the tropical regions were then called, to appear at an immeasurable distance. Columbus was not yet justified in writing to Queen Isabella, "the world is small, much smaller than people suppose."—HUMBOLDT *Cosmos*, vol. ii, pt. i, p. 78. (H., 1897.)

1355. GEOLOGY AND HISTORY, ANALOGY OF—*The Present in the Past.*—By these researches into the state of the earth and its inhabitants at former periods, we acquire a more perfect knowledge of its present condition, and more comprehensive views concerning the laws now governing its animate and inanimate productions. When we study history, we obtain a more profound insight into human nature, by instituting a comparison between the present and former states of society. We trace the long series of events which have gradually led to the actual posture of affairs; and by connecting effects with their causes, we are enabled to classify and retain in the memory a multitude of complicated relations—the various peculiarities of national character—the different degrees of moral and intellectual refinement, and numerous other circumstances, which, without historical associations, would be uninteresting or imperfectly understood. As the present condition of nations is the result of many antecedent changes, some extremely remote and others recent, some gradual, others sudden and violent; so the state of the natural world is the result of a long succession of events; and if we would enlarge our experience of the present economy of Nature, we must investigate the effects of her operations in former epochs.—LYELL *Principles of Geology*, bk. i, ch. 1, p. 1. (A., 1854.)

1356. ——— ——— *Relative Utility Yet To Be Proved.*—The discovery of other systems in the boundless regions of space was the triumph of astronomy; to trace the same system through various transformations—to behold it at successive eras adorned with different hills and valleys, lakes and seas, and peopled with new inhabitants, was the delightful meed of geological research. By the geometer were measured the regions of space and the relative distances of the heavenly bodies; by the geologist myriads of ages were reckoned, not by arithmetical computation, but by a train of physical events—a succession of phenomena in the animate and inanimate worlds—signs which convey to our minds more definite ideas than figures can do of the immensity of time.

Whether our investigation of the earth's history and structure will eventually be productive of as great practical benefits to mankind as a knowledge of the distant heavens, must remain for the decision of posterity. It was not till astronomy had been enriched by the observations of many centuries, and had made its way against popular prejudices to the establishment of a sound theory, that its application to the useful arts was most conspicuous. The cultivation of geology began at a later period; and in every step which it has hitherto made towards sound theoretical principles it had to contend against more violent prepossessions. The practical advantages already derived from it have not been inconsiderable; but our generalizations are yet imperfect, and they who come after us may be expected to reap the most valuable fruits of our labor. Meanwhile, the charm of first discovery is our own; and, as we explore this magnificent field of inquiry, the sentiment of a great historian of our times may continually be present to our minds, that "he who calls what has vanished back again into

being enjoys a bliss like that of creating" (Niebuhr, "History of Rome," vol. i, p. 5). —LYELL *Principles of Geology*, bk. i, ch. 4, p. 61. (A., 1854.)

1357. GEOLOGY HAS INDUSTRIAL VALUE—*Money Wasted in Vain Search for Coal—Knowledge of Formations Would Save Outlay.*—"Whatever withdraws us from the power of the senses," says the moralist [Johnson], "whatever makes the past, the distant, or the future predominate over the present, advances us in the dignity of thinking beings." And geology, in a peculiar manner, supplies to the intellect an exercise of this ennobling character. But it has, also, its cash value. The time and money squandered in Great Britain alone in searching for coal in districts where the well-informed geologist could have at once pronounced the search hopeless, would much more than cover the expense at which geological research has been prosecuted throughout the world.—MILLER *Old Red Sandstone*, ch. 10, p. 177. (G. & L., 1851.)

1358. GEOLOGY, ONCE A SYSTEM OF CATASTROPHES—*Now Accords with the Harmony of Nature—Theology Seeks the Same Harmony.*—A century ago there was none [geology]. Science went out to look for it, and brought back a geology which, if Nature were a harmony, had falsehood written almost on its face. It was the Geology of Catastrophism—a geology so out of line with Nature, as revealed by the other sciences, that on a priori grounds a thoughtful mind might have been justified in dismissing it as a final form of any science. And its fallacy was soon and thoroughly exposed. The advent of modified uniformitarian principles all but banished the word "catastrophe" from science, and marked the birth of geology as we know it now. Geology, that is to say, had fallen at last into the great scheme of law. Religious doctrines, many of them at least, have been up to this time all but as catastrophic as the old geology. They are not on the lines of Nature as we have learned to decipher her. If any one feels, as science complains that it feels, that the lie of things in the spiritual world as arranged by theology is not in harmony with the world around, is not, in short, scientific, he is entitled to raise the question whether this be really the final form of those departments of theology to which his complaint refers. He is justified, moreover, in demanding a new investigation with all modern methods and resources; and science is bound by its principles, not less than by the lessons of its own past, to suspend judgment till the last attempt is made. —DRUMMOND *Natural Law in the Spiritual World*, int., p. 17. (H. Al.)

1359. GEOLOGY, ORIGIN OF—*Ancient Egyptians—Herodotus Knew that Egypt Had Been Once Submerged.*—We know that the Egyptian priests were aware, not only that the soil beneath the plains of the Nile, but that also the hills bounding the great valley, contained marine shells; and Herodotus inferred from these facts that all lower Egypt, and even the highlands above Memphis, had once been covered by the sea ["Euterpe," 12]. As similar fossil remains occur in all parts of Asia hitherto explored, far in the interior of the continent as well as near the sea, they could hardly have escaped detection by some Eastern sages not less capable than the Greek historian of reasoning philosophically on natural phenomena.—LYELL *Principles of Geology*, bk. i, ch. 2, p. 6. (A., 1854.)

1360. GEOLOGY TESTIFIES TO A BEGINNING—The chain of life in geological time presents a wonderful testimony to the reality of a beginning. Just as we know that any individual animal must have had its birth, its infancy, its maturity, and will reach an end of life, so we trace species and groups of species to their beginning, watch their culmination, and perhaps follow them to their extinction. . . . But its revelation of the fact that nearly all the animals and plants of the present day had a very recent beginning in geological time, and its disclosure of the disappearance of one form of life after another as we go back in time, till we reach the comparatively few forms of life of the Lower Cambrian, and finally have to rest over the solitary grandeur of *Eozoon*, oblige it to say that nothing known to it is self-existent and eternal.—DAWSON *Facts and Fancies in Modern Science*, lect. 3, p. 118. (A. B. P. S.)

1361. GEOMETRY A GROWTH FROM BUILDER'S ARTS—*The Straight Line Is the Stretched Line.*—It must be clearly understood that elementary geometry was not actually invented by means of definitions, axioms, and demonstrations like Euclid's. Its beginnings really arose out of the daily practical work of land-measurers, masons, carpenters, tailors. This may be seen in the geometrical rules of the altar-builders of ancient India, which do not tell the bricklayer to draw a plan of such and such lines, but to set up poles at certain distances, and stretch cords between them. It is instructive to see that our term *straight line* still shows traces of such an early practical meaning: *line* is *linen* thread, and *straight* is the participle of the old verb *to stretch*. If we stretch a thread tight between two pegs, we see that the stretched thread must be the shortest possible; which suggests how the straight line came to be defined as the shortest distance between two points. Also, every carpenter knows the nature of a right angle, and he is accustomed to parallel lines, or such as keep the same distance from one another.—TYLOR *Anthropology*, ch. 13, p. 319. (A., 1899.)

1362. GERM A SEED—*Each Propagates Only Its Kind.*—From their respective viruses you may plant typhoid fever, scarlatina, or smallpox. What is the crop

that arises from this husbandry? As surely as a thistle rises from a thistle seed, as surely as the fig comes from the fig, the grape from the grape, the thorn from the thorn, so surely does the typhoid virus increase and multiply into typhoid fever, the scarlatina virus into scarlatina, the smallpox virus into smallpox. What is the conclusion that suggests itself here? It is this: That the thing which we vaguely call a virus is to all intents and purposes a seed. Excluding the notion of vitality, in the whole range of chemical science you cannot point to an action which illustrates this perfect parallelism with the phenomena of life—this demonstrated power of self-multiplication and reproduction. The germ theory alone accounts for the phenomena.—TYNDALL *Floating Matter of the Air,* essay 1, p. 41. (A., 1895.)

1363. GERM-DESTROYERS—*White Corpuscles or Leucocytes—The Wise Providence of the Creator—High Purpose Found for Supposedly Useless Organ.*—Quite recently it has been proved that the white corpuscles of the blood, whose function was previously unknown, are really independent living organisms. They are produced in large numbers by the spleen, an organ which has long been a puzzle to physiologists, but whose function and importance to the organism seem to be now made clear. They are much smaller and less numerous than the red blood-globules; they move about quite independently; and they behave in a manner which shows that they are closely allied to, if not identical with, the amebæ found abundantly in stagnant water, and which form such interesting microscopic objects. These minute animal organisms, which inhabit not only our blood-vessels, but all the tissues of the body, have an important function to perform on which our very lives depend. This function is, to devour and destroy the bacteria or germs of disease which may gain an entrance to our blood or tissues, and which, when their increase is unchecked, produce various disorders and even death. Under the higher powers of the microscope the leucocytes, as they are termed, can be observed continually moving about, and on coming in contact with any of these bacteria or their germs, or other hurtful substances, they send out pseudopodia from their protoplasm which envelops the germ and soon causes it to disappear: but they also appear sometimes to produce a secretion which is injurious to the bacteria, and so destroys them, and these may perhaps be distinct organisms.—WALLACE *The Wonderful Century,* ch. 14, p. 145. (D. M. & Co., 1899.)

1364. GERM-THEORY — *Micro-organisms in the Air—Treatment of Wounds.*—Schwann was one of the first to point out that when a decoction of meat is effectually screened from the air, or supplied solely with calcined air, putrefaction does not set in. Helmholtz and Pasteur confirmed this, but it may be said with some truth that Schwann originated the germ-theory, and Lister applied it in the treatment of wounds. Lister believed that if he could surround wounds with filtered air the results would be as good as if they were shut off from the air altogether.—NEWMAN *Bacteria,* ch. 3, p. 101. (G. P. P., 1899.)

1365. GERM, WONDERFUL DEVELOPMENT OF—*The Unseen Artist.*—"Strange possibilities," he [Huxley] says, "lie dormant in that semifluid globule. Let a moderate supply of warmth reach its watery cradle and the plastic matter undergoes changes so rapid and yet so steady and purpose-like in their succession that one can only compare them to those operated by a skilled modeler upon a formless lump of clay. As with an invisible trowel the mass is divided and subdivided into smaller and smaller portions, until it is reduced to an aggregation of granules not too large to build withal the finest fabrics of the nascent organism. And then it is as if a delicate finger traced out the line to be occupied by the spinal column, and molded the contour of the body; pinching up the head at one end, the tail at the other, and fashioning flank and limb into due proportions in so artistic a way that, after watching the process hour by hour, one is almost involuntarily possessed by the notion that some more subtle aid to vision than an achromatic would show the hidden artist, with his plan before him, striving with skilful manipulation to perfect his work."—DRUMMOND *Natural Law in the Spiritual World,* essay 8, p. 260. (H. Al.)

1366. GERMS DESTROYED BY DISCONTINUOUS BOILING—*Softening Period Seized for Each Kind—Theory Proved by Experiment—The Test of Prevision.*—An infusion infected with the most powerfully resistant germs, but otherwise protected against the floating matters of the air, is gradually raised to its boiling-point. Such germs as have reached the soft and plastic state immediately preceding their development into bacteria are thus destroyed. The infusion is then put aside in a warm room for ten or twelve hours. If for twenty-four, we might have the liquid charged with well-developed bacteria. To anticipate this, at the end of ten or twelve hours we raise the infusion a second time to the boiling-temperature, which, as before, destroys all germs then approaching their point of final development. The infusion is again put aside for ten or twelve hours, and the process of heating is repeated. We thus kill the germs *in the order of their resistance,* and finally kill the last of them. No infusion can withstand this process if it be repeated a sufficient number of times. Artichoke, cucumber, and turnip infusions, which had proved specially obstinate when infected with the germs of desiccated hay were com-

pletely broken down by this method of discontinuous heating, three minutes being found sufficient to accomplish what three hundred minutes' continuous boiling failed to accomplish. I applied the method, moreover, to infusions of various kinds of hay, including those most tenacious of life. Not one of them bore the ordeal. These results were clearly foreseen before they were realized, so that the germ-theory fulfils the test of every true theory, that test being the power of prevision.—TYNDALL *Fragments of Science*, vol. ii, ch. 13, p. 321. (A., 1900.)

1367. GERMS EVADE EXPERIMENTERS—*Unharmed by Supposed Fatal Processes—Possibility of Exclusion.*—Germs will pass unwetted and unscathed through sulfuric acid unless the most special care is taken to detain them. . . . The air passes in bubbles through the bulbs; and to make the method [of purifying air by passing it through sulfuric acid] secure, the passage of the air must be so slow as to cause the whole of its floating matter, even to the very core of each bubble, to touch the surrounding liquid. But if this precaution be observed, water will be found quite as effectual as sulfuric acid. By the aid of an air-pump, in a highly infective atmosphere I have thus drawn air for weeks without intermission, first through bulbs containing water, and afterwards through vessels containing organic infusions, without any appearance of life. The germs were not killed by the water, but they were effectually intercepted, while the objection that the air had been injured by being brought into contact with strongly corrosive substances was annulled.—TYNDALL *Floating Matter of the Air*, essay 5, p. 281. (A., 1895.)

1368. GERMS INDISTINGUISHABLE—*Structural Differences Notwithstanding—Oak — Palm — Lichen.* — If a botanist be asked the difference between an oak, a palm-tree, and a lichen, he will declare that they are separated from one another by the broadest line known to classification. Without taking into account the outward differences of size and form, the variety of flower and fruit, the peculiarities of leaf and branch, he sees even in their general architecture types of structure as distinct as Norman, Gothic, and Egyptian. But if the first young germs of these three plants are placed before him and he is called upon to define the difference, he finds it impossible. He cannot even say which is which. Examined under the highest powers of the microscope, they yield no clue. Analyzed by the chemist with all the appliances of his laboratory, they keep their secret.—DRUMMOND *Natural Law in the Spiritual World*, essay 8, p. 257. (H. Al.)

1369. ——— ——— *Uniformity, Apparent, of All in Earliest Stage—Gradual Differentiation through Class, Order, Family, Genus, Species—Individual Repeating History of Race.*—All animals start together as a single cell, so that man cannot be distinguished from the lobster or mollusk. An embryo arises from this cell, which shows itself to be a vertebrate in distinction from an invertebrate, but is as yet not a mammal, but more like a fish. With further development it shows a slight approximation toward the reptiles, but, instead of becoming a member of this class, takes a different course, and declares itself to be a mammal. Next, it turns toward the direction of the primates rather than rodents or ungulates; then it exhibits the characteristics of an ape, in distinction from the lemurs; and finally, just before birth, it takes on the features of man. And this story is repeated in all cases, the line of development being the sub-kingdom, the class, the subclass, the order, the family, the genus, the species—thus coinciding with one treelike classification of animals.—CONN *Evolution of To-day*, ch. 4, p. 148. (G. P. P., 1886.)

1370. ——— ——— *Vegetable and Animal—Worm and Man.*—Compare next the two sets of germs, the vegetable and the animal. And there is still no shade of difference. Oak and palm, worm and man, all start life together. No matter into what strangely different forms they may afterwards develop, no matter whether they are to live on sea or land, creep or fly, swim or walk, think or vegetate, in the embryo as it first meets the eye of science they are indistinguishable. The apple which fell in Newton's garden, Newton's dog Diamond, and Newton himself began life at the same point.—DRUMMOND *Natural Law in the Spiritual World*, essay 8, p. 258. (H. Al.)

1371. GERMS INNUMERABLE—*The Air Thick with Microscopic Life.*—It has been a common objection of abiogenists that, if the doctrine of biogeny is true, the air must be thick with germs; and they regard this as the height of absurdity. But Nature occasionally is exceedingly unreasonable, and Professor Tyndall has proved that this particular absurdity may nevertheless be a reality. He has demonstrated that ordinary air is no better than a sort of stirabout of excessively minute solid particles; that these particles are almost wholly destructible by heat, and that they are strained off, and the air rendered optically pure, by being passed through cotton-wool.—HUXLEY *Lay Sermons*, serm. 15, p. 360. (A., 1895.)

1372. GERMS, SIZE OF, BAFFLES DESCRIPTION—*Infinitesimal Minuteness with Power To Accomplish Vast Results.*—Questions of size are always difficult to settle or determine from a popular point of view, and, when we seek to gain some adequate idea of the dimensions of germs, we are met with the difficulty of translating into terms of common life those of the infinitely little. If we speak of a germ which in length is the one-ten-thousandth part of an inch—that is, equals one part of an inch which has been

divided, as to its length, into ten thousand parts—we utterly fail to grasp any notion of the size indicated. An appeal to figurative description, while more graphic in character perchance, yet leaves us with the dimmest conceptions of the dimensions of germs.

One writer tells us that on the area of a single square inch we could place, in a single layer, a population of common germs or bacteria one hundred times as great as the population of London. Graphic as is this estimate, the idea of the actual size of the individual germs remains simply unattainable. It is this diminutive size compared with the great results in the way of disease certain of these germs may and do produce, which is more than sufficient to appal us.—WILSON *Glimpses of Nature*, ch. 26, p. 84. (Hum., 1892.)

1373. GIANTS AMONG THE SUNS—*Alpha Centauri—Sirius Equals Two Thousand Suns Like Ours in Size.*—We have seen, however, that Alpha Centauri gives out about three times as much light as our sun. It follows that Sirius shines in reality three hundred times more brightly than the sun. Now, this implies that if the surface of Sirius is of the same intrinsic brightness as the sun's—that is, if on the average each square mile of the surface of Sirius gives out the same quantity of light as each square mile of the sun's surface—then the surface of Sirius must be 300 times as large as the sun's. It would follow that the diameter of Sirius is between 17 and 18 times as large as the sun's. (For 17 times 17 are less than 300, and 18 times 18 are greater than 300.) Hence the volume of Sirius would be about 2,200 times as great as the sun's (this number 2,200 being obtained by multiplying 300 by 17⅓, which is nearly equivalent to multiplying 17⅓, twice into itself). This is on the supposition of equal surface-luster; and it cannot be regarded as certain that Sirius is not considerably brighter than our sun as respects his actual surface. Of course if this is the case we cannot assume that Sirius is larger in so great a proportion as when we suppose his intrinsic luster the same as the sun's.

But it is worthy of notice that the eminent French physicist Ste.-Claire-Deville considers it impossible that under any circumstances a surface can be much hotter or more luminous than the solar surface. We shall probably be within the limits of fact if we regard the surface of Sirius as not more than twice as bright as the sun's. This would leave his surface 150 times larger than the sun's, or, for convenience of reckoning, say 144 times; his diameter would thus be twelve times the sun's, and his volume 1,728 times the sun's.

Have I not rightly called Sirius a "king of suns"? From that glorious orb, nearly 2,000 such orbs as the sun, that great and mighty globe, instinct with fire and life, might be formed, each fit to be the center of a scheme of circling worlds as important as that over which our sun bears sway!—PROCTOR *Expanse of Heaven*, pp. 243-245. (L. G. & Co., 1897.)

1374. GIANTS OF PRIMEVAL DAYS—*The Old Man of Cromagnon.*—The reader, reflecting on what he has learned from history may be disposed here to ask: "Must we suppose Adam to have been one of these Turanian men, like 'the old man of Cromagnon'"? In answer, I would say that there is no good reason to regard the first man as having resembled a Greek Apollo or an Adonis. He was probably of sterner and more muscular mold. But the gigantic paleolithic men of the European caves are more probably representatives of that fearful and powerful race who filled the antediluvian world with violence, and who reappear in postdiluvian times as the Anakim and traditional giants, who constitute a feature in the early history of so many countries. Perhaps nothing is more curious in the revelations as to the most ancient cavemen than that they confirm the old belief that there were "giants in those days."—DAWSON *Facts and Fancies in Modern Science*, lect. 4, p. 169. (A. B. P. S.)

1375. GIANTS OF THE VEGETABLE KINGDOM—*Plants and Flowers of the Tropics.*—In the tropics, plants are more succulent, of a fresher green, and have larger and more glossy leaves, than in the northern regions. Social plants, which give such a character of uniformity to European vegetation, are almost wholly absent in the equatorial zone. Trees, almost twice as high as our oaks, there bloom with flowers as large and splendid as our lilies. On the shady banks of the Magdalena River, in South America, grows a climbing *Aristolochia*, whose blossoms, measuring four feet in circumference, the Indian children sportively draw on their heads as caps. In the South Indian Archipelago, the flower of the *Rafflesia* is nearly three feet in diameter, and weighs above fourteen pounds.—HUMBOLDT *Views of Nature*, p. 230. (Bell, 1896.)

1376. GIBRALTAR, STRAITS OF—*Current Flowing from Atlantic into Mediterranean—Supply without Return—A Problem in Nature.*—It is well known that a powerful current sets constantly from the Atlantic into the Mediterranean, and its influence extends along the whole southern borders of that sea, and even to the shores of Asia Minor. Captain Smyth found, during his survey, that the central current ran constantly at the rate of from three to six miles an hour eastward into the Mediterranean, the body of water being three miles and a half wide. But there are also two lateral currents—one on the European and one on the African side, each of them about two miles and a half broad, and flowing at about the same rate as the central stream. These lateral currents ebb and flow with the tide, setting alternately into the Mediterranean and into the Atlantic. The excess

of water constantly flowing in is very great, and there is only one cause to which this can be attributed, the loss of water in the Mediterranean by evaporation. That the level of this sea should be considerably depressed by this cause is quite conceivable, since we know that the winds blowing from the shores of Africa are hot and dry; and hygrometric experiments recently made in Malta and other places show that the mean quantity of moisture in the air investing the Mediterranean is equal only to one-half of that in the atmosphere of England. The temperature also of the great inland sea is upon an average higher, by 3½° of Fahrenheit, than the eastern part of the Atlantic Ocean in the same latitude, which must greatly promote its evaporation. The Black Sea being situated in a higher latitude, and being the receptable of rivers flowing from the north, is much colder, and its expenditure far less; accordingly it does not draw any supply from the Mediterranean, but, on the contrary, contributes to it by a current flowing outwards, for the most part of the year, through the Dardanelles. The discharge, however, at the Bosporus is so small, when compared to the volume of water carried in by rivers, as to imply a great amount of evaporation in the Black Sea.—LYELL *Principles of Geology,* bk. ii, ch. 20, p. 333. (A., 1854.)

1377. GLACIER CHANGING SHAPE— *Fracture and Regelation.*—All the phenomena of motion, on which the idea of viscosity [a view still held by eminent observers, as at least a partial explanation of glacial phenomena—see Russell, "Glaciers of North America"] has been based, are brought by such experiments as the above [of breaking and freezing together the fragments of ice] into harmony with the demonstrable properties of ice. In virtue of this property, the glacier accommodates itself to its bed while preserving its general continuity, crevasses are closed up, and the broken ice of a cascade, such as that of the Talèfre or the Rhone, is recompacted to a solid continuous mass.—TYNDALL *Hours of Exercise in the Alps (Notes on Ice and Glaciers),* ch. 1, p. 355. (A., 1898.)

1378. GLACIER, DISTINCTIVE CARVING OF—*Markings Could Not Be the Work of Floating Ice.*—In the State of Maine I have followed, compass in hand, the same set of furrows, running from north to south in one unvarying line, over a surface of one hundred and thirty miles, from the Katahdin Iron Range to the seashore. These furrows follow all the inequalities of the country, ascending ranges of hills varying from twelve to fifteen hundred feet in height, and descending into the intervening valleys only two or three hundred feet above the sea, or sometimes even on a level with it. I take it to be impossible that a floating mass of ice should travel onward in one rectilinear direction, turning neither to the right nor to the left, for such a distance. Equally impossible would it be for a detached mass of ice, swimming on the surface of the water, or even with its base sunk considerably below it, to furrow in a straight line the summits and sides of the hills, and the bottoms of the intervening valleys. It would be carried over the inequalities of the country without touching the lowest depressions.—AGASSIZ *Journey in Brazil,* ch. 13, p. 402. (H. M. & Co., 1896.)

1379. GLACIER OF CONTINENTAL MAGNITUDE—*Greenland a Type of Ancient North America.*—The vast ice-sheet covering nearly all of Greenland is of the continental type, and, as is well known, is the largest existing ice-body in the northern hemisphere. Its extension northward has not been fully determined, but as nearly as can be judged it terminates in about latitude 82°. Its area is in the neighborhood of 600,000 square miles. If transferred bodily to the eastern portion of the United States, it would extend from northern Maine to Georgia, and cover a belt of country 500 miles broad. Vast as this ice-sheet is known to be, it takes what may be said to be second or third rank when contrasted with the continental glaciers that occupied Canada and a large portion of the United States in Pleistocene times. The exploration of existing glaciers derives one of its principal attractions from the fact that such studies assist in interpreting the records left by ancient glaciers in various parts of the world. This in turn brings one to the consideration of the still broader problems of the cause of climatic changes which favored the growth of vast Pleistocene glaciers in regions now enjoying a temperate climate, and inhabited by the most civilized people of the earth.—RUSSELL *Glaciers of North America,* ch. 2, p. 35. (G. & Co., 1897.)

1380. GLACIERS, FORMING AND MOVEMENT OF — *Rivers Flowing Under Arches of Ice.*—In the temperate zone the snow lies for months in winter on the summit of every high mountain, while in the arctic regions a long summer's day of half a year's duration is insufficient to melt the snow, even on land just raised above the level of the sea. It is therefore not surprising, since the atmosphere becomes colder in proportion as we ascend in it, that there should be heights, even in tropical countries, where the snow never melts. The lowest limit to which the perpetual snow extends downwards from the tops of mountains at the equator is an elevation of not less than 16,000 feet above the sea; while in the Swiss Alps, in lat. 46° N., it reaches as low as 8,500 feet above the same level, the loftier peaks of the Alpine chain being from 12,000 to 15,000 feet high. The frozen mass augmenting from year to year would add indefinitely to the altitude of Alpine summits were it not relieved by its descent through

the larger and deeper valleys to regions far below the general snow-line. To these it slowly finds its way in the form of rivers of ice, called glaciers, the consolidation of which is produced by pressure and by the congelation of water infiltered into the porous mass, which is always undergoing partial liquefaction, and receiving in summer occasional showers of rain on its surface. In a day of hot sunshine or mild rain, innumerable rills of pure and sparkling water run in icy channels along the surface of the glaciers, which in the night shrink and come to nothing. They are often precipitated in bold cascades into deep fissures in the ice, and contribute together with springs to form torrents, which flow in tunnels at the bottom of the glaciers for many a league, and at length issue at their extremities from beneath beautiful caverns or arches. The waters of these streams are always densely charged with the finest mud, produced by the grinding of rock and sand under the weight of the moving mass.—LYELL *Principles of Geology*, bk. ii, ch. 15, p. 222. (A., 1854.)

1381. GLACIERS NOW IN ACTION—*Present Agree with Ancient Results—Continuity of Nature.*—Certainly, no one familiar with the facts could suppose that floating ice or icebergs had abraded, polished, and furrowed the bottom of narrow valleys as we find them worn, polished, and grooved by glaciers. And it must be remembered that this is a theory founded not upon hypothesis, but upon the closest comparison. I have not become acquainted with these marks in regions where glaciers no longer exist, and made a theory to explain their presence. I have, on the contrary, studied them where they are in process of formation. I have seen the glacier engrave its lines, plow its grooves and furrows in the solid rock, and polish the surfaces over which it moved, and was familiar with all this when I found afterwards appearances corresponding exactly to those which I had investigated in the home of the present glaciers. I could therefore say, and I think with some reason, that "this also is the work of the glacier acting in ancient times as it now acts in Switzerland."—AGASSIZ *Geological Sketches*, ser. ii, p. 39. (H. M. & Co., 1896.)

1382. GLASS-MAKING IN NATURE'S LABORATORIES—But when the lava contains no ready-formed crystals, but consists entirely of a glassy substance in a more or less perfect state of fusion, the liberation of steam gives rise to the formation of the beautiful material known as "pumice." Pumice consists of a mass of minute glass bubbles; these bubbles have not usually, however, retained their globular form, but have been elongated in one direction through the movement of the mass while it was still in a plastic state.—JUDD *Volcanoes*, ch. 4, p. 68. (A., 1899.)

1383. GLORY, REFLECTED—*The Light of Planets Not Their Own.*—Our ancestors were far from imagining that these luminous points wandering among the stars do not possess any real light of their own; that they are dark like the earth, and as large as she is; that several are even much larger and heavier than our world; that they are illuminated by the sun, like the earth and moon, neither more nor less; that their distance is small compared to that which separates us from the stars; that they form, with the earth, a family of which the sun is the father! Yes, that luminous point, for example, which shines like a star is Jupiter. It has itself no light, any more than the earth has, but it is illuminated by the sun; and as the earth shines from afar on account of this illumination, so it shines a luminous point in which is condensed all the light scattered over its immense disk. Place a stone on a black cloth in a chamber completely closed to the daylight, throw upon it the rays of the sun by means of an opening suitably arranged, and this stone will shine like the moon and like Jupiter. The planets are dark worlds like ours, and only shine by the solar light which they receive and reflect into space.—FLAMMARION *Popular Astronomy*, bk. iv, ch. 1, p. 330. (A.)

1384. GLORY VEILED FOR HUMAN WEAKNESS—*Blinding Effect of Sun's Light Overcome—Polarizing Eyepiece.*—The projecting apparatus is next removed and replaced by the polarizing eyepiece. Sir William Herschel used to avoid the blinding effects of the concentrated solar light by passing the rays through ink and water, but the phenomena of "polarization" have been used to better advantage in modern apparatus. [In this instrument] the light is polarized with three successive reflections through three tubes. By its aid the eye can be safely placed where the concentrated heat would otherwise melt iron. In practise I have often gazed through it at the sun's face without intermission from four to five hours, with no more fatigue or harm to the eye than in reading a book. By its aid the observer fills in the outline already projected on the paper.—LANGLEY *New Astronomy*, ch. 1, p. 18. (H. M. & Co., 1896.)

1385. GOD CAN REVEAL HIMSELF TO MAN—*Intuitive Perception of the Divine.*—The existence of a Being from whom our own being has been derived involves, at least, the possibility of some communication direct or indirect. Yet the impossibility or the improbability of any such communication is another of the assumptions continually involved in current theories about the origin of religion. Yet it is quite certain that no such assumption can be reasonably made. The perceptions of the human mind are accessible to the intimations of external truth through many avenues of approach. In its very structure it is made to be responsive to some of these intimations

by immediate apprehension. Man has that within him by which the invisible can be seen, and the inaudible can be heard, and the intangible can be felt. Not as the result of any reasoning, but by the same power by which it sees and feels the postulates on which all reasoning rests, the human mind may from the very first have felt that it was in contact with a Mind which was the fountain of its own.—ARGYLL *Unity of Nature*, ch. 11. p. 266. (Burt.)

1386. GOD, LATIN IDEA OF—*Separateness of the Deity vs. Greek Idea of Immanence.*—The general effect of this intellectual movement has been to discredit more than ever before the Latin idea of God as a power outside of the course of Nature and occasionally interfering with it. In all directions the process of evolution has been discovered, working after similar methods, and this has forced upon us the belief in the unity of Nature. We are thus driven to the Greek conception of God as the power working in and through Nature, without interference or infraction of law.—FISKE *Through Nature to God*, pt. iii, ch. 2, p. 147. (H. M. & Co., 1900.)

1387. GOD, SCIENTIFIC CONCEPTION OF—*Theologians Have Often Narrowed the Thought—Science Makes It Sublime.*—The author of "Ecce Homo" may be partially right when he says: "I think a bystander would say that, tho Christianity had in it something far higher and deeper and more ennobling, yet the average scientific man worships just at present a more awful, and, as it were, a greater deity than the average Christian. In so many Christians the idea of God has been degraded by childish and little-minded teaching; the Eternal and the Infinite and the All-embracing has been represented as the head of the clerical interest, as a sort of clergyman, as a sort of schoolmaster, as a sort of philanthropist. But the scientific man knows him to be eternal; in astronomy, in geology, he becomes familiar with the countless millenniums of his lifetime. The scientific man strains his mind actually to realize God's infinity. As far off as the fixed stars he traces him, 'distance inexpressible by numbers that have name.' Meanwhile, to the theologian, infinity and eternity are very much of empty words when applied to the object of his worship. He does not realize them in actual facts and definite computations" ("Natural Religion," p. 20).—DRUMMOND *Natural Law in the Spiritual World*, essay 4, p. 147. (H. Al.)

1388. GOD WORKS THROUGH SECOND CAUSES—*Beyond the Reach of Science the Fiat and Finger of God.*—"Whatsoever the Lord pleased, that did he in heaven, and in earth, in the seas, and all deep places. He causeth the vapors to ascend from the ends of the earth; he maketh lightnings for the rain; he bringeth the wind out of his treasuries" (Psalm cxxxv. 6-7).

Here, without any change of translation, we are told of the subserviency of the visible instruments to the invisible but real agency of him who wields them at his pleasure. In this passage the winds are plainly represented to us as the messengers of God, and the flaming fire as his servant. He changes no properties and no visible processes—working, not without the wind, but by it—not without the electric matter, but by it—not without the rain, but by it—not without the vapor, but by it. Let the philosopher tell how far back he can go in exploring the method and order of these respective agencies. Then we have only to point further back and ask on what evidence he can tell that the fiat and the finger of a God are not there. We grant the observed order to be invariable, save when God chooses to interpose by miracle. But whether he does or not—from that chamber of his hidden operations which philosophy has not found its way to, can he so direct all, so subordinate all, that whatever the Lord pleases, that does he in heaven and in earth, in the seas, and all deep places.—CHALMERS *Astronomical Discourses*, Suppl. Disc. ii, p. 244. (R. Ct., 1848.)

1389. GOD'S ETERNAL NOW—*The Past of Our Earth May Be Present Fact in Distant Worlds—An Ever-new Present as Light Speeds On.*—Events have happened on our earth and have been forgotten which, nevertheless, are at this very instant of my writing visible from some one or other of the orbs which people space, if only there are creatures on those orbs possessing such enhanced powers of vision as I have spoken of; and there is no event of such a nature as to be visible from standpoints without the earth which has not been thus rendered visible over and over again as the light-messages conveying its history have passed beyond star after star (in all directions from the side of the earth on which such events took place): no such event which will not be thus rendered visible over and over again hereafter as the light-messages travel onwards into the star depths for years, for centuries, for millions on millions of ages, until time shall be no more.

Now, the conception of such powers of vision in creatures made by God's hands may be regarded as fanciful, tho I apprehend that our ideas in such matters are very imperfect and feeble, and afford no measure of what is possible. But that the Almighty himself is cognizant of all these light-messages who can question? To him who is everywhere the light-record of all that has taken place on earth is being continually conveyed, the remembrance is ever present with him, "the eyes of the Lord are in every place beholding the evil and the good" [Prov. xv, 3]; "His eyes are upon the ways of man and he seeth all his goings" [Job xxxiv, 21].—PROCTOR *Expanse of Heaven*, p. 209. (L. G. & Co., 1897.)

1390. GODS OF SAVAGES LIKE THEIR WORSHIPERS—*Cannibal Divinities.*—Their [the Fijian] temples were pyramidal in form, and were often erected on terraced mounds, like those of Central America. They also venerated certain upright stones, resembling those which we call druidical. "The Feegeeans," says Mr. Hazlewood, "consider the gods as beings of like passions with themselves. They love and hate; they are proud and revengeful, and make war, and kill and eat each other, and are, in fact, savages and cannibals like themselves." "Cruelty," says Captain Erskine, "a craving for blood, and especially for human flesh as food, are characteristic of the gods."—AVEBURY *Prehistoric Times*, ch. 13, p. 433. (A., 1900.)

1391. GOLD MAN'S FIRST METAL—*Treasure among Savages—Progress from the Brilliant to the Useful.*—It is probable that gold was the metal which first attracted the attention of man; it is found in many rivers, and by its bright color would certainly strike even the rudest savages, who are known to be very fond of personal decoration. Silver does not appear to have been discovered until long after gold, and was apparently preceded by both copper and tin: for it rarely, if ever, occurs in tumuli of the Bronze Age; but however this may be, copper seems to have been the metal which first became of real importance to man; no doubt owing to the fact that its ores are abundant in many countries, and can be smelted without difficulty; and that, while iron is hardly ever found except in the form of ore, copper often occurs in a native condition, and can be beaten at once into shape. Thus, for instance, the North-American Indians obtained pure copper from the mines near Lake Superior and elsewhere, and hammered it at once into axes, bracelets, and other objects.—AVEBURY *Prehistoric Times*, ch. 1, p. 3. (A., 1900.)

1392. GOOD OUT OF SEEMING EVIL—*Terrible and Destructive Volcanic Forces Part of a Wise Economy.*—It may well be doubted whether the annual average of destruction to life and property caused by all kinds of subterranean action exceeds that produced either by floods or by hurricanes. Yet we know that the circulation of water and air over our globe are beneficial and necessary operations, and that the mischief occasionally wrought by the moving bodies of water and air is quite insignificant compared, with the good which they effect.

In the same way, we shall be able to show that the subterranean energies are necessary to the continued existence of our globe as a place fitted for the habitation of living beings, and that the mischievous and destructive effects of these energies bear but a small and insignificant proportion to the beneficial results with which they must be credited.—JUDD *Volcanoes*, ch. 10, p. 282. (A., 1899.)

1393. GOVERNMENT BY ABSTRACT REASONING—*Plato's "Republic"—Obliteration of Family Life.*—The ancient lawgivers were always aiming at standards of political society framed according to some abstract notions of their own as to how things ought to be, rather than upon any attempt to investigate the constitution of human nature as it actually is. . . . Perhaps, all things considered, the most odious conceptions of human society which the world has ever seen were the conceptions of an intellect certainly among the loftiest which has ever exercised its powers in speculative thought. Plato's Republic is an ideal state, founded on abstract conceptions of the mind, and one of its leading ideas is the destruction of family life and the annihilation of the family affections. And yet this result, odious and irrational as it is, was arrived at from reasoning which is not in itself odious, but which is false, chiefly because it takes no account of the facts of Nature. The welfare of the state was to be the one object of desire in every mind. All separate interests and affections were to be suppressed, and amongst these the very idea of special property in wife or child. The highest type of man was to be bred by the Republic as the highest type of dogs and horses is bred by an intelligent owner. [Grote's "Plato," vol. iii, p. 203.] Such are the humiliating results of abstract reasoning, pursued in ignorance of the great law that no purpose can be attained in Nature except by legitimate use of the means which Nature has supplied. For, as in the material world all her forces must be acknowledged and obeyed before they can be made to serve, so in the realm of mind there can be no success in attaining the highest moral ends until due honor has been assigned to those motives which arise out of the universal instincts of our race.—ARGYLL *Reign of Law*, ch. 7, p. 194. (Burt.)

1394. GOVERNMENT BY PHILOSOPHERS—*Liberty Not To Be Permitted.*—A few words will sufficiently express the outline of [Comte's] scheme. A corporation of philosophers, receiving a modest support from the state, surrounded by reverence, but peremptorily excluded, not only from all political power or employment, but from all riches, and all occupations except their own, are to have the entire direction of education, together with, not only the right and duty of advising and reproving all persons respecting both their public and their private life, but also a control (whether authoritative or only moral is not defined) over the speculative class itself, to prevent them from wasting time and ingenuity on inquiries and speculations of no value to mankind (among which he includes many now in high estimation), and compel them to employ all their powers on the investigations which may be judged, at the time, to be the most urgently important to the general welfare. The temporal

government which is to coexist with this spiritual authority consists of an aristocracy of capitalists, whose dignity and authority are to be in the ratio of the degree of generality of their conceptions and operations—bankers at the summit, merchants next, then manufacturers, and agriculturists at the bottom of the scale. No representative system, or other popular organization, by way of counterpoise to this governing power, is ever contemplated. The checks relied upon for preventing its abuse are the counsels and remonstrances of the spiritual power, and unlimited liberty of discussion and comment by all classes of inferiors. Of the mode in which either set of authorities should fulfil the office assigned to it, little is said in this treatise; but the general idea is, while regulating as little as possible by law, to make the pressure of opinion, directed by the spiritual power, so heavy on every individual, from the humblest to the most powerful, as to render legal obligation, in as many cases as possible, needless. Liberty and spontaneity on the part of individuals form no part of the scheme. M. Comte looks on them with as great jealousy as any scholastic pedagogue, or ecclesiastical director of consciences. Every particular of conduct, public or private, is to be open to the public eye, and to be kept, by the power of opinion, in the course which the spiritual corporation shall judge to be the most right. This is not a sufficiently tempting picture to have much chance of making converts rapidly, and the objections to the scheme are too obvious to need stating.—MILL *Positive Philosophy of Auguste Comte*, p. 110. (H. H. & Co., 1887.)

1395. GOVERNMENT, HARMONIOUS, OF THE UNIVERSE TAUGHT BY ARISTOTLE — *Germ of Undulatory Theory of Light.*—The idea of the harmonious government of the universe reveals itself in a distinct and exalted tone throughout the writings of Aristotle. All the phenomena of Nature are depicted in the "Physical Lectures" ("Auscultationes Physicæ") as moving, vital agents of one general cosmical force. Heaven and Nature (the telluric sphere of phenomena) depend upon the "unmoved motus of the universe." The "ordainer" and the ultimate cause of all sensuous changes must be regarded as something non-sensuous and distinct from all matter. Unity in the different expressions of material force is raised to the rank of a main principle, and these expressions of force are themselves always reduced to motions. Thus we find already in "The Book of the Soul" the germ of the undulatory theory of light. The sensation of sight is occasioned by a vibration—a movement of the medium between the eye and the object seen—and not by emissions from the object or the eye. Hearing is compared with sight, as sound is likewise a consequence of the vibration of the air.—HUMBOLDT *Cosmos*, vol. iii, p. 13. (H., 1897.)

1396. GOVERNMENT, PATERNAL, A BLESSING TO SAVAGES—Like so many other savage races, the North Americans are rapidly disappearing. Left to themselves they would perhaps have developed an indigenous civilization, but for ours they are unfit. Unable to compete with Europeans as equals, and too proud to work as inferiors, they have profited by intercourse with the superior race only where the paternal government of the Hudson's Bay Company has protected them both from the settlers and from themselves, has encouraged hunting, put an end to war, prevented the sale of spirits, and, in times of scarcity, provided food. Erelong almost the only remains of the Indian blood will, perhaps, be found in the territories of the Hudson's Bay Company.—AVEBURY *Prehistoric Times*, ch. 14, p. 505. (A., 1900.)

1397. GRAIN STORED BY ANTS—*Confirmation of Solomon's Observation.*—Sykes, in his account of an Indian ant, *Pheidole providens*, appears to have been the first of modern scientific authors to confirm the statements of Solomon. He states that the above-named species collects large stores of grass-seeds, on which it subsists from February to October. On one occasion he even observed the ants bringing up their stores of grain to dry them after the closing thunder-storms of the monsoon; an observation which has been since confirmed by other naturalists.—AVEBURY *Ants, Bees, and Wasps*, ch. 3, p. 60. (A., 1900.)

1398. GRANDEUR OF THE HUMAN SOUL—*Man, Astronomically Petty, Is Yet Great Enough To Measure the Universe.*—We see that the varied horizons discovered from the height of the elevated paths which the study of astronomy has led us to follow are not less interesting than astronomy itself. The attraction, almost universal, which draws the human mind towards the most abstruse and less usual results of science is, perhaps, the most singular trait of that restless curiosity which has been given to us in order that we may observe and know. Pythagoras was asked what was the characteristic mark of man. He replied, "The knowledge of truth for truth's sake." Is it not remarkable to see the human species, living on the productions of the fostering earth, according to the expression of Homer, applying itself in preference to purely intellectual sciences, and giving to them the greatest part of its attention, to the exclusion of those which have for their object health, feeding, material welfare, and, in short, all the arts without which the powerful organization of modern society cannot subsist? We feel a more lively and profound interest in studying astronomical conquests—as the distance of the stars, the nature of the sun, the planetary humanities, the destinies which await us in infinity and

eternity—than in a new route opened to commerce, a new sort of eatable, or a chemical discovery which may afterwards disturb numerous interests. Thus, of the three elements which form the essence of man—his wants, his affections, and his intelligence—it is the last-named faculty which obtains the preference. It is an advantage, especially to the young, to comprehend in their totality truths the possession of which does honor to the human mind. It is thus that we learn to rise above the petty interests of life, towards the higher regions to which the divine patriotism of the soul aspires.—FLAMMARION *Popular Astronomy*, bk. iii, ch. 7, p. 326. (A.)

1399. GRAVITATION A MYSTERY— *A Mental Inference to Explain Phenomena.*—Yet of the force of gravitation all we know is that it is a force of attraction operating between all the particles of matter in the exact measure which was ascertained by Newton—that is, "directly as the mass, and inversely as the square of the distance." This is the law. But it affords no sort of explanation of itself. What is the cause of this force—what is its source—what are the media of its operation—how is the exact uniformity of its proportions maintained?—these are questions which it is impossible not to ask, but which it is quite as impossible to answer. Sir John Herschel, in speaking of this force, has indicated in a passing sentence a few questions out of the many which arise. "No matter," he says, "from what ultimate causes the power called gravitation originates—be it a virtue lodged in the sun as its receptacle, or be it pressure from without, or the resultant of many pressures, or solicitation of unknown kinds, magnetic or electric, ethers or impulses," etc., etc. How little we have ascertained in this law, after all! Yet there is an immense and an instinctive pleasure in the contemplation of it. To analyze this pleasure is as difficult as to analyze the pleasure which the eye takes in beauty of form, or the pleasure which the ear takes in the harmonies of sound.—ARGYLL *Reign of Law*, ch. 2, p. 44. (Burt.)

1400. ——— ——— *A Statement of Conditions—The Cause Still To Seek—The Falling of an Apple Not Yet Accounted For.*—"Why does an apple fall to the ground?" is a question which has as great a significance to us now as it had before Newton was led, by pondering upon it, to the discovery of the law of gravitation. For that law only expresses the conditions of action of a universal force tending to draw together all masses of matter, while of the force itself it gives no account whatever. We recognize it by our own consciousness of effort in lifting a weight from the ground; and this recognition carries us from the sphere of physical into that of moral causation. For, as Sir John Herschel long ago pointed out, our consciousness of direct personal causation in the performance of a voluntary act leads us to regard what we call the "Forces of Nature" as the emanations of an all-pervading will, and those uniformities in their action which we term her "laws" as the manifestations of its unchanging continuity.—CARPENTER *Nature and Man*, lect. 15, p. 411. (A., 1889.)

1401. GRAVITATION A SIGN OF UNITY—*Moves Whole Mechanism of Heavens.*—There is one sign of unity which, of itself, carries us very far indeed. It is the sign given to us in the ties by which this world of ours is bound to the other worlds around it. There is no room for fancy here. The truths which have been reached in this matter have been reached by walking in the paths of rigorous demonstration. This earth is part of the vast mechanism of the heavens. The force, or forces, by which that mechanism is governed are forces which prevail not only in our own solar system, but, as there is reason to believe, through all space, and are determining, as astronomers tell us, the movement of our sun, with all its planets, round some distant center, of which we know neither the nature nor the place. Moreover, these same forces are equally prevailing on the surface of this earth itself. The whole of its physical phenomena are subject to the conditions which they impose.—ARGYLL *Unity of Nature*, ch. 1, p. 5. (Burt.)

1402. GRAVITATION ENABLES BIRDS TO FLY—*Difference between a Bird and a Balloon.*—It is remarkable that the force which seems so adverse—the force of gravitation drawing down all bodies to the earth—is the very force which is the principal one concerned in flight, and without which flight would be impossible. It is curious how completely this has been forgotten in almost all human attempts to navigate the air. Birds are not lighter than the air, but immensely heavier. If they were lighter than the air they might float, but they could not fly. This is the difference between a bird and a balloon. A balloon rises because it is lighter than the air, and floats upon it. Consequently it is incapable of being directed, because it possesses in itself no active force enabling it to resist the currents of the air in which it is immersed, and because, if it had such a force, it would have no fulcrum, or resisting medium against which to exert it. It becomes, as it were, part of the atmosphere, and must go with it where it goes. No bird is ever for an instant of time lighter than the air in which it flies; but being, on the contrary, always greatly heavier, it keeps possession of a force capable of supplying momentum, and therefore capable of overcoming any lesser force, such as the ordinary resistance of the atmosphere, and even of heavy gales of wind. The law of gravitation, therefore, is used in the flight of birds as one of the most essential of the

forces which are available for the accomplishment of the end in view.—ARGYLL *Reign of Law,* ch. 3, p. 78. (Burt.)

1403. GRAVITATION PROVED UNIVERSAL—*The Work of a Century of Astronomy—Laborious Climbing to Now Familiar Conception.*—The advance of astronomy in the eighteenth century ran in general an even and logical course. The age succeeding Newton's had for its special task to demonstrate the universal validity and trace the complex results of the law of gravitation. The accomplishment of that task occupied just one hundred years. It was virtually brought to a close when Laplace explained to the French Academy, November 19, 1787, the cause of the moon's accelerated motion. As a mere machine, the solar system, so far as it was then known, was found to be complete and intelligible in all its parts; and in the "Mécanique Céleste" its mechanical perfections were displayed under a form of majestic unity which fitly commemorated the successive triumphs of analytical genius over problems among the most arduous ever dealt with by the mind of man.—CLERKE *History of Astronomy,* int., p. 2. (Bl., 1893.)

1404. GRAVITATION SURPASSED BY MOLECULAR FORCES—*Power Involved in Expansion of Iron.*—The constituent molecules of bodies do not touch. It is thus, and thus only, that the expansion and the change of state of bodies under the influence of heat can be explained. We do not doubt the energy of the atomic forces in action around us. Let us heat 1 lb. of iron from 0 to 100 degrees, it will expand about $\frac{1}{800}$, a span imperceptible to the eye, and yet the force which has produced this expansion would be capable of lifting 12,000 lbs., and raising them to the height of one yard. The power of gravitation almost vanishes in comparison with these molecular forces; the attraction exercised by the earth on the weight of half a kilogram (about a pound) taken in a mass is nothing compared to the mutual attraction of its own molecules. In the combination of 1 lb. of hydrogen with 8 lbs. of oxygen to form water, work is performed capable of raising by 1 degree the temperature of 34,000 lbs. of water; or of lifting 15,000,000 lbs. to 1 yard high! These nine pounds of water in being formed have fallen molecularly down a precipice equal to that which would be passed over by a ton of 1,000 kilograms rolling down to 46,000 feet of depth.—FLAMMARION *Popular Astronomy,* bk. iii, ch. 7, p. 320. (A.)

1405. GREED BRINGS DESTRUCTION—*The Puma and Its Prey.*—The puma, after eating its fill, covers the carcass with many large bushes, and lies down to watch it. This habit is often the cause of its being discovered; for the condors, wheeling in the air, every now and then descend to partake of the feast, and being angrily driven away, rise all together on the wing. The Chileno Guaso then knows there is a lion watching his prey—the word is given—and men and dogs hurry to the chase. Sir F. Head says that a Gaucho in the pampas, upon merely seeing some condors wheeling in the air, cried "A lion!"—DARWIN *Naturalist's Voyage around the World,* ch. 12, p. 269. (A., 1898.)

1406. GROWTH AND DECAY PERVADE ALL NATURE—*"In the Beginning."*—"In the beginning God created the heaven and the earth. And the earth was without form, and void."

Whatever our speculations may be in regard to a "beginning," and when it was, it is written in the rocks, that, like the animals and plants upon its surface, the earth itself grew; that for countless ages, measured by years that no man can number, the earth has been gradually assuming its present form and composition, and that the processes of growth and decay are active every hour.—ELISHA GRAY *Nature's Miracles,* vol. i, ch. 1, p. 1. (F. H. & H., 1900.)

1407. GROWTH COMES ONLY FROM LIFE *(Matt. vi, 27)*—*Growth vs. Accretion—Christian Life a Growth.*—A boy not only grows without trying, but he cannot grow if he tries. No man by taking thought has ever added a cubit to his stature; nor has any man by mere working at his soul ever approached nearer to the stature of the Lord Jesus. The stature of the Lord Jesus was not itself reached by work, and he who thinks to approach its mystical height by anxious effort is really receding from it. Christ's life unfolded itself from a divine germ, planted centrally in His nature, which grew as naturally as a flower from a bud. This flower may be imitated; but one can always tell an artificial flower. The human form may be copied in wax, yet somehow one never fails to detect the difference. And this precisely is the difference between a native growth of Christian principle and the moral copy of it. The one is natural, the other mechanical. The one is a growth, the other an accretion.—DRUMMOND *Natural Law in the Spiritual World,* essay 3, p. 114. (H. Al.)

1408. GROWTH, GRADUAL, OF TRUTH—*Sudden Harvest of Discovery—Limited Work of Any Single Discoverer—Total Result Fulfils Divine Plan.*—Slowly, it is true, does the power of the mind give to man the mastery over the more hidden ways of Nature. One after another tries and fails, tho gradually accumulating the knowledge by which, in the end, the secret will be learned. At length the master-mind arrives which is to utilize the garnered knowledge of ages. On a sudden the scattered portions of the chain of evidence are linked together, and the chain is complete. A great work has then been achieved—a work which the Almighty had as fully intended that the human race should accomplish as any of those material successes by which men have ob-

tained mastery over Nature and the forces of Nature.—PROCTOR *Expanse of Heaven,* p. 106. (L. G. & Co., 1897.)

1409. GROWTH OF CORAL, RATE OF —*Anchor Preserved in Coral.*—At the island called Taaopoto, in the South Pacific, the anchor of a ship, wrecked about 50 years before, was observed in seven fathoms of water, still preserving its original form, but entirely incrusted by coral. This fact would seem to imply a slow rate of augmentation; but to form a correct estimate of the average rate must be very difficult, since it must vary not only according to the species of coral, but according to the circumstances under which each species may be placed: such, for example, as the depth from the surface, the quantity of light, the temperature of the water, its freedom from sand or mud, or the absence or presence of breakers, which is favorable to the growth of some kinds and is fatal to that of others.—LYELL *Principles of Geology,* ch. 50, p. 778. (A., 1854.)

1410. ——— ——— *Experiment to Determine.*—To ascertain the rise and progress of the coral family, and fix the number of species met with at Foul Point (lat. 17° 40′), twenty species of coral were taken off the reef and planted apart on a sandbank three feet deep at low water. Each portion weighed ten pounds, and was kept in its place by stakes. Similar quantities were placed in a clump and secured as the rest. This was done in December, 1830. In July following, each detached mass was nearly level with the sea at low water, quite immovable, and several feet long, stretching, like the parent reef, in the line of the coast-current from north to south. The masses accumulated in a clump were found equally increased, but some of the species in such unequal ratios as to be growing over each other. [Quoted from MS. thesis of Dr. Allan, of Forres, deposited in the library of Edinburgh University.]—DARWIN *Coral Reefs,* ch. 4, p. 104. (A., 1900.)

1411. GROWTH OF ELECTRIC AND MAGNETIC DISCOVERY—*A True Intellectual Rise.*—After the lapse of centuries a new capacity of the lodestone became revealed in its polarity, or the appearance of opposite effects at opposite ends; then came the first utilization of the knowledge thus far gained, in the mariner's compass, leading to the discovery of the New World, and the throwing wide of all the portals of the Old to trade and civilization.

The predominance of the magnet in human thought was yielded to the amber, when the strange power of the latter was found to exist also in other things. The keen-eyed discoverers saw this new force annihilate time and space, and flash into light; pursued it even to its hiding-place in the clouds; beheld it grow from the feeble amber-soul into the mighty thunderbolt; watched it until the whole universe showed itself pervaded with it.

This was a true intellectual rise. It was the intellect at work building the universe of which it is the key; finding anew that Nature also is working in every detail after the laws of the human mind.—PARK BENJAMIN *Intellectual Rise in Electricity,* int., p. 13. (J. W., 1898.)

1412. GROWTH OF LOYALTY, HEROISM, AND PATRIOTISM—As the maternal instinct had been cultivated for thousands of generations before clanship came into existence, so for many succeeding ages of turbulence the patriotic instinct, which prompts to the defense of home, was cultivated under penalty of death. Clans defended by weakly loyal or cowardly warriors were sure to perish. Unflinching bravery and devoted patriotism were virtues necessary to the survival of the community, and were thus preserved until at the dawn of historic times, in the most grandly militant of clan societies, we find the word *virtus* connoting just these qualities, and no sooner does the fateful gulf yawn open in the forum than a Curtius joyfully leaps into it, that the commonwealth may be preserved from harm.—FISKE *Through Nature to God,* pt. ii, ch. 9, p. 104. (H. M. & Co., 1900.)

1413. GROWTH, SLOW, OF PATERNAL VIRTUES—*Bird Parents United in Love—Little Fatherhood among Mammalia—Among Carnivora Fathers Dangerous to Their Offspring.*—If maternity was at a feeble level in the lower reaches of Nature, paternity was non-existent. Among a few invertebrates the male parent took a passing share in the care of the egg, but it is not until we are all but at the top that fatherly interest finds any real expression. Among the birds, the parents unite together in most cases to build the nest, the father doing the rough work of bringing in moss and twigs, while the more trusty mother does the actual work. When the eggs are laid, the male parent also takes his turn at incubation; supplies food and protection, and lingers round the place of birth to defend the fledglings to the last. When we leave the birds, however, and pass on to the mammals, the fathers are nearly all backsliders. Many are not only indifferent to their young, but hostile; and among the carnivora the mothers have frequently to hide their little ones [lest the father should eat them].—DRUMMOND *Ascent of Man,* ch. 9, p. 294. (J. P., 1900.)

1414. GULF ASSUMED BETWEEN MAN AND NATURE—*The Human Mind a Part of Nature.*—It [the charge of anthropomorphism] assumes that the relation between the human mind and the system of Nature in which we live is fundamentally a relation of contrast and not of harmony—a relation of difference so deep and so complete that the intellectual impressions

which Nature gives to us are not presumably right, but, on the contrary, are presumably wrong. . . . Man is no part of Nature. His mind does not reflect her laws. On the contrary, his intellect is separated by such a gulf from those laws that it tends of necessity to misinterpret and misconceive them. The very forms in which our perceptions and our conceptions are molded are forms which [are assumed to] have no counterpart outside the organism through which we see and think.—ARGYLL *Unity of Nature*, ch. 5, p. 102. (Burt.)

1415. GULF BETWEEN MAN AND BRUTE—No one is more strongly convinced than I am of the vastness of the gulf between civilized man and the brutes; or is more certain that whether *from* them or not, he is assuredly not *of* them. No one is less disposed to think lightly of the present dignity, or despairingly of the future hopes, of the only consciously intelligent denizen of this world.—HUXLEY *Man's Place in Nature*, p. 234. (Hum.)

1416. GULF BETWEEN ORGANIC AND INORGANIC—Between the living and the non-living there is a great gulf fixed; and the indissoluble connection which somehow, nevertheless, we know to exist between them is a connection which does not fill up that gulf, but is kept up by some bridge being, as it were, artificially built across it. This unity, like the other unities of nature, is not a unity consisting of mere continuity of substance. It is not founded upon sameness, but, on the contrary, rather upon difference, and even upon antagonisms.—ARGYLL *Unity of Nature*, ch. 2, p. 33. (Burt.)

1417. GULF STREAM, INFLUENCE OF—*Moderates Climate of Western Europe.*—But the effects of the Gulf Stream on the climate of the North Atlantic Ocean are far more remarkable. This most powerful of known currents has its source in the Gulf or Sea of Mexico, which, like the Mediterranean and other close seas in temperate or low latitudes, is warmer than the open ocean in the same parallels. The temperature of the Mexican sea in summer is, according to Rennel, 86° F., or at least 7° above that of the Atlantic in the same latitude. From this great reservoir or caldron of warm water a constant current pours forth through the Straits of Bahama at the rate of 3 or 4 miles an hour; it crosses the ocean in a northeasterly direction, skirting the great Bank of Newfoundland, where it still retains a temperature of 8° above that of the surrounding sea. It reaches the Azores in about 78 days, after flowing nearly 3,000 geographical miles, and from thence it sometimes extends its course a thousand miles farther, so as to reach the Bay of Biscay, still retaining an excess of 5° above the mean temperature of that sea. As it has been known to arrive there in the months of November and January, it may tend greatly to moderate the cold of winter in countries on the west of Europe.—LYELL *Principles of Geology*, bk. i, ch. 7, p. 95. (A., 1854.)

1418. HABIT A RESULT OF BODILY ORGANISM—I believe that we are subject to the law of habit in consequence of the fact that we have bodies. The plasticity of the living matter of our nervous system, in short, is the reason why we do a thing with difficulty the first time, but soon do it more and more easily, and finally, with sufficient practise, do it semi-mechanically, or with hardly any consciousness at all. Our nervous systems have (in Dr. Carpenter's words) *grown* to the way in which they have been exercised, just as a sheet of paper or a coat, once creased or folded, tends to fall forever afterward into the same identical folds. Habit is thus a second nature.—JAMES *Talks to Teachers*, ch. 8, p. 65. (H. H. & Co., 1900.)

1419. HABIT BEST CONQUERED BY SHARP AND SUDDEN CHANGE—*"Tapering-off" Rarely Practicable.*—The question of "tapering-off," in abandoning such habits as drink and opium-indulgence, comes in here, and is a question about which experts differ within certain limits, and in regard to what may be best for an individual case. In the main, however, all expert opinion would agree that abrupt acquisition of the new habit is the best way, *if there be a real possibility of carrying it out.* We must be careful not to give the will so stiff a task as to insure its defeat at the very outset; but, *provided one can stand it,* a sharp period of suffering, and then a free time, is the best thing to aim at, whether in giving up a habit like that of opium, or in simply changing one's hours of rising or of work. It is surprising how soon a desire will die of inanition if it be *never* fed.—JAMES *Psychology*, vol. i, ch. 4, p. 124. (H. H. & Co., 1899.)

1420. HABIT, HEREDITY OF—*Horses, Dogs, and Birds, Apparent Heredity among.*—Darwin says, "A horse is trained to certain paces, and the colt inherits similar consensual movements." But selection of the constitutional tendency to these paces, and imitation of the mother by the colt, may have been the real causes. The evidence, to be satisfactory, should show that such influences were excluded. Men acquire proficiency in swimming, waltzing, walking, smoking, languages, handicrafts, religious beliefs, etc., but the children only appear to inherit the innate abilities or constitutional proclivities of their parents. Even the songs of birds, including their call-notes, are no more inherited than is language by man ("Descent of Man," p. 47). They are learned from the parent. Nestlings, which acquire the song of a distinct species, "teach and transmit their new song to their offspring." If use-inheritance has not fixed the song of birds, why should we suppose that in a single generation it has transmitted a new-

ly taught method of walking or trotting? It is alleged that dogs inherit the intelligence acquired by association with man, and that retrievers inherit the effects of their training. But selection and imitation are so potent that the additional hypothesis of use-inheritance seems perfectly superfluous. Where intelligence is not highly valued and carefully promoted by selection, the intelligence derivable from association with man does not appear to be inherited. Lap-dogs, for instance, are often remarkably stupid.—BALL *Are the Effects of Use and Disuse Inherited?* p. 31. (Hum., 1891.)

1421. HABIT, HYPNOTIC, FASCINATION OF—Frequent hypnotizing may lead in the long run to an irresistible passion for the hypnotic sleep, in which case the impulse to obtain it acts like the morphin habit or habituation to any particular stimulant or sedative. The confirmed hypnotic will try in every possible way to procure the enjoyment which he craves.—WUNDT *Psychology*, lect. 22, p. 331. (Son. & Co., 1896.)

1422. HABIT, IMPERIOUSNESS OF—*Unconscious Profanity—Anecdote of Military Officer.*—The following case, recently communicated to the writer, shows how strongly the mode of expression of our ideas is influenced by habit; and how, after the chain would seem to have been completely broken, it may come to renew itself when the circumstances recur under which it had been formed:

A military officer, who had seen much hard service at a time when a command was scarcely ever given without the accompaniment of an oath, and who had thus acquired the habit of continual swearing, determined, on retiring into private life, to do his best to forego this practise; and by keeping a constant check upon himself, with the assistance of the friendly monitions of others, he entirely succeeded. After the lapse of many years, however, he found himself called upon to perform some military duty; and, in the discharge of it, he used much of the bad language to which he had formerly accustomed himself. A friend who happened to notice this, having afterwards expressed his regret that he should have relapsed into his old habit of swearing, the officer assured him (and he was a man whose word could be implicitly relied on) that he was not at the time in the least degree conscious of uttering an oath, and that he had not the slightest recollection of having done so.—CARPENTER *Mental Physiology*, bk. i, ch. 6, p. 282. (A., 1900.)

1423. HABIT OF DOING RIGHT—*Preparation for Instantaneous Action—The Habits of a Nation.*—I consider the great object of intellectual education to be, not only to teach the pupils how to *think*, but how to *act* and to *do*, and I place great stress upon the early education of the *habits*. And this kind of training may be extended beyond the mental processes to the moral principles; the pupil may be taught on all occasions habitually and promptly, almost without thought, to act properly in any case that may occur, and this in the practical duties of life is of the highest importance. We are frequently required to act from the impulse of the moment, and have no time to deduce our course from the moral principles of the act. An individual can be educated to a strict regard for truth, to deeds of courage in rescuing others from danger, to acts of benevolence, of generosity, and justice; or, on the other hand, tho his mind may be well stored with moral precepts, he may be allowed to fall into opposite habits alike prejudicial to himself and to those with whom he is associated. He may "know the right, and yet the wrong pursue."

Man is the creature of habit; it is to him more than second nature; but unfortunately, while bad habits are acquired with readiness, on account of the natural desire to gratify our passions and appetites, good habits can only be acquired by unremitting watchfulness and labor. The combined habits of individuals form the habits of a nation, and these can only be molded . . . by the coercive labor of the instructor judiciously applied.—HENRY *Thoughts on Education (Scientific Writings*, vol. i, p. 340). (Sm. Inst., 1886.)

1424. HABITAT, ADAPTATION OF ANIMALS TO—*Protective Mimicry.*—Even the popular mind has been struck with the curious adaptation of nearly all animals to their habitat, for example in the matter of color. The sandy hue of the sole and flounder, the white of the polar bear, with its suggestion of arctic snows, the stripes of the Bengal tiger—as if the actual reeds of its native jungle had nature-printed themselves on its hide—these, and a hundred others which will occur to every one, are marked instances of adaptation to environment induced, by natural selection or otherwise, for the purpose, obviously in these cases at least, of protection.—DRUMMOND *Natural Law in the Spiritual World*, essay 7, p. 233. (H. Al.)

1425. HABITAT OF HUMMING-BIRDS—*Species Limited to a Single Mountain.*—In contrast with these species of extended range, there are many species [of humming-birds] whose habitat is confined, perhaps, to a single mountain, and there are a few which never have been seen beyond the edges of some extinct volcano, whose crater is now filled with a special flora. Many of the great mountains of the Andes have each of them species peculiar to themselves. On Chimborazo and Cotopaxi, and other summits, special forms of humming-birds are found in special zones of vegetation even close up to the limits of perpetual snow.

Again, many of the islands have species peculiar to themselves. The little island of Juan Fernandez, 300 miles from the mainland, has three species peculiar to itself, of which two are so distinct from all others known that they cannot for a moment be confounded with any of them.—ARGYLL *Reign of Law,* ch. 5, p. 135. (Burt.)

1426. HABITS FIXED IN YOUTH—*All Later Life Dependent on Early Years.*—If a boy grows up alone at the age of games and sports, and learns neither to play ball, nor row, nor sail, nor ride, nor skate, nor fish, nor shoot, probably he will be sedentary to the end of his days; and, tho the best of opportunities be afforded him for learning these things later, it is a hundred to one but he will pass them by and shrink back from the effort of taking those necessary first steps the prospect of which, at an earlier age, would have filled him with eager delight. The sexual passion expires after a protracted reign; but it is well known that its peculiar manifestations in a given individual depend almost entirely on the habits he may form during the early period of its activity. Exposure to bad company then makes him a loose liver all his days; chastity kept at first makes the same easy later on.—JAMES *Psychology,* vol. ii, ch. 24, p. 401. (H. H. & Co., 1899.)

1427. HABITS, GOOD AS WELL AS BAD—The fact is that our virtues are habits as much as our vices. All our life, so far as it has definite form, is but a mass of habits—practical, emotional, and intellectual—systematically organized for our weal or woe, and bearing us irresistibly toward our destiny, whatever the latter may be.—JAMES *Talks to Teachers,* ch. 8, p. 64. (H. H. & Co., 1900.)

1428. HABITS SHOW MAN'S COMPOSITE NATURE—There is no part of man's composite nature in which the intimate relation between mind and body is more obvious than it is in the formation of habitual modes of activity, whether psychical or corporeal; the former, like the latter, being entirely conformable to the laws which express the ordinary course of the nutritive operations.—CARPENTER *Mental Physiology,* bk. i, ch. 8, p. 337. (A., 1900.)

1429. HAECKEL AND MONISM—*Body without a Soul—Universe without a Spirit.*—Ernst Haeckel is an eminent comparative anatomist and physiologist, who has earned a wide and deserved reputation by his able and laborious studies of the calcareous sponges, the radiolarians, and other low forms of life. . . . He is not merely an evolutionist, but what he terms a "monist," and the monistic philosophy, as defined by him, includes certain negations and certain positive principles of a most comprehensive and important character. It implies the denial of all spiritual or immaterial existence. Man is to the monist merely a physiological machine, and Nature is only a greater self-existing and spontaneously moving aggregate of forces. Monism can thus altogether dispense with a creative will as originating Nature, and adopts the other alternative of self-existence or causelessness for the universe and all its phenomena. Again, the monistic doctrine necessarily implies that man, the animal, the plant, and the mineral are only successive stages of the evolution of the same primordial matter, constituting thus a connected chain of being, all the parts of which sprang spontaneously from each other. Lastly, as the admixture of primitive matter and force would itself be a sort of dualism, Haeckel regards these as ultimately one, and apparently resolves the origin of the universe into the operation of a self-existing energy having in itself the potency of all things. After all, this may be said to be an approximation to the idea of a Creator, but not a living and willing Creator.—DAWSON *Facts and Fancies in Modern Science,* lect. 1, p. 54. (A. B. P. S.)

1430. HALF-TRUTH, A, TERRIFIES—*Biela's Comet Crosses the Earth's Orbit—False Alarm Given by Pseudo-science.*—In calculating the epoch of the reappearance of the new body [Biela's comet], Damoiseau had found that the comet would, on October 29, 1832, before midnight, cross the plane in which the earth moves at the only place where a comet would be likely to encounter the earth. The passage of the body would, according to calculation, take place in the plane, but a little inside the earth's orbit, and at a distance equal to four and two-thirds terrestrial radii. As the length of the comet's radius was equal to five and one-third terrestrial radii, it was probable from all the evidence that on October 29, 1832, before midnight, a part of the terrestrial orbit would be occupied by the comet.

These results, supported by all desirable scientific authority, were brought by the newspapers to the notice of the public; we may imagine the profound sensation which they produced. It was a fact! the end of time was near! the earth was about to be shattered, pulverized, annihilated by the shock of the comet! Such was the subject of all conversation. The strongest minds were for a moment disturbed.

But a question remained to be asked, and the newspapers had neither stated it nor even anticipated it. At what place in its immense orbit would the earth be found on October 29, 1832, before midnight, at the moment when the comet would cross this orbit at one of its nodes? Calculation very quickly settled this difficulty. Arago wrote in the *Annuaire* for 1832: "The passage of the comet will take place very near *a certain point* of the terrestrial orbit on October 29, before midnight; well, the earth will not reach the *same point* till the morning of November 30—that is to say, *more than a*

month after. We have now only to recollect that the mean velocity of the earth in its orbit is 1,670,000 miles a day, and a very simple calculation will prove that *the comet will pass at fifty millions of miles from the earth.*"—FLAMMARION *Popular Astronomy*, bk. v, ch. 1, p. 483. (A.)

1431. HALLUCINATION PRODUCED BY ACONITE—*Unreality Recognized.*—[The following incident] is recorded of himself by Dr. Laycock:

"On a certain night, when a sufferer from severe pain and great weakness, he took one drop of Fleming's tincture of aconite, and slept. About midnight he became sensible of a novel state of perception, obscure at first, but shaped at last into strains of grand aerial music in cadences of exquisite harmony, now dying away round mountains in infinite perspective, now pealing along oceanlike valleys. Knowing by previous studies that it was a hallucination of perception, he at last listened to ascertain the cause, and found it was the rattle of a midnight train entering an adjoining railway station. Thus, under the changes induced in the brain by a drop of tincture of aconite, the harsh rattle of the iron vibrating on the air in the silence of a summer midnight was changed into harplike aerial music, such not only as 'ear had not heard.' but no conceivable art of man could realize. Associated therewith was also a suggested terrestrial vision of space of infinite extent and grandeur."—CARPENTER *Mental Physiology*, bk. ii, ch. 17, p. 643. (A., 1900.)

1432. HAMMER A RELIC OF STONE AGE—*History Preserved in Its Name.*—While the club has been generally a weapon, the hammer has been generally an implement. Its history begins with the smooth heavy pebble held in the hand, such as African blacksmiths to this day forge their iron with, on another smooth stone as anvil. It was a great improvement to fasten the stone hammer on a handle; this was done in very ancient times, as is seen by the stone heads being grooved or bored on purpose. . . . Tho the iron hammer has superseded these, a trace of the older use of stone remains in our very name *hammer*, which is the old Scandinavian *hamarr*, meaning both rock and hammer.—TYLOR *Anthropology*, ch. 8, p. 184. (A., 1899.)

1433. HAND GIVES MAN PREEMINENCE—*The Use of the Hands Develops the Intellect.*—How far the value of the hand as a mechanical instrument depends on this opposability [of the thumb, found only in the human hand], any one may satisfy himself by using his hand with the thumb stiff. It is plain that man's hand, enabling him to shape and wield weapons and tools to subdue Nature to his own ends, is one cause of his standing first among animals. It is not so obvious, but it is true, that his intellectual development must have been in no small degree gained by the use of his hands. From handling objects, putting them in different positions, and setting them side by side, he was led to those simplest kinds of comparing and measuring which are the first elements of exact knowledge, or science. —TYLOR *Anthropology*, ch. 2, p. 43. (A., 1899.)

1434. HAPPINESS INVOLVES AN ELEMENT OF PAIN—*Love Makes Sacrifice Painless.*—In our best happiness, then, what we otherwise term pain is swallowed up. It is embodied and mixed up in the joy. For do we not despise and loathe a man whose only thought in that which he calls love is of the pleasure he can receive? And, further, by taking away the love, its sacrifices would be felt as pain: pain emerges, or comes out, from this joy by a taking away, or absence. And its presence, to one who should be loving, might imply no evil state around him, but only something wanting in himself. For the very same things may be to us either painful, or in the highest degree productive of delight, of a delight which could not be without them.—HINTON *The Mystery of Pain*, p. 21. (Hum., 1893.)

1435. HAPPINESS VS. PERFECTED CHARACTER—A world of completed happiness might well be a world of quiescence, of stagnation, of automatism, of blankness; the dynamics of evolution would have no place in it. But suppose we say that the ultimate goal of the ethical process is the perfecting of human character? This form of statement contains far more than the other. Consummation of happiness is a natural outcome of the perfecting of character, but that perfecting can be achieved only through struggle, through discipline, through resistance. It is for him that overcometh that the crown of life is reserved. The consummate product of a world of evolution is the character that creates happiness, that is replete with dynamic possibilities of fresh life and activity in directions forever new. Such a character is the reflected image of God, and in it are contained the promise and potency of life everlasting. —FISKE *Through Nature to God*, pt. ii, ch. 9, p. 115. (H. M. & Co., 1900.)

1436. HARBORS FORMED BY CORAL REEFS—*Great Prospective Value.*—The harbors which are produced by the reef-building corals, together with the various marine animals and plants which are associated with them, are among the most interesting and important of all classes of havens. They are not only in origin the most peculiar of all inlets of the sea, but the conditions of their development and the circumstances which lead to their preservation and destruction are also curious and noteworthy. Moreover, in the district of southern Florida organic reefs of this nature are numerous and extensive, and the ports which they form, tho as yet relatively little used, are destined in course of time to have great value to this country.—SHALER *Sea and Land* p. 203. (S., 1894.)

1437. HARMONY AMID DIVERSITY —*Relative Size of Sun and Planets—Great and Small in Balanced Movement.*—Let the reader consider a terrestrial globe three inches in diameter, and search out on that globe the tiny triangular speck which represents Great Britain. Then let him endeavor to picture the town in which he lives as represented by the minutest pin-mark that could possibly be made upon this speck. He will then have formed some conception, tho but an inadequate one, of the enormous dimensions of the earth's globe, compared with the scene in which his daily life is cast. Now, on the same scale, the sun would be represented by a globe about twice the height of an ordinary sitting-room. A room about twenty-six feet in length, and height, and breadth, would be required to contain the representation of the sun's globe on this scale, while the globe representing the earth could be placed in a moderately large goblet.

Such is the body which sways the motions of the solar system. The largest of his family, the giant Jupiter, tho of dimensions which dwarf those of the earth or Venus almost to nothingness, would yet only be represented by a thirty-two-inch globe on the scale which gives to the sun the enormous volume I have spoken of. Saturn would have a diameter of about twenty-eight inches, his ring measuring about five feet in its extreme span. Uranus and Neptune would be little more than a foot in diameter, and all the minor planets would be less than the three-inch earth. . . . The sun outweighs fully 730 times the combined mass of all the planets which circle around him.—PROCTOR *Other Worlds than Ours*, ch. 2, p. 33. (Burt.)

1438. HARMONY OF NATURE—*Ancient and Recent Features of Landscape Perfectly Blend.*—There is nothing, indeed, so calculated to instruct the geologist as the striking manner in which the recent volcanic hills of Ischia . . . blend with the surrounding landscape. Nothing seems wanting or redundant; every part of the picture is in such perfect harmony with the rest that the whole has the appearance of having been called into existence by a single effort of creative power. Yet what other result could we have anticipated if Nature has ever been governed by the same laws? Each new mountain thrown up—each new tract of land raised or depressed by earthquakes—should be in perfect accordance with those previously formed.—LYELL *Principles of Geology*, bk. ii, ch. 23, p. 373. (A., 1854.)

1439. ——— ——— *Gravity and the Flowers—The Whole Earth Enlisted To Hold the Snowdrop in Position—Our Flowers Could Not Grow on Mars.*—Another illustration, and a very beautiful one, is pointed out by Whewell in the positions of flowers. "Some flowers grow with the hollow of their cup upwards; others 'hang the pensive head' and turn the opening downwards." It is obvious that an increase of gravity would force the upright plants to hang their heads, while a decrease to the value of gravity which actually exists in Mars would cause the drooping heads to stand erect. But it has been shown by Linnæus that on the position of the heads of flowers, combined with the greater or less length of the pistil and stamens, depends the fertility of the plant. So that, as Whewell remarks, "the whole mass of the earth, from pole to pole, and from circumference to center, is employed in keeping a snowdrop in the position most suited to the promotion of its vegetable health."—PROCTOR *Expanse of Heaven*, p. 72. (L. G. & Co., 1897.)

1440. HARMONY OF NATURE AND OF THE HUMAN MIND—How can it be true that man is so outside of that unity [of Nature] that the very notion of seeing anything like himself in it is the greatest of all philosophical heresies? Does not the very possibility of science consist in the possibility of reducing all natural phenomena to purely natural conceptions, which must be related to the intellect of man when they are worked out and apprehended by it? And if, according to the latest theories, man is himself a product of evolution, and is, therefore, in every atom of his body and in every function of his mind a part and a child of Nature, is it not in the highest degree illogical so to separate him from it as to condemn him for seeing in it some image of himself? If he is its product and its child, is it not certain that he is right when he sees and feels the indissoluble bonds of unity which unite him to the great system of things in which he lives?—ARGYLL *Unity of Nature*, ch. 8, p. 165. (Burt.)

1441. HARMONY OF THE UNIVERSE —*Gravitation Proved Universal — Discovery of Neptune—Newton Finds a Law—The Law Enables Astronomers To Find an Unknown World.*—This discovery [of Neptune] seems to me in some respects even more striking than Newton's discovery of the law of gravitation. Newton explained the laws according to which known objects move; Adams and Le Verrier showed where a hitherto unknown object would be found when telescopes were turned to that part of the heavens. Newton recognized laws hitherto unknown. Adams and Le Verrier by abstract reasoning inferred the existence of a world which men as yet had never seen.—PROCTOR *Expanse of Heaven*, p. 122. (L. G. & Co., 1897.)

1442. HARP DERIVED FROM BOWSTRING—*The Piano a Perfected Harp.*—It is told in the "Odyssey" (xxi. 410) how the avenging hero, when he has strung his mighty bow compact of wood and horn, gives the stretched string a twang that makes it sing like a swallow in a soft tone

beautifully. One might well guess that the strung bow of the warrior would naturally become a musical instrument, but, what is more, it really is so used. The Damara in South Africa finds pleasure in the faint tones heard by striking the tight bowstring with a little stick. The Zulu despises the bow as a cowardly weapon, but he still uses it for music; his music-bow has a ring slid along the string to alter the note, and is also provided with a hollow gourd [held behind the bow against the breast] acting as a resonator or sounding-box to strengthen the feeble twang. The ancient Egyptian harp [simply a curved strip of wood, with a few strings stretched across it] may have been developed from such a rude music-bow, the wooden back being now made hollow so as to be bow and resonator in one, while across it are strung several strings of different lengths. All ancient harps, Assyrian, Persian, even old Irish, were made on this plan, yet we can see at a glance that it was defective, the bending of the wooden back putting the strings out of tune. It was not till modern ages that the improvement was made of completing the harp with the front pillar, which makes the whole frame rigid and firm. . . . The harp, tho now made more perfect than of old, is losing its ancient place in music; but the reason of this is easy to see—it has been supplanted by modern instruments which have come from it. The very form of a grand piano shows that it is a harp laid on one side in a case, and its strings not plucked with the fingers, but struck with hammers worked from a keyboard. It is the latest development from the bowstring of the prehistoric warrior.—TYLOR *Anthropology*, ch. 12, p. 295. (A., 1899.)

1443. HARVEST, GREAT, FROM SCANTY SOWING—*Few Original Concepts in Sanskrit—All India's Languages Therefrom.*—In analyzing the Sanskrit language, Professor Max Müller ["Science of Thought," p. 549] reduces its whole vocabulary to 121 roots—the 121 "original concepts." "These 121 concepts constitute the stock-in-trade with which I maintain that every thought that has ever passed through the mind of India, so far as known to us in its literature, has been expressed. It would have been easy to reduce that number still further, for there are several among them which could be ranged together under more general concepts. But I leave this further reduction to others, being satisfied as a first attempt with having shown how small a number of seeds may produce, and has produced, the enormous intellectual vegetation that has covered the soil of India from the most distant antiquity to the present day."—DRUMMOND *Ascent of Man*, ch. 5, p. 180. (J. P. & Co., 1900.)

1444. HAWAII, VOLCANOES OF—*Vast River of Melted Rock—Mauna Loa.*—We learn from the valuable observations made by Mr. Dana on the active volcanoes of the Sandwich Islands, that large sheets of compact basaltic lava have been poured out of craters at the top or near the summits of flattened domes higher than Etna, as in the case of Mount Loa, for example, where a copious stream two miles broad and twenty-five miles long proceeded from an opening 13,000 feet above the level of the sea. The usual slope of these sheets of lava is between 5° and 10°; but Mr. Dana convinced himself that, owing to the suddenness with which they cool in the air, some lavas may occasionally form on slopes equaling 25°, and still preserve a considerable compactness of texture. It is even proved, he says, from what he saw in the great lateral crater of Kilauea, on the flanks of Mount Loa, that a mass of such melted rock may consolidate at an inclination of 30°, and be continuous for 300 or 400 feet. Such masses are narrow, he admits, "but if the source had been more generous, they would have had a greater breadth, and by a succession of ejections, overspreading each cooled layer, a considerable thickness might have been attained." The same author has also shown . . . that in the "cinder cones" of the Sandwich Islands the strata have an original inclination of between 35° and 40°.—LYELL *Principles of Geology*, bk. ii, ch. 24, p. 383. (A., 1854.)

1445. HAWK THE FARMER'S ALLY—"*Chicken-hawk*" *Lives Chiefly on Mice and Batrachians and Insects.*—The voices of hawks are in keeping with their dispositions, and, while their lives typify all that is fierce and cruel, no birds are more often wrongly accused and falsely persecuted than our birds of prey. To kill one is regarded as an act of special merit; to spare one seems to place a premium on crime. Still, these birds are among the best friends of the farmer. There are but two of our common species, Cooper's and the sharp-shinned, who habitually feed on birds and poultry. Our other common species are, without exception, invaluable aids to the agriculturist in preventing the undue increase of the small rodents so destructive to crops. . . .

The red-shouldered hawk, to which the name chicken- or hen-hawk is often applied, has been found to live largely on small mammals, reptiles, batrachians, and insects.—CHAPMAN *Bird-Life*, ch. 7, p. 116. (A., 1900.)

1446. HEALTH BY REMOVAL OF IMPURITIES—*The Elbe below Hamburg.*—In 1893 Koch brought out his monograph upon "Water Filtration and Cholera," and his work had a deservedly great influence upon the whole question. He shows how the careful filtration of water supplied to Altona from the Elbe saved the town from the epidemic of cholera which came upon Hamburg as a result of drinking unfiltered water, altho Altona is situated several miles

below Hamburg, and its drinking-water is taken from the river after it has received the sewage of Hamburg.—NEWMAN *Bacteria*, ch. 2, p. 75. (G. P. P., 1899.)

1447. HEALTH CONDUCES TO MORALITY—*Interaction of Matter and Spirit.*—There is assuredly morality in the oxygen of the mountains, as there is immorality in the miasma of a marsh, and a higher power than mere brute force lies latent in Alpine mutton. We are recognizing more and more the influence of physical elements in the conduct of life, for when the blood flows in a purer current the heart is capable of a higher glow. Spirit and matter are interfused; the Alps improve us totally, and we return from their precipices wiser as well as stronger men.—TYNDALL *Hours of Exercise in the Alps*, ch. 14, p. 155. (A., 1898.)

1448. HEALTH IN TROPICAL LANDS—*Danger of Excesses in Food—Alcoholic Stimulants Perilous.*—Englishmen, accustomed to an active life at home, and a climate demanding much fuel-food for the maintenance of animal heat, go to India, crammed, maybe, with Latin, but ignorant of the laws of health; cheap servants promote indolence, tropical heat diminishes respiratory oxidation, and the appetite naturally fails.

Instead of understanding this failure as an admonition to take smaller quantities of food, or food of less nutritive and combustive value, such as carbohydrates instead of hydrocarbons and albuminoids, they regard it as a symptom of ill-health, and take curries, bitter ale, and other tonics or appetizing condiments, which, however mischievous in England, are far more so here.

I know several men who have lived rationally in India, and they all agree that the climate is especially favorable to longevity, provided bitter beer and all other alcoholic drinks, all peppery condiments, and flesh foods are avoided. The most remarkable example of vigorous old age I have ever met was a retired colonel eighty-two years of age, who had risen from the ranks, and had been fifty-five years in India without furlough; drunk no alcohol during that period; was a vegetarian in India, tho not so in his native land. I guessed his age to be somewhere about sixty. He was a Scotchman, and an ardent student of the works of both George and Dr. Andrew Combe.—WILLIAMS *Chemistry of Cookery*, ch. 15, p. 261. (A., 1900.)

1449. HEARING, SENSE OF, IN BEES—*Seemingly Too Fine for Human Discernment.*—As in ants, so in bees, Sir John [Lubbock's] experiments failed to yield any evidence of a sense of hearing. But in this connection we must not forget the well-known fact, first observed by Huber, that the queen bee will answer by a certain sound the peculiar piping of a pupa queen; and again, by making a certain cry or humming noise, will strike consternation suddenly on all the bees in the hive—these remaining for a long time motionless as if stupefied.—ROMANES *Animal Intelligence*, ch. 4, p. 144. (A., 1899.)

1450. HEARTH AS TYPE OF HOME—*Wood as Fuel—Exhaustion of—The Indian's Guess.*—When in the savage hut the logs are piled on the earthen floor, this simple hearth already becomes the gathering-place of the family and the type of home. But in treeless districts the want of fuel is one of the difficulties of life, as where on the desert plains the buffalo-hunter has to pick up for the evening fire the droppings which he calls "buffalo-chips" or *bois de vache*. Even in woodland countries, as soon as people collect in villages, the fire-wood near by is apt to run short. When some American Indians were asked what reason they supposed had brought the white men to their country, they answered quite simply that no doubt we had burnt up all our wood at home and had to move. The guess was so far good that something of the kind must really have happened had we depended on the fuel from our forests and peat-bogs, for the supply in England was giving out.—TYLOR *Anthropology*, ch. 11, p. 270. (A., 1899.)

1451. HEAT A MODE OF MOTION—*Recent Theory Foreshadowed.*—By this corpuscular or mechanical philosophy Boyle [1626-1692] explains such things as he regards as natural phenomena—such as heat and cold, tastes, corrosiveness, fixedness, volatility, chemical precipitation, and, finally, magnetism and electricity. Thus, heat, he says, is "that mechanical affection of matter we call local motion, mechanically modified" in three ways: first, by the vehement agitation of the parts; second, that the motions be very various in direction; and third, that the agitated particles, or at least the greatest number of them, be so minute as to be singly insensible.

It is singular how the mechanical theory —or, as we now term it, the dynamical theory, as applied to heat—impressed itself upon the philosophers of the seventeenth century. Bacon defines heat as "a motion acting in its strife upon the smaller particles of bodies." Boyle saw clearly that when heat is generated by mechanical means new heat is called into existence, and believed that the production of heat and electricity were somehow correlated. Locke, in his "Essay on the Human Understanding," says that "what in our sensation is heat, in the object is nothing but motion." Hooke plainly perceived heat as a vibration, and denies the existence of anything without motion, and hence perfectly cold. Yet it was the material and not the mechanical theory which prevailed and which held the beliefs of the world up to our own time.—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 13, p. 416. (J. W., 1898.)

1452. ——— ——— *The Atomic Theory in Chemistry.*—As long as distance separates [atoms or molecules] they can move across it in obedience to the attraction; and the motion thus produced may, by proper appliances, be caused to perform mechanical work. When, for example, two atoms of hydrogen unite with one of oxygen, to form water, the atoms are first drawn towards each other—they move, they clash, and then, by virtue of their resiliency, they recoil and quiver. To this quivering motion we give the name of heat. This atomic vibration is merely the redistribution of the motion produced by the chemical affinity; and this is the only sense in which chemical affinity can be said to be converted into heat. We must not imagine the chemical attraction destroyed or converted into anything else. For the atoms, when mutually clasped to form a molecule of water, are held together by the very attraction which first drew them towards each other. That which has really been expended is the pull exerted through the space by which the distance between the atoms has been diminished.—TYNDALL *Fragments of Science*, vol. i, ch. 1, p. 25. (A., 1897.)

1453. HEAT AND ELECTRICITY—*Electric Conduction Increased by Cold—Atomic Theory of Electricity.*—If we make a comparison of electric conductors we find that the metals that conduct heat best also conduct electricity best. This, it seems to me, is a confirmation of the atomic theory of electricity so far as it means anything. If a good conductor, as silver, is subjected to intense cold by putting it into liquid air, its conductivity is greatly increased. It is well known that heating a conductor ordinarily diminishes its power to conduct electricity. This shows that, in order that electrical motion of the atom may have free play, the heat motion must be suppressed.—ELISHA GRAY *Nature's Miracles*, vol. iii, ch. 5, p. 47. (F. H. & H., 1900.)

1454. HEAT A RESULT OF MOTION—*Water of Cataract Warmed by the Fall—Ocean Made Warmer by Storm.*—This small basin contains a quantity of mercury which has been cooled in the next room. One of the faces of the thermo-electric pile is plunged into the liquid metal. The deflection of the needle proves that the mercury is cold. Two glasses are swathed thickly round with listing, to prevent the warmth of the hands from reaching the mercury. I pour the cold mercury into one of the glasses, and then from the one glass into the other, and back Its motion is destroyed, but heat is developed. The amount of heat generated by a single pouring out is extremely small: so we will repeat the process ten or fifteen times. The pile being now plunged into the liquid, the needle moves; and its motion declares that the mercury, which at the beginning of the experiment was cooler, is now warmer than the pile. We here introduce into the lecture-room an effect which occurs at the base of every waterfall. There are friends before me who have stood amid the foam of Niagara, and I have done so myself. Had we dipped sufficiently sensitive thermometers into the water at the top and at the bottom of the cataract, we should have found the latter warmer than the former. The sailor's tradition, also, is theoretically correct; the sea is rendered warmer by a storm, the mechanical dash of its billows being ultimately converted into heat.—TYNDALL *Heat a Mode of Motion*, lect. 1, p. 6. (A., 1900.)

1455. HEAT DEVELOPED BY CHEMISTRY AND ELECTRICITY—It has already been stated that chemical changes develop electricity; which, in its turn, becomes a powerful disturbing cause. As a chemical agent, says Davy, its silent and slow operation in the economy of Nature is much more important than its grand and impressive operation in lightning and thunder. It may be considered not only as directly producing an infinite variety of changes, but as influencing almost all which take place; it would seem, indeed, that chemical attraction itself is only a peculiar form of the exhibition of electrical attraction.—LYELL *Principles of Geology*, bk. ii, ch. 31, p. 542. (A., 1854.)

1456. HEAT, FRICTION AN INEXHAUSTIBLE SOURCE OF—*Count Rumford's Argument.*—With Rumford, however, a new and powerful factor appeared on the scene. He began by proving the hypothetical matter of heat to be imponderable, but the main drift of his experiments was to prove friction to be an inexhaustible source of heat, while the whole force of his logic went to show that an inexhaustible emission is irreconcilable with the notion that heat is a kind of matter.—TYNDALL *Heat a Mode of Motion*, lect. 2, p. 39. (A., 1900.)

1457. HEAT OF EARTH, LOSS OF—*No Sensible Diminution in Two Thousand Years.*—The gradual diminution of the supposed primitive heat of the globe has been resorted to by many geologists as the principal cause of alterations of climate. The matter of our planet is imagined, in accordance with the conjectures of Leibnitz, to have been originally in an intensely heated state, and to have been parting ever since with portions of its heat, and at the same time contracting its dimensions. There are, undoubtedly, good grounds for inferring from recent observation and experiment that the temperature of the earth increases as we descend from the surface to that slight depth to which man can penetrate: but there are no positive proofs of a secular decrease of internal heat accompanied by contraction. On the contrary, Laplace has shown, by reference to astronomical observations made in the time of Hipparchus, that in the last two thousand years at least there has been no sensible contraction of the globe by cooling; for had this been the case, even to an extremely small amount, the day

would have been shortened, whereas its length has certainly not diminished during that period by $\frac{1}{100}$th of a second.—LYELL *Principles of Geology*, bk. i, ch. 8, p. 129. (A., 1854.)

1458. HEAT OF HUMAN BODY—*Energy Expended in Maintaining—Other Expenditures of Energy.*—The amount of energy daily manifested by the adult human body in (a) the maintenance of its temperature; (b) in internal mechanical work, as in the movements of the respiratory muscles, the heart, etc.; and (c) in external mechanical work, as in locomotion and all other voluntary movements, has been reckoned at about 3,400 foot-tons. Of this amount only one-tenth is directly expended in internal and external mechanical work, the remainder being employed in the maintenance of the body's heat. The latter amount represents the heat which would be required to raise 48.4 lbs. of water from the freezing- to the boiling-point; or, if converted into mechanical power, it would suffice to raise the body of a man weighing about 150 lbs. through a vertical height of 8½ miles.

To the foregoing amounts of expenditure must be added the quite unknown quantity expended in the various manifestations of nerve-force, and in the work of nutrition and growth (using these terms in their widest sense). By comparing the amount of energy which should be produced in the body, from so much food of a given kind, with that which is actually manifested (as shown by the various products of combustion in the excretions), attempts have been made, indeed, to estimate, by a process of exclusion, these unknown quantities; but all such calculations must be at present considered only very doubtfully approximate.—BAKER *Handbook of Physiology*, vol. ii, ch. 17, p. 65. (W. W., 1885.)

1459. ——— *Loss of, in Exercise—Exertion Creates New Supply.*—It would appear . . . that the body ought to grow colder, in the act of climbing or of working [since heat is thrown off from the body into space], whereas universal experience proves it to grow warmer. The solution of this seeming contradiction is found in the fact that, when the muscles are exerted, augmented respiration and increased chemical action set in. The fan which urges oxygen into the fire within is more briskly moved; and thus, tho heat actually disappears as we climb, the loss is more than covered by the increased activity of the chemical processes.—TYNDALL *Heat a Mode of Motion*, lect. 17, p. 531. (A., 1900.)

1460. ——— *Loss of, through Inanition—Death by Starvation Is Death by Cold—External Warmth in Exhaustive Diseases.*—It has been often said, and with truth, altho the statement requires some qualification, that death by starvation is really death by cold: for not only has it been found that differences of time with regard to the period of the fatal result are attended by the same ultimate loss of heat [about 30° F.], but the . . . application of external warmth to animals cold and dying from starvation is [found to be] more effectual in reviving them than the administration of food. In other words, an animal exhausted by deprivation of nourishment is unable so to digest food as to use it as fuel, and therefore is dependent for heat on its supply from without. Similar facts are often observed in the treatment of exhaustive diseases in man.—BAKER *Handbook of Physiology*, vol. i, ch. 7, p. 220. (W. W., 1885.)

1461. HEAT OF THE ATMOSPHERE—*Chill of Upper Air—Absolute Zero of Space.*—If we suddenly compress a cubic foot of air at ordinary pressure into a cubic inch of space, that cubic inch will be very hot because it contains all the heat that was distributed through the entire cubic foot before the compression took place. Now let it remain compressed until the heat has radiated from it, as it soon will, and the air becomes of the same temperature as the surrounding air. What ought to happen if then we should suddenly allow this cubic inch of air to expand to its normal pressure, when it will occupy a cubic foot of space? Inasmuch as we allowed the heat to escape from it when in the condensed form, when it expands it will be very cold, because the heat of the cubic inch, now reduced to the normal temperature of the surrounding air, is distributed over a cubic foot of space. This is precisely what takes place when heated air at the surface of the earth (which is condensed to a certain extent) rises to the higher regions of the atmosphere. There is a gradual expansion as it ascends, and consequently a gradual cooling, because a given amount of heat is being constantly distributed over a greater amount of space. At an altitude of forty-five miles it will have expanded about 25,000 times, which will bring the temperature down to between 200 and 300 degrees below zero. When we get beyond the limits of the atmosphere we get into the region of absolute cold, because heat is atomic motion, and there can be no atomic motion where there are no atoms.—ELISHA GRAY *Nature's Miracles*, vol. i, ch. 7, p. 54. (F. H. & H., 1900.)

1462. HEAT, PLANTS NEED UNIFORM—*Light May Vary More.*—There is every reason to conclude that the range of intensity of light to which living plants can accommodate themselves is far wider than that of heat. No palms or tree-ferns can live in our temperate latitudes without protection from the cold: but when placed in hothouses they grow luxuriantly, even under a cloudy sky, and where much light is intercepted by the glass and frame-work. At St. Petersburg, in lat. 60° N., these plants have been successfully cultivated in

hothouses, altho there they must exchange the perpetual equinox of their native regions for days and nights which are alternately protracted to nineteen hours and shortened to five. How much farther towards the pole they might continue to live, provided a due quantity of heat and moisture were supplied, has not yet been determined; but St. Petersburg is probably not the utmost limit, and we should expect that in lat. 65° at least, where they would never remain twenty-four hours without enjoying the sun's light, they might still exist.—LYELL *Principles of Geology*, bk. i, ch. 6, p. 89. (A., 1854.)

1463. HEAT PRODUCING COLD—*Refrigeration Improves Food of Nations.*—Since heat is transformable into motive power, and motive power can force ammonia to chill itself, a ton of coal, according to quality, can make six to ten tons of ice in competition with the frosts of winter. Because their product is pure, refrigerating-machines are finding more and more favor in cities once supplied exclusively with ice from ponds and streams. . . . Cold, so singular an issue of heat, has high commercial value. Apples and grapes harvested in September and October are sent from the cold-storage warehouse to the table in perfect order as late as May. The fruit-grower and the dairyman have a new opportunity to choose the time for marketing their products. Refrigerator steamships now carry Canadian butter and New Zealand meat in vast quantities to the markets of Great Britain. Within the shorter distances traversed by the railroads of the United States the strawberries of Oregon find their way unbruised and fresh to St. Paul and Chicago, while the kitchen-gardeners of Florida and Louisiana look for their customers in New England and New York. There is more in all this than the mere purveying of luxuries; there is an increase of individual health and strength when a national bill of fare is at once diversified and made more wholesome. Whereas heat in the hands of early man served to multiply his foods by primitive methods of roasting, of smoking, of preservation in grease—as pemmican—the later applications of heat by the modern engineer are of incomparable service in multiplying the food-resources of the civilized world. Cold storage and quick transportation supplement in remarkable fashion every device that has sprung from the aboriginal grill and kettle.—ILES *Flame, Electricity, and the Camera*, ch. 5, p. 66. (D. & McC., 1900.)

1464. HEAT PROVED NOT A SUBSTANCE—*Thermal Vibration Compared to Sound of Bell.*—With regard to the illustration which compared heat to water contained in a sponge, Rumford replied thus: "A sponge filled with water and hung by a thread in the middle of a room filled with dry air communicates its moisture to the air, it is true, but soon the water evaporates and the sponge can no longer give out moisture." The case, he contended, is not at all similar to heat; for here, by renewed mechanical action, we can cause the heat to flow out at will. "A bell," he says, "sounds without intermission when it is struck, and gives out its sound as often as we please, without any perceptible loss. Moisture is a substance, sound is not." Heat, he contended, was typified by the vibrating bell and not by the evaporating sponge.—TYNDALL *Heat a Mode of Motion*, lect. 2, p. 46. (A., 1900.)

1465. HEAT, SUPPLY OF, WITHIN THE EARTH—*Science May Yet Mine for Heat—A City Receives Hot Water from Underground.*—So marked is this steady increase of temperature as we go downwards, that it has been seriously proposed to make very deep borings in order to obtain supplies of warm water for heating our towns. Arago and Walferdin suggested this method for warming the Jardin des Plantes at Paris; and now that such important improvements have been devised in carrying borings to enormous depths, the time may not be far distant when we shall draw extensively upon these supplies of subterranean heat. At the present time the city of Budapest is extensively supplied with hot water from an underground source. Should our coal-supply ever fail, it may be well to remember that we have these inexhaustible supplies of heat everywhere beneath our feet.—JUDD *Volcanoes*, ch. 12, p. 335. (A., 1899.)

1466. HEAT SUPPOSED TO BE MATTER—*Phlogiston—Count Rumford's Experiment—Heat Proved To Be Motion—Errors of Early Scientists.*—Down to the beginning of this century heat was generally considered to be a form of matter, termed caloric or phlogiston. The presence of phlogiston was supposed to render substances combustible, but when the chemical theory of combustion was discovered by Lavoisier, phlogiston, as the cause of combustion, disappeared, altho caloric, as the material basis of heat, still held its ground. Close to the end of the last century Count Rumford showed that in boring a brass cannon the heat developed in 2½ hours was sufficient to raise 26½ lbs. of water from the freezing- to the boiling-point. But during the operation the metal had lost no weight nor undergone any other change; and as the production of heat by this process appeared to be unlimited he concluded that heat could not be matter, but merely a kind of motion set up in the particles of matter by the force exerted. . . . Such facts led to the conclusion that there was a mechanical equivalent of heat—that is, that a certain amount of force exerted or work done would produce a corresponding amount of heat; and Joule was the first to determine this accurately by a number of ingenious experiments. The result was found to be that a pound of water can be raised 1° C. by an amount of work equal

to that required to raise one pound to the height of 1,392 feet, or 1,392 lbs. one foot. Various experiments with different materials were found always to lead to the same result, and thus the final blow was given to the material theory of heat, which was thenceforth held to be a mode of motion of the molecules of bodies.—WALLACE *The Wonderful Century*, ch. 7, p. 51. (D. M. & Co., 1899.)

1467. HEAT TRANSFORMED INTO FORCE, AND FORCE AGAIN INTO HEAT—The doctrine of heat as due to vibration explains how heat is transformed force, so that the steam-hammer worked by the heat used in the furnace can be set to beat cold iron till it is white-hot; thus part of the force which came from heat has gone back into heat, and with the heat reappears the other form of radiant energy, light.—TYLOR *Anthropology*, ch. 13, p. 327. (A., 1899.)

1468. HEAT TRANSFORMED INTO MOTION, AND VICE VERSA—We derive the muscle and fat of our bodies from what we eat. Animal heat you know to be due to the slow combustion of this fuel. My arm is now inactive, and the ordinary slow combustion of my blood and tissue is going on. For every grain of fuel thus burnt a perfectly definite amount of heat has been produced. I now contract my biceps muscle without causing it to perform external work. The combustion is quickened and the heat is increased, this additional heat being liberated in the muscle itself. I lay hold of a 56-lb. weight, and by the contraction of my biceps lift it through the vertical space of a foot. The blood and tissue consumed during this contraction have not developed in the muscle their due amount of heat. A quantity of heat is at this moment missing in the muscle which would raise the temperature of an ounce of water somewhat more than 1° F. I liberate the weight; it falls to the earth, and by its collision generates the missing heat. Muscular heat is thus transferred from its local hearth to external space. The fuel is consumed in the body, but the heat of combustion is produced outside the body. The case is substantially the same as that of the voltaic battery when it performs external work or produces external heat.—TYNDALL *Heat a Mode of Motion*, lect. 3, p. 83. (A., 1900.)

1469. HEIGHTS ATTAINED BY INSECTS—*Butterflies on Mont Blanc—Flies on Chimborazo.*—Saussure found butterflies on Mont Blanc, and Ramond observed them in the solitudes around the summit of Mont Perdu. When MM. Bonpland, Carlos Montufar, and myself, on the 23d of June, 1802, ascended the eastern declivity of Mount Chimborazo, to a height of 19,286 feet, and where the barometer had fallen to 14.84 inches, we found winged insects buzzing around us. We recognized them to be *Diptera*, resembling flies, but it was impossible to catch these insects standing on the rocky ledges *(cuchilla)*, often less than a foot in breadth, and between masses of snow precipitated from above. The elevation at which we observed these insects was almost the same as that in which the naked trachytic rock, which projected from the eternal snows around, exhibited the last traces of vegetation in *Lecidea geographica.* These insects were flying at an elevation of 18,225 feet, or nearly 2,660 feet higher than the summit of Mont Blanc; and somewhat below this height, at an elevation of 16,626 feet, and therefore also above the region of snow, M. Bonpland saw yellow butterflies flying close to the ground.—HUMBOLDT *Views of Nature*, p. 232. (Bell, 1896.)

1470. HELP TO THE NEEDY—*Good Samaritan in the Ant World.*—One day, watching a small column of these ants *(i. e., Eciton hamata)*, I placed a little stone on one of them to secure it. The next that approached, as soon as it discovered its situation, ran backwards in an agitated manner, and soon communicated the intelligence to the others. They rushed to the rescue; some bit at the stone and tried to move it, others seized the prisoner by the legs and tugged with such force that I thought the legs would be pulled off, but they persevered until they got the captive free. I next covered one up with a piece of clay, leaving only the ends of its antennæ projecting. It was soon discovered by its fellows, which set to work immediately, and by biting off pieces of the clay soon liberated it. Another time I found a very few of them passing along at intervals. I confined one of these under a piece of clay at a little distance from the line, with his head projecting. Several ants passed it, but at last one discovered it and tried to pull it out, but could not. It immediately set off at a great rate, and I thought it had deserted its comrade, but it had only gone for assistance, for in a short time about a dozen ants came hurrying up, evidently fully informed of the circumstances of the case, for they made directly for their imprisoned comrade and soon set him free. I do not see how this action could be instinctive. It was sympathetic help, such as man only among the higher mammalia shows. The excitement and ardor with which they carried on their unflagging exertions for the rescue of their comrade could not have been greater if they had been human beings.—ROMANES *Animal Intelligence*, ch. 3, p. 47. (A., 1899.)

1471. HELPLESS DESTROYED BY STRONG—*The Herd Gores the Disabled Cow to Death.*—It remains now to speak of that seemingly most cruel of instincts [that leads a herd to kill the injured]. It is very common among gregarious animals that are at all combative in disposition, and still survives in our domestic cattle, altho very rarely witnessed in England. My first experience of it was just before I had reached the

age of five years. I was not at that early period trying to find out any of Nature's secrets. but the scene I witnessed printed itself vividly on my mind, so that I can recall it as well as if my years had been five-and-twenty; perhaps better. It was on a summer's evening, and I was out by myself at some distance from the house, playing about the high exposed roots of some old trees; on the other side of the trees the cattle, just returned from pasture, were gathered on the bare level ground. Hearing a great commotion among them, I climbed on to one of the high exposed roots, and looking over saw a cow on the ground, apparently unable to rise, moaning and bellowing in a distressed way, while a number of her companions were crowding round and goring her. [Interpreted by Romanes and others as a protection of the herd against being followed by beasts of prey; by Hudson as a frenzy of instinct misdirected.]—HUDSON *Naturalist in La Plata*, ch. 22, p. 339. (C. & H., 1895.)

1472. HELPLESSNESS A SOURCE OF POWER—*Prolongation of Infancy Accompanied by Increase of Brain-surface—Gulf between Man and Ape.*—The gulf by which the lowest known man is separated from the highest known ape consists in the great increase of his cerebral surface, with the accompanying intelligence, and in the very long duration of his infancy. These two things have gone hand in hand. The increase of cerebral surface, due to the working of natural selection in this direction alone, has entailed a vast increase in the amount of cerebral organization that must be left to be completed after birth, and thus has prolonged the period of infancy. And, conversely, the prolonging of the plastic period of infancy, entailing a vast increase in teachableness and versatility, has contributed to the further enlargement of the cerebral surface.—FISKE *Destiny of Man*, ch. 6, p. 54. (H. M. & Co., 1900.)

1473. HELPLESSNESS OF HUMAN BABE—*Contrast with Baby Monkey—Bodily Development Retarded by the Demands of the Finer Brain—This Trains Motherhood.*—In a few days or weeks the baby monkey is almost able to leave its mother. Already it can climb and eat and chatter like its parents, and in a few weeks more the creature is as independent of them as the winged seed is of the parent tree. Meantime, and for many months to come, its little twin is unable to feed itself, or clothe itself, or protect itself; it is a mere semi-unconscious chattel, a sprawling ball of helplessness, the world's one type of impotence. The body is there in all its parts, bone for bone and muscle for muscle, like the other. But somehow this body will not do its work. Something as yet hangs fire. The body has eyes, but they see not; ears, but they hear not; limbs, but they walk not. This body is a failure. Why does the human infant lie like a log on the forest-bed while its nimble prototype mocks it from the bough above? . . . It was necessary for moral training that the human child should have the longest possible time by its mother's side—but what determines it on the physical side? The thing that constitutes the difference between the baby monkey and the baby man is an extra piece of machinery which the last possesses and the first does not. It is this which is keeping back the baby man. What is that piece of machinery? A brain, a human brain. The child, nevertheless, is not using it. Why? Because it is not quite fitted up. Nature is working hard at it; but owing to its intricacy and delicacy the process requires much time, and till all is ready the babe must remain a thing. And why does the monkey brain get ready first? Because it is an easier machine to make. And why should it be easier to make? Because it is only required to do the life-work of an animal; the other has to do the life-work of a man.—DRUMMOND *Ascent of Man*, ch. 8, p. 282. (J. P., 1900.)

1474. ——— ——— *Prolonged Infancy Gives Time to Elaborate the Brain—Childhood a Time of Installations and Trials.*—Now infancy, physiologically considered, means the fitting up of this extra machinery within the brain; and according to its elaborateness will be the time required to perfect it. A sailing-vessel may put to sea the moment the rigging is in; a steamer must wait for the engines. And the compensation to the steamer for the longer time in dock is discovered by and by in its vastly greater usefulness, its power of varying its course at will, and in its superior safety in time of war or storm. For its greater afterusefulness also, its more varied career, its safer life, humanity has to pay tribute to evolution by a delayed and helpless infancy, a prolonged and critical constructive process. Childhood in its early stage is a series of installations and trials of the new machinery, a slow experimenting with powers and faculties so fresh that heredity in handing them down has been unable to accompany them with full directions as to their use.—DRUMMOND *Ascent of Man*, ch. 8, p. 285. (J. P., 1900.)

1475. HELPLESSNESS RESULTING FROM INDOLENCE—*Slaveholding Ants Forget How To Feed Themselves.*—In consequence of being constantly fed by their slaves, the red ants have entirely forgotten how to procure food for themselves. If they are shut up and supplied with honey, which is their favorite food, they will not touch it, but will suffer hunger, become weak and feeble, and ultimately, die of starvation, unless pity is taken upon them and they are given one of their dusky slaves. Directly this is done the slave falls to work, eats a quantity of the honey, and then proceeds to feed its masters, which are per-

fectly willing to be saved from starvation in this manner.—WEISMANN *Heredity*, vol. ii, ch. 9, p. 26. (Cl. P., 1897.)

1476. HEMISPHERES OF BRAIN CONTROL OPPOSITE SIDE OF BODY—Electrical currents of small intensity applied to the surface of the said convolutions [of the brain] in dogs, monkeys, and other animals produce well-defined movements in face, fore-limb, hind-limb, tail, or trunk, according as one point or another of the surface is irritated. These movements affect almost invariably the side opposite to the brain irritations: If the left hemisphere be excited the movement is of the right leg, side of face, etc.—JAMES *Psychology*, vol. i, ch. 2, p. 31. (H. H. & Co., 1899.)

1477. HERCULANEUM BURIED IN LAVA—*Nearer than Pompeii to the Volcano—Cast of Buried Mask—Ancient Buildings Enclosed in Rock.*—It was remarked that no lava has flowed over the site of Pompeii since that city was built, but with Herculaneum the case is different. Altho the substance which fills the interior of the houses and the vaults must have been introduced in a state of mud, like that found in similar situations in Pompeii, yet the superincumbent mass differs wholly in composition and thickness. Herculaneum was situated several miles nearer to the volcano, and has, therefore, been always more exposed to be covered, not only by showers of ashes, but by alluviums and streams of lava. Accordingly, masses of both have accumulated on each other above the city to a depth of nowhere less than 70, and in many places of 112 feet.

The tuff which envelops the buildings consists of comminuted volcanic ashes, mixed with pumice. A mask embedded in this matrix has left a cast, the sharpness of which was compared by Hamilton to those in plaster of Paris; nor was the mask in the least degree scorched, as if it had been embedded in heated matter. This tuff is porous; and, when first excavated, is soft and easily worked, but acquires a considerable degree of induration on exposure to the air.—LYELL *Principles of Geology*, bk. ii, ch. 24, p. 389. (A., 1854.)

1478. HERCULANEUM, RELICS IN—*Remarkable Preservation of Ancient Objects—Perishable Goods Remaining of Owners Who Vanished Centuries Ago.*—The wooden beams in the houses at Herculaneum are black on the exterior, but, when cleft open, they appear to be almost in the state of ordinary wood, and the progress made by the whole mass towards the state of lignite is scarcely appreciable. Some animal and vegetable substances of more perishable kinds have, of course, suffered much change and decay, yet the state of preservation of these is truly remarkable. Fishing-nets are very abundant in both cities, often quite entire; and their number at Pompeii is the more interesting from the sea being now, as we stated, a mile distant. Linen has been found at Herculaneum, with the texture well defined; and in a fruiterer's shop in that city were discovered vessels full of almonds, chestnuts, walnuts, and fruit of the "carubiere," all distinctly recognizable from their shape. A loaf, also, still retaining its form, was found in a baker's shop, with his name stamped upon it. On the counter of an apothecary was a box of pills converted into a fine earthy substance, and by the side of it a small cylindrical roll evidently prepared to be cut into pills. By the side of these was a jar containing medicinal herbs. In 1827, moist olives were found in a square glass case, and "caviare," or roe of a fish, in a state of wonderful preservation. An examination of these curious condiments has been published by Covelli, of Naples, and they are preserved hermetically sealed in the museum there.—LYELL *Principles of Geology*, bk. ii, ch. 24, p. 392. (A., 1854.)

1479. HEREDITY, ALCOHOLIC—*Statistics of Idiocy and Insanity.*—There is one class of cases, moreover, in which a particular abnormal form of nutrition that is distinctly acquired by the individual exerts a most injurious influence upon the offspring—that, namely, which is the result of such habitual alcoholic excess as modifies the nutrition of the nervous system.

We have a far larger experience of the results of habitual alcoholic excess than we have in regard to any other "nervine stimulant": and all such experience is decidedly in favor of the hereditary transmission of that acquired perversion of the normal nutrition which it has engendered in the individual. That this manifests itself sometimes in congenital idiocy, sometimes in a predisposition to insanity, which requires but a very slight exciting cause to develop it, and sometimes in a strong craving for alcoholic drinks, which the unhappy subject of it strives in vain to resist, is the concurrent testimony of all who have directed their attention to the inquiry. Thus Dr. Howe, in his report on the statistics of idiocy in Massachusetts, states that the habits of the parents of 300 idiots having been learned, 145, or nearly one-half, were found to be habitual drunkards. In one instance, in which both parents were drunkards, seven idiotic children were born to them. Dr. Down, whose experience of idiocy is greater than that of any other man in this country, has assured the writer that he does not consider Dr. Howe's statement as at all exaggerated. Dr. W. A. F. Browne, the first Medical Lunacy Commissioner for Scotland, thus wrote when himself in charge of a large asylum: "The drunkard not only injures and enfeebles his own nervous system, but entails mental disease upon his family. His daughters are nervous and hysterical; his sons are weak, wayward, eccentric, and sink under the pressure of excitement of some unforeseen exigency, or the ordinary calls of duty." Dr. Howe remarks

that the children of drunkards are deficient in bodily and vital energy, and are predisposed by their very organization to have cravings for alcoholic stimulants. If they pursue the course of their fathers, which they have more temptation to follow, and less power to avoid, than the children of the temperate, they add to their hereditary weakness, and increase the tendency to idiocy or insanity in their constitution, and this they leave to their children after them. [See ALCOHOL.]—CARPENTER *Mental Physiology*, ch. 8, p. 370. (A., 1900.)

1480. HEREDITY AND ENVIRONMENT —*Master-influences of Life.*—These two, heredity and environment, are the master-influences of the organic world. These have made all of us what we are. These forces are still ceaselessly playing upon all our lives. And he who truly understands these influences; he who has decided how much to allow to each; he who can regulate new forces as they arise, or adjust them to the old, so directing them as at one moment to make them cooperate, at another to counteract one another, understands the rationale of personal development. To seize continuously the opportunity of more and more perfect adjustment to better and higher conditions, to balance some inward evil with some purer influence acting from without, in a word to make our environment at the same time that it is making us—these are the secrets of a well-ordered and successful life. —DRUMMOND *Natural Law in the Spiritual World*, essay 7, p. 229. (H. M.)

1481. HEREDITY EVERYTHING IN LOWEST TYPE OF ANIMAL—*Starts with Nothing To Learn.*—The psychical life of the lowest animals consists of a few simple acts directed toward the securing of food and the avoidance of danger, and these acts we are in the habit of classing as instinctive. They are so simple, so few, and so often repeated that the tendency to perform them is completely organized in the nervous system before birth. The animal takes care of himself as soon as he begins to live. He has nothing to learn, and his career is a simple repetition of the careers of countless ancestors. With him heredity is everything, and his individual experience is next to nothing.—FISKE *Destiny of Man*, ch. 4, p. 39. (H. M. & Co., 1900.)

1482. HEREDITY IN ASTRONOMIC RESEARCH—*The Younger Carries on the Researches of the Elder Herschel.*—In his special line as a celestial explorer of the most comprehensive type, Sir William Herschel had but one legitimate successor, and that successor was his son. John Frederick William Herschel was born at Slough, March 17, 1792, graduated with the highest honors from St. John's College, Cambridge, in 1813, and entered upon legal studies with a view to being called to the bar. But his share in an early compact with Peacock and Babbage, "to do their best to leave the world wiser than they found it," was not thus to be fulfilled. The acquaintance of Dr. Wollaston decided his scientific vocation. . . .

The full results of [Sir John] Herschel's journey to the Cape were not made public until 1847, when a splendid volume embodying them was brought out at the expense of the Duke of Northumberland. They form a sequel to his father's labors such as the investigations of one man have rarely received from those of another. What the elder observer did for the northern heavens, the younger did for the southern.—CLERKE *History of Astronomy*, pt. i, ch. 2, pp. 54, 56. (Bl., 1893.)

1483. HEREDITY MAY TRANSMIT PREDISPOSITION TO DISEASE—*Environment a Predisposing Cause.*—We know from experience that a full measure of health is not often the happy condition of human tissues; we have, in short, a variety of circumstances which, as we say, predispose the individual to disease. One of the commonest forms of predisposition is that due to heredity. Probably it is true that what are known as hereditary diseases are due far more to a hereditary predisposition than to any transmission of the virus itself in any form. Antecedent disease predisposes the tissues to form a nidus for bacteria; conditions of environment or personal habits frequently act in the same way. Damp soils must be held responsible for many disasters to health, not directly, but indirectly, by predisposition; dusty trades and injurious occupations have a similar effect. Any one of these three different influences may in a variety of ways affect the tissues and increase their susceptibility to disease. Not infrequently we may get them combined.—NEWMAN *Bacteria*, ch. 8, p. 268. (G. P. P., 1899.)

1484. HEREDITY OF ACQUIRED CHARACTERS -*Cope's Advocacy of the Doctrine.*—Cope early adopted the doctrine of transmutation of species, and recognized the truth that all the animals of the present epoch are descendants from those of past times, with modifications which separate them as species, and eventually as representatives of genera, of families and orders differing from the earlier ones as we retrace the steps of time farther and farther back. He was not, however, satisfied with Darwin's theory, and denied that natural selection was a sufficient factor for differentiation. He would not admit that animals were passive subjects and that the slight variations which were manifest in the progeny of species were sufficient to enable Nature to select from and to fit for future conditions. He contended that the volition and endeavors of an animal had much to do with future progeny as well as its own brief life. In short, he claimed that characters acquired by animals through their own efforts, or forced on them by vari-

ous external agencies or accidents, might be transmitted to their offspring. [See DEVIATIONS INHERITABLE.] — GILL *Address in Memory of Edward Drinker Cope* in *Proceedings of Amer. Assoc. for Advancement of Science*, vol. xlvi, 1897.

1485. ——— ——— *Epileptic Guinea-pigs.*—A very curious example of the transmission of tendencies to special automatic movements, the secondary acquirement of which tendencies is altogether beyond doubt, is afforded by the following curious fact established by the researches of M. Brown-Séquard: In the course of his masterly experimental investigations on the functions of the nervous system, he discovered that, after a particular lesion of the spinal cord of guinea-pigs, a slight pinching of the skin of the face would throw the animals into a kind of epileptic convulsion. That this artificial epilepsy should be constantly producible in guinea-pigs, and not in any other animals experimented upon, was in itself sufficiently singular; and it was not less surprising that the tendency to it persisted, after the lesion of the spinal cord seemed to have been entirely recovered from. But it was far more wonderful that when these epileptic guinea-pigs bred together, their offspring showed the same predisposition, without having been themselves subjected to any lesion whatever; whilst no such tendency showed itself in any of the large number of young, which were bred by the same accurate observer from parents that had not thus been operated on.—CARPENTER *Mental Physiology*, ch. 8, p. 371. (A., 1900.)

1486. ——— ——— *How Limited.*—In [many] exercises of [animal] intelligence we may trace the manifestations of a hereditary transmission of aptitudes for particular kinds of mental action which have been originally acquired by habit. Dogs of other breeds cannot be taught to herd sheep in the manner which "comes naturally" to the young of the shepherd's dog. And it is well known that young pointers and retrievers, when first taken into the field, will often "work" as well as if they had been long trained to the requirements of the sportsman. The curious fact was observed by Mr. Knight that the young of a breed of springing spaniels which had been trained for several successive generations to find woodcocks, seemed to know as well as the old dogs what degree of frost would drive the birds to seek their food in unfrozen springs and rills. Among the descendants of the dogs originally introduced into South America by the Spaniards there are breeds which have learned by their own experience, without any human training, the best modes of attacking the wild animals they pursue; and since young dogs have been observed to practise these methods the very first time they engage in the chase, with as much address as old dogs, it can scarcely be questioned that the tendency to the performance of them has been embodied in the organization of the race, and is thus transmitted hereditarily. There seems reason to believe that such hereditary transmission is limited to acquired peculiarities which are simply modifications of the natural constitution of the race, and would not extend to such as may be altogether foreign to it. But the foregoing facts would seem to justify the belief that the like hereditary transmission of acquired aptitudes may take place in man; and that, in accordance with the far wider range of his faculties, it may become the means of a far higher exaltation of them.—CARPENTER *Mental Physiology*, ch. 2, p. 102. (A., 1900.)

1487. ——— ——— *Inherited Effect of Changed Habits.*—Changed habits produce an inherited effect, as in the period of the flowering of plants when transported from one climate to another. With animals the increased use or disuse of parts has had a more marked influence; thus I find in the domestic duck that the bones of the wing weigh less and the bones of the leg more, in proportion to the whole skeleton, than do the same bones in the wild duck; and this change may be safely attributed to the domestic duck flying much less, and walking more, than its wild parents. [See INHERITANCE.]—DARWIN *Origin of Species*, ch. 1, p. 10. (Burt.)

1488. ——— ——— *Mental Habitudes Transmitted as Tendencies.*—Now, as there can be no doubt of the hereditary transmission in man of acquired constitutional peculiarities, which manifest themselves alike in tendencies to bodily and to mental disease, so it seems equally certain that acquired mental habitudes often impress themselves on his organization with sufficient force and permanence to occasion their transmission to the offspring as tendencies to similar modes of thought. And thus, while all admit that knowledge cannot thus descend from one generation to another, an increased aptitude for the acquirement, either of knowledge generally, or of some particular kind of it, may be thus inherited. These tendencies and aptitudes will acquire additional strength, expansion, and permanence in each new generation, from their habitual exercise upon the materials supplied by a continually enlarged experience; and thus the acquired habitudes produced by the intellectual culture of ages will become a "second nature" to every one who inherits them.—CARPENTER *Nature and Man*, lect. 6, p. 197. (A., 1889.)

1489. ——— ——— *New Instincts the Result of Changed Circumstances.*—This explanation of the origin of the migratory instinct, and the reason why birds take certain determinate routes over the sea, is in perfect agreement with the conclusion at which Mr. Darwin arrived at an even earlier date, tho the facts were not pub-

lished until after his death. Instincts, he shows, can be acquired. Birds which were once perfectly fearless of man now display the usual terror, since the oceanic islands which they inhabit have been visited or settled, and transmit their prudent instinct to their offspring. On the other hand, while at first frightened by passing railway trains, they soon learn that these novelties betoken no danger, and so in time the birds alongside the lines view them with the most perfect equanimity. The sheep, which in Spain are taken every summer to pastures in another part of the country, acquire by and by an instinct for this artificial migration, which is displayed by curious uneasy motions, so strong that about the time when they ought to be off it requires all the vigilance of the shepherds to prevent them escaping, and there are cases in which the journey has been performed, the animals reaching their old feeding-grounds without assistance.—BROWN *Nature-Studies*, p. 21. (Hum., 1888.)

1490. ——— ——— *The Question Stated — Government and Philanthropy Involved.*—It is obvious that we can produce important changes in the individual. We can, for example, improve his muscles by athletics and his brain by education. The use of organs enlarges and strengthens them; the disuse of parts or faculties weakens them. And so great is the power of habit that it is proverbially spoken of as "second nature." It is thus certain that we can modify the individual. We can strengthen (or weaken) his body: we can improve (or deteriorate) his intellect, his habits, his morals. But there remains the still more important question which we are about to consider. Will such modifications be inherited by the offspring of the modified individual? Does individual improvement transmit itself to descendants independently of personal teaching and example? Have artificially produced changes of structure or habit any inherent tendency to become congenitally transmissible and to be converted in time into fixed traits of constitution or character? Can the philanthropist rely on such a tendency as a hopeful factor in the evolution of mankind? the only sound and stable basis of a higher and happier state of things being, as he knows or ought to know, the innate and constitutionally fixed improvement of the race as a whole. If acquired modifications are impressed on the offspring and on the race, the systematic moral training of individuals will in time produce a constitutionally moral race. . . . But if acquired modifications do not tend to be transmitted, if the use or disuse of organs or faculties does not similarly affect posterity by inheritance, then it is evident that no innate improvement in the race can take place without the aid of natural or artificial selection.—BALL *Are the Effects of Use and Disuse Inherited?* p. 7 (Hum., 1891.)

1491. ——— ——— *Views of Spencer and Mill—Brain-states Transmissible.*—This doctrine [of heredity of acquired characters] was first explicitly put forth by Mr. Herbert Spencer, in whose philosophical treatises it will be found most ably developed. I am glad to be able to append the following extract from a letter which Mr. John Mill, the great master of the experiential school, was good enough to write to me a few months since, with reference to the attempt I had made to place "common sense" upon this basis (*Contemporary Review*, February, 1872): "When states of mind in no respect innate or instinctive have been frequently repeated, the mind acquires, as is proved by the power of habit, a greatly increased facility of passing into those states; and this increased facility must be owing to some change of a physical character in the organic action of the brain. There is also considerable evidence that such acquired facilities of passing into certain modes of cerebral action can, in many cases, be transmitted, more or less completely, by inheritance. The limits of this power of transmission, and the conditions on which it depends, are a subject now fairly before the scientific world, and we shall doubtless in time know much more about them than we do now. But so far as my imperfect knowledge of the subject qualifies me to have an opinion, I take much the same view of it that you do, at least in principle."—CARPENTER *Nature and Man*, lect. 6, p. 197. (A., 1889.)

1492. HEREDITY OF AN IDIOT—*Four Steps from Immorality to Imbecility—Alcoholic Excess from the Outset.*—Morel has traced through four generations the family history of a youth who was admitted into the asylum at Rouen in a state of stupidity and semi-idiocy; the summary of which may fitly illustrate the natural course of degeneracy when it goes on through generations.

First generation: Immorality, depravity, alcoholic excess, and moral degradation, in the great-grandfather, who was killed in a tavern brawl.

Second generation: Hereditary drunkenness, maniacal attacks, ending in general paralysis, in the grandfather.

Third generation: Sobriety, but hypochondriacal tendencies, delusions of persecutions, and homicidal tendencies in the father.

Fourth generation: Defective intelligence. First attack of mania at sixteen; stupidity and transition to complete idiocy.—MAUDSLEY *Body and Mind*, lect. 2, p. 45. (A., 1898.)

1493. HEREDITY MOLDS CHARACTER—*Improvement and Adaptation.*—The setting-dog is taught to set; he squats down and points at the game; but the habit is an acquired one—a mere trick of education. What, however, is merely acquired habit in the progenitor is found to pass into instinct

n the descendant; the puppy of the setting-dog squats down and sets untaught—the educational trick of the parent is mysteriously transmuted into an original principle in the offspring. The adaptation which takes place in the forms and constitution of plants and animals when placed in circumstances different from their ordinary ones is equally striking. The woody plant of a warmer climate when transplanted into a colder frequently exchanges its ligneous stem for a herbaceous one, as if in anticipation of the killing frosts of winter; and, dying to the ground at the close of autumn, shoots up again in spring. The dog, transported from a temperate into a frigid region, exchanges his covering of hair for a covering of wool; when brought back again to his former habitat the wool is displaced by the original hair. And hence, and from similar instances, the derivation of an argument, good so far as it goes, for changes in adaptation to altered circumstances of the organization of plants and animals, and for the improvability of instinct.—MILLER *The Old Red Sandstone*, ch. 3, p. 36. (G. & L., 1851.)

1494. HEREDITY, UNIVERSAL RECOGNITION OF—The transmission of characteristics of species and race is admitted by everybody who deals with the body or the soul. Nobody fears to admit within these limits the fatality of birth. It is thus that every historian refers to the national character in explaining the events in the lives of a people, recognizing its persistence, and pronouncing the consequences often inevitable. The French of this day recognize themselves in the portrait of the Gauls as drawn by Julius Cæsar. The modern Greeks are in many respects the same as those whom Demosthenes addressed. If you take a young savage whose parents were hunters, vain will be your efforts to cultivate him and adapt him to the habits of civilized life. The voice of his ancestor speaks to him, incessantly recalling him to the instinct and adventures of forest life.

Heredity is the result of a very general law, by virtue of which all the anatomical elements of the body possess the property of giving direct birth to similar elements, or of determining in their own vicinity a generation of elements of the same kind (Littré et Robin). The phenomena of nutrition depend upon this same law, by virtue of which the human body, incessantly renewed, remains always identical with itself from the redistribution of atomic elements.—LORIN *General View of the Laws of Heredity (Thesis for the Degree in Medicine, 1875)*.

1495. HEROISM AND ASCETICISM IN DAILY LIFE—*Preparation for Unforeseen Emergency.*—It is not simply particular lines of discharge, but also general forms of discharge, that seem to be grooved out by habit in the brain. Just as, if we let our emotions evaporate, they get into a way of evaporating, so there is reason to suppose that if we often flinch from making an effort, before we know it the effort-making capacity will be gone, and that if we suffer the wandering of our attention, presently it will wander all the time. . . . As a final practical maxim relative to these habits of the will, we may, then, offer something like this: Keep the faculty of effort alive in you by a little gratuitous exercise every day. That is, be systematically ascetic or heroic in little unnecessary points, do every day or two something for no other reason than that you would rather not do it, so that when the hour of dire need draws nigh it may find you not unnerved and untrained to stand the test. Asceticism of this sort is like the insurance which a man pays on his house and goods. The tax does him no good at the time, and possibly may never bring him a return. But if the fire does come, his having paid it will be his salvation from ruin. So with the man who has daily inured himself to habits of concentrated attention, energetic volition, and self-denial in unnecessary things. He will stand like a tower when everything rocks around him, and when his softer fellow mortals are winnowed like chaff in the blast.—JAMES *Psychology*, vol. i, ch. 4, p. 126. (H. H. & Co., 1899.)

1496. HIGHWAYS, MODERN, FOLLOW ANCIENT BEACHES—*The "Ridge Road."*—Long curving ridges of gravel having the appearance of great railroad embankments, following the general trend of the shores of Lakes Ontario and Erie, but usually at a distance of several miles from their present borders, were noticed at an early day in the settlement of New York, Ohio, and Ontario, and correctly interpreted as being the records of previous high-water stages of the lakes they encircle. These ridges became highways of travel as civilization advanced, and gave origin to the term "ridge road," still to be seen on local maps of the region referred to. These ridges and other associated records have claimed the attention of geologists and others, and have been made the subject of special inquiry. The territory traversed by them is so extensive, however, that their study is still far from complete.—RUSSELL *Lakes of North America*, ch. 6, p. 96. (G. & Co., 1895.)

1497. HISTORY AND PHILOSOPHY—*Their Provinces Distinct.*—In the first place I have discarded the title of the "doctrine of creation," because my present business is not with the question why the objects which constitute Nature came into existence, but when they came into existence and in what order. This is as strictly a historical question as the question when the Angles and the Jutes invaded England, and whether they preceded or followed the Romans. But the question about creation is a philosophical problem, and one which can-

not be solved or even approached by the historical method. What we want to learn is whether the facts, so far as they are known, afford evidence that things arose in the way described by Milton, or whether they do not; and when that question is settled it will be time enough to inquire into the causes of their origination.—HUXLEY *American Addresses,* lect. 1, p. 18. (A., 1877.)

1498. HISTORY HAS NO RECORDS OF AGE OF STONE—Altho our knowledge of ancient times has of late years greatly increased, it is still very imperfect, and we cannot afford to neglect any possible source of information. It is evident that history cannot throw much light on the early condition of man, because the discovery—or, to speak more correctly, the use—of metal has in all cases preceded that of writing. Even as regards the Age of Bronze, we derive little information from history; and altho, as we have seen, the Age of Stone is vaguely alluded to in the earliest European writers, their statements have generally been looked upon as imaginative rather than historical, and contain, indeed, little more than the bare statement that there was a time when metal was unknown.—AVEBURY *Prehistoric Times,* ch. 13, p. 404. (A., 1900.)

1499. HISTORY IN THE ROCKS—*Geological Evidences of Life in the Past.*—The geologist has been able to turn back a few leaves of the earth's past history, and tho the pages have been defaced and mutilated by Time's unsparing hand, he is yet able to read in them of many strange vicissitudes to which the continents and oceans of our globe have been exposed. . . . He can, indeed, find the scattered remains of only a few of those old-world creatures; but he recognizes in those which have been preserved the clearest evidence that thousands of others must have existed around them. He knows that of a million creatures now existing scarcely one will leave to future ages any record of its existence; he sees whole races vanishing from the earth, leaving no trace behind them; and he is thus able to form an estimate of the enormous extent by which the creatures and races of which he can learn nothing must have outnumbered those whose scattered remains attest their former existence upon the earth.—PROCTOR *Other Worlds than Ours,* vol. i, p. 22. (Burt.)

1500. HISTORY OF MAN A HISTORY OF PROGRESS—Taken as a whole, the history of man is the history of his progressive development. It is true that everywhere and at all times we may notice individual retrogressions, or observe that crooked roads towards progress have been taken which lead only towards one-sided and external perfecting, and thus deviate more and more from the higher goal of internal and enduring perfecting. However, on the whole, the movement of development of all mankind is and remains a progressive one.—HAECKEL *History of Creation,* vol. i, ch. 12, p. 320. (K. P. & Co., 1899.)

1501. HOME, DECORATION OF—*The Original Form of Carpets.*—On festival occasions the floor had to be decorated with green, through which flowers were worked. In the winter that could only be accomplished imperfectly, and they were obliged to be satisfied with a layer of hay; but in the summer there were grass and leaves and flowers in plenty, and no house was so rich or poor but that on every festival the floor was thus decorated. The Edda testifies to this ancient custom.—GOETZ *Altnordisches Kleinleben und die Renaissance* (a lecture). (Translated for *Scientific Side-Lights.)*

1502. HOME OF THE CONDOR—*A Dweller in the Upper Air—Capacity for Change of Atmospheric Pressure.*—The region which may be regarded as the common resort of the condor begins at the elevation of Mount Etna. It embraces atmospheric strata which are from 10,000 to 19,000 feet above the level of the sea. Humming-birds also, which in their summer flights advance as far as 61° north lat. on the western coast of America, and are on the other hand found in the Archipelago of the Terra del Fuego, were seen by Von Tschudi in Puna at an elevation of 14,600 feet. There is a pleasure in comparing the largest and the smallest of the feathered inhabitants of the air. The largest among the condors found in the Cordilleras, near Quito, measure nearly 15 feet across the expanded wings. This size and the visual angle at which the birds are seen vertically above one's head afford an idea of the enormous height to which the condor soars in a clear sky. A visual angle of four minutes, for instance, would give a vertical elevation of 7,330 feet. The cavern (Mackay) of Antisana, opposite the mountain of Chussulongo, and where we measured the birds soaring over the chain of the Andes, lies at an elevation of nearly 16,000 feet above the surface of the Pacific; the absolute height which the condor reached must therefore be 23,273 feet, a height at which the barometer scarcely stands at 12.7 inches, but which, however, does not exceed that of the loftiest summit of the Himalaya. It is a remarkable physiological phenomenon that the same bird, which wheels for hours together through these highly rarefied regions, should be able suddenly, as for instance on the western declivity of the volcano of Pichincha, to descend to the seashore, and thus in the course of a few hours traverse, as it were, all climates. At heights of 23,000 feet and upwards the membranous air-sacs of the condor must undergo a remarkable degree of inflation after being filled in lower regions of the atmosphere.—HUMBOLDT *Views of Nature,* p. 237. (Bell, 1896.)

1503. HOMES, MIGRATORY BIRDS RETURN TO—*Wonderful Local Memory of Swallows Proved.*—The individual swallow,

it is now ascertained, returns from the Canaries or North Africa to the very spot on which it built its little mud mansion the previous summer, and according to the observations of the celebrated Jenner marked birds were caught at their old nests every year for three successive seasons. This fact is so remarkable that, even after allowing that the swallow tribe are gifted with extraordinary powers of localization, and that their summer homes are well defined, it is something wonderful to remember that a bird after seven months' absence can still have treasured up in its memory, through the varied fortunes and vicissitudes of two long journeys, the recollection of the landmarks necessary to guide it to and from its summer home.—BROWN *Nature-Studies*, p. 15. (Hum., 1888.)

1504. HOMOGENEOUSNESS, ASSUMED, OF MICROSCOPIC CELLS—*Properties of Water Elude Microscope.*—Let me say here that many of our physiological observers appear to form a very inadequate estimate of the distance which separates the microscopic from the molecular limit, and that, as a consequence, they sometimes employ a phraseology calculated to mislead. When, for example, the contents of a cell are described as perfectly homogeneous or as absolutely structureless, because the microscope fails to discover any structure; or when two structures are pronounced to be without difference, because the microscope can discover none, then I think the microscope begins to play a mischievous part. A little consideration will make it plain that the microscope can have no voice in the question of germ structure. Distilled water is more perfectly homogeneous than any possible organic germ. What is it that causes the liquid to cease contracting at 39° F., and to expand until it freezes? We have here a structural process of which the microscope can take no note, nor is it likely to do so by any conceivable extension of its powers.—TYNDALL *Fragments of Science*, vol. ii, ch. 8, p. 125. (A., 1897.)

1505. HOPE AND FAITH OPPOSE MATERIALISM—For there are two great enemies to materialism—one rooted in the affections, the other in the intellect. One is the power of things hoped for—a power which never dies; the other is the evidence of things not seen—and this evidence abounds in all we see. In reenforcing this evidence, and in adding to it, science is doing boundless work in the present day. It is not the extent of our knowledge, but rather the limits of it, that physical research teaches us to see and feel the most. Of course, in so far as its discoveries are really true, its influence must be for good. To doubt this were to doubt that all truth is true, its influence must be for good. To *Reign of Law*, ch. 2, p. 69. (Burt.)

1506. HOPE FOR HUMANITY'S FUTURE—*Past Gives Assurance.*—Thus, then, the most sanguine hopes for the future are justified by the whole experience of the past. It is surely unreasonable to suppose that a process which has been going on for so many thousand years should have now suddenly ceased; and he must be blind indeed who imagines that our civilization is unsusceptible of improvement, or that we ourselves are in the highest state attainable by man.—AVEBURY *Prehistoric Times*, ch. 16, p. 576. (A., 1900.)

1507. HOPEFULNESS OF SCIENCE—*Perplexities Yet Remaining.*—It must be admitted that we do not at present appear to have the means for framing a complete and consistent theory of volcanic action, but we may hopefully look forward to the time when further observation and experiment shall have removed many of the existing difficulties which beset the question, and when by the light of such future researches untenable hypotheses shall be eliminated and the just ones improved and established. —JUDD *Volcanoes*, ch. 12, p. 360. (A., 1899.)

1508. HORIZON, MENTAL, EXTENDED—*Individual Experience Not the Limit—History, Etymology, Mythology, and Religion Tributary to Psychology.*—But how is it possible to extend our experience of sensations, feelings, and thoughts? Did not mankind feel and think thousands of years ago as it feels and thinks to-day? It does, indeed, seem as tho our observation of what goes on in the mind could never extend beyond the circle to which our own consciousness confines it. But appearances are deceptive. Long ago the step was taken which raised the science of psychology above the level of this its first beginning, and extended its horizon almost indefinitely. History, dealing with the experience of all times, has furnished us with a picture in the large of the character, the impulses, and the passions of mankind. More especially is it the study of language and linguistic development, of mythology, and the history of religion and custom, which has approached more and more closely, as historical knowledge has increased, to the standpoint of psychological inquiry.—WUNDT *Psychology*, lect. 1, p. 10. (Son. & Co., 1896.)

1509. HORSE A MIGHTY ENGINE—*Adaptation to Needs of Man.*—The teeth of a horse are not less peculiar than its limbs. The living engine, like all others, must be well stoked if it is to do its work; and the horse, if it is to make good its wear and tear, and to exert the enormous amount of force required for its propulsion, must be well and rapidly fed. To this end, good cutting instruments and powerful and lasting crushers are needful. Accordingly, the twelve cutting teeth of a horse are close-set and concentrated in the fore part of its mouth, like so many adzes or chisels. The grinders or molars are large, and have an

extremely complicated structure, being composed of a number of different substances of unequal hardness. The consequence of this is that they wear away at different rates; and, hence, the surface of each grinder is always as uneven as that of a good millstone.—HUXLEY *American Addresses*, lect. 3, p. 76. (A., 1898.)

1510. HORSES, EXTINCT, IN AMERICA BEFORE COLUMBUS—It is a singular fact that, altho no horse inhabited America when discovered by Europeans, yet abundance of remains of extinct horses have been found both in North and South America in post-Tertiary and Upper Pliocene deposits; and from these an almost continuous series of modified forms can be traced in the Tertiary formation, till we reach, at the very base of the series, a primitive form so unlike our perfected animal that, had we not the intermediate links, few persons would believe that the one was the ancestor of the other.—WALLACE *Darwinism*, ch. 13, p. 260. (Hum., 1889.)

1511. HOST OF MINUTE PARTICLES, INNUMERABLE—*Unbroken Blue of Sky.*—Small in mass, the vastness in point of number of the particles of our sky may be inferred from the continuity of its light. It is not in broken patches, nor at scattered points, that the heavenly azure is revealed. To the observer on the summit of Mont Blanc, the blue is as uniform and coherent as if it formed the surface of the most close-grained solid. A marble dome would not exhibit a stricter continuity. . . . By day, this light quenches the stars; even by moonlight it is able to exclude from vision all stars between the fifth and the eleventh magnitude. It may be likened to a noise, and the feebler stellar radiance to a whisper drowned by the noise.—TYNDALL *Fragments of Science*, vol. ii, ch. 8, p. 122. (A., 1897.)

1512. HUES OF ANIMALS IN OCEAN DEPTHS OFTEN RICH AND BRILLIANT—Agassiz, in his narrative of the voyage of the "Blake," records that "some of the deep-sea corals are scarlet, deep flesh-colored, pinkish orange, and of other colors," and in referring to the Gorgonian *Iridogorgia* he says: "The species are remarkable for their elegance of form and for the brilliant luster and iridescent colors of the axis, in some of a bright emerald green, in others like burnished gold or mother-of-pearl."—HICKSON *Fauna of the Deep Sea*, ch. 4, p. 66. (A., 1894.)

1513. HUMANITY, ASCENDING SCALE OF—*The Highest Man Serves Distant Ends.*—Within the psychic life due to the cerebrum itself the same general distinction obtains, between considerations of the more immediate and considerations of the more remote. In all ages the man whose determinations are swayed by reference to the most distant ends has been held to possess the highest intelligence. The tramp who lives from hour to hour; the bohemian whose engagements are from day to day; the bachelor who builds but for a single life; the father who acts for another generation; the patriot who thinks of a whole community and many generations; and finally, the philosopher and saint whose cares are for humanity and for eternity—these range themselves in an unbroken hierarchy, wherein each successive grade results from an increased manifestation of the special form of action by which the cerebral centers are distinguished from all below them.—JAMES *Psychology*, vol. i, ch. 2, p. 23. (H. H. & Co., 1899.)

1514. HUMANITY DETHRONED—*Atheism and Materialism Result.*—Once dethrone humanity, regard it as a mere local incident in an endless and aimless series of cosmical changes, and you arrive at a doctrine which, under whatever specious name it may be veiled, is at bottom neither more nor less than atheism. On its metaphysical side atheism is the denial of anything psychical in the universe outside of human consciousness; and it is almost inseparably associated with the materialistic interpretation of human consciousness as the ephemeral result of a fleeting collocation of particles of matter. Viewed upon this side, it is easy to show that atheism is very bad metaphysics, while the materialism which goes with it is utterly condemned by modern science.—FISKE *Destiny of Man*, ch. 1, p. 12. (H. M. & Co., 1900.)

1515. HUMANITY IN ACCORD WITH HIGHER LAW—*Wholesome Restrictions on Labor.*—But as it needed the practical results of restriction—distress, discontent, and the danger of civil commotion—to bring home to the national understanding the economic error of the old commercial systems [the Corn Laws, etc.]; so also as regards the grievous results of unrestricted competition in human labor, our only effective teaching has been that of hard experience. The doctrines of Adam Smith, when applied here, were a hindrance and not a help. The political economists were, almost to a man, hostile to restrictive legislation. They did not see what would be the working of natural law upon the human will, when that will was exposed to overpowering motives under debased conditions of understanding and of heart. They did not see the higher law which Parliament was asserting when it was driven, by sheer instinctive horror of actual results, to prohibit "free" laborers from disposing as they pleased of the labor of their children.—ARGYLL *Reign of Law*, ch. 7, p. 216. (Burt.)

1516. HUMANITY RESULTS IN UTILITY—*Anesthetics Deaden Pain for Patient—Give Surgeon Calmness and Confidence.*—Anesthetics were first used in dentistry in 1846, the agent being ether, while chloroform, for more severe surgical operations,

was adopted in 1848; and tho their primary effect is only to abolish pain, they get rid of so much nervous irritation as greatly to aid in the subsequent recovery. The use of anesthetics thus renders it possible for many operations to be safely performed which, without it, would endanger life by mere shock to the system; while to the operating surgeon it gives confidence, and enables him to work more deliberately and carefully, from the knowledge that the longer time occupied will not increase the suffering of the patient or render his recovery less probable.—WALLACE *The Wonderful Century*, ch. 14, p. 147. (D. M. & Co., 1899.)

1517. HUMMING-BIRDS, HYBRIDISM NOT FOUND AMONG—*Numerous Species Keep Distinct.* — We have the emphatic declaration of Mr. Gould that among the thousands of specimens which have passed through his hands, from all the genera of this great family, he has never seen one case of mixture or hybridism between any two species, however nearly allied. But this passage is so important that I quote it entire: "It might be thought by some persons that four hundred species of birds so diminutive in size, and of one family, could scarcely be distinguished from each other; but any one who studies the subject will soon perceive that such is not the case. Even the females, which assimilate more closely to each other than the males, can be separated with perfect certainty; nay, even a tail-feather will be sufficient for a person well versed in the subject to say to what genus and species the bird from which it has been taken belongs. I mention this fact to show that what we designate a species has really distinctive and constant characters; and in the whole of my experience, with many thousands of humming-birds passing through my hands, I have never observed an instance of any variation which would lead me to suppose that it was the result of a union of two species. I write this without bias one way or the other as to the question of the origin of species. I am desirous of representing Nature in her wonderful ways as she presents herself to my attention at the close of my work, after a period of twelve years of incessant labor, and not less than twenty years of interesting study."—ARGYLL *Reign of Law*, ch. 5, p. 141. (Burt.)

1518. HUMMING-BIRDS IN SNOW-STORM—*Insect Food of Flower-loving Birds.* —Two species of humming-birds are common. *Trochilus forficatus* is found over a space of 2,500 miles on the west coast, from the hot, dry country of Lima to the forests of Terra del Fuego—where it may be seen flitting about in snow-storms. In the wooded island of Chiloe, which has an extremely humid climate, this little bird, skipping from side to side amidst the dripping foliage, is perhaps more abundant than almost any other kind. I opened the stomachs of several specimens, shot in different parts of the continent, and in all remains of insects were as numerous as in the stomach of a creeper. When this species migrates in the summer southward, it is replaced by the arrival of another species coming from the north. This second kind *(Trochilus gigas)* is a very large bird for the delicate family to which it belongs; when on the wing its appearance is singular. Like others of the genus, it moves from place to place with a rapidity which may be compared to that of *Syrphus* amongst flies, and *Sphinx* among moths; but whilst hovering over a flower, it flaps its wings with a very slow and powerful movement, totally different from that vibratory one common to most of the species, which produces the humming noise. I never saw any other bird where the force of its wings appeared (as in a butterfly) so powerful in proportion to the weight of its body. When hovering by a flower its tail is constantly expanded and shut like a fan, the body being kept in a nearly vertical position. This action appears to steady and support the bird, between the slow movements of its wings. Altho flying from flower to flower in search of food, its stomach generally contained abundant remains of insects, which I suspect are much more the object of its search than honey. The note of this species, like that of nearly the whole family, is extremely shrill.—DARWIN *Naturalist's Voyage around the World*, ch. 12, p. 271. (A., 1893.)

1519. HUNTING, A NATURAL IMPULSE — *Inherited Tendencies to Cruelty—Resolute Endeavor Needed to Overcome.*— The hunting instinct has a remote origin in the evolution of the race. The hunting and the fighting instinct combine in many manifestations. They both support the emotion of anger; they combine in the fascination which stories of atrocity have for most minds; and the utterly blind excitement of giving the rein to our fury when our blood is up (an excitement whose intensity is greater than that of any other human passion save one) is only explicable as an impulse aboriginal in character, and having more to do with immediate and overwhelming tendencies to muscular discharge than to any possible reminiscences of effects of experience or association of ideas. I say this here because the pleasure of disinterested cruelty has been thought a paradox, and writers have sought to show that it is no primitive attribute of our nature, but rather a resultant of the subtile combination of other less malignant elements of mind. This is a hopeless task. If evolution and the survival of the fittest be true at all, the destruction of prey and of human rivals must have been among the most important of man's primitive functions, the fighting and the chasing instincts must have become ingrained. . . . It is just because human bloodthirstiness is such a primitive

part of us that it is so hard to eradicate, especially where a fight or a hunt is promised as part of the fun.—JAMES *Psychology*, vol. ii, ch. 24, p. 411. (H. H. & Co., 1899.)

1520. HYPNOTISM, EFFECTS OF—*Power of Resistance Diminished—Mind Follows Accustomed Track—Judgment Beclouded.*—It [hypnotism] must be looked upon, not as a remedy of universal serviceability, but as a poison whose effect may be beneficial under certain circumstances. We find, of course, not only the dabbler in hypnotism—who has no claim to a judgment on the question, and in whose hands the practise of suggestion becomes a public nuisance—but also the physician—to whom thinking men will no more deny the right to employ this dangerous remedy in certain circumstances than that of using any other—asserting that the hypnotic sleep is not injurious, because it is not in itself a pathological condition. But surely the facts of post-hypnotic hallucination and the diminution of the power of resistance to suggestive influences furnish a refutation of this statement which no counter-arguments can shake. It is a phenomenon of common observation that frequently hypnotized individuals can when fully awake be persuaded of the wildest fables, and thenceforth regard them as passages from their own experience.—WUNDT *Human and Animal Psychology*, lect. 22, p. 335. (Son. & Co., 1896.)

1521. HYPNOTISM MAY INJURE BODY AND MIND—The chief danger of all this [unregulated use of hypnotism], it seems to me, does not lie in the abuse of post-hypnotic suggestion for criminal purposes, which may happen once in a while. Crimes have hardly as yet been committed by "mediums" as a result of suggestion. No! the great danger is that persons of insufficient medical training, working not for therapeutic ends, but "in the interests of science"—tho there is absolutely no guaranty of the real existence of their scientific devotion—may exert an influence upon the mental and bodily life of their fellow men such as, if continued for any length of time together, cannot fail to be injurious.—WUNDT *Psychology*, lect. 22, p. 336. (Son. & Co., 1896.)

1522. HYPOTHESIS OF A DESIGNING MIND—The idea or hypothesis of a designing mind, as the author of Nature—however we came by it—having possession of the field, and being one which man, himself a designer, seemingly must needs form, cannot be rivaled except by some other equally adequate for explanation, or displaced except by showing the illegitimacy of the inference. —GRAY *Darwiniana*, art. 13, p. 360. (A., 1889.)

1523. HYPOTHESIS OF A SOUL IS SATISFYING—I confess, therefore, that to posit a soul influenced in some mysterious way by the brain-states, and responding to them by conscious affections of its own, seems to me the line of least logical resistance, so far as we yet have attained.—JAMES *Psychology*, vol. i, ch. 6, p. 181. (H. H. & Co., 1899.)

1524. HYPOTHESIS OF PRIMARY ELEMENTS—*Originated Probably in India—Natural Tendency of Human Mind To Seek Underlying Principles of the Universe.*—After men had for a long time, in accordance with the earliest ideas of the Hellenic people, venerated the agency of spirits, embodied in human forms, in the creative, changing, and destructive processes of Nature, the germ of a scientific contemplation developed itself in the physiological fancies of the Ionic school. The first principle of the origin of things, the first principle of all phenomena, was referred to two causes—either to concrete material principles, the so-called elements of Nature, or to processes of rarefaction and condensation, sometimes in accordance with mechanical, sometimes with dynamic views. The hypothesis of four or five materially differing elements, which was probably of Indian origin, has continued, from the era of the didactic poem of Empedocles down to the most recent times, to imbue all opinions on natural philosophy—a primeval evidence and monument of the tendency of the human mind to seek a generalization and simplification of ideas, not only with reference to the forces, but also to the qualitative nature of matter. —HUMBOLDT *Cosmos*, vol. iii, p. 11. (H., 1897.)

1525. HYPOTHESIS, THE NEBULAR—*Formation of the Earth—A Gaseous Ring Detached from the Sun.*—Thus the earth was formed by the slow condensation of a gaseous ring detached from the sun, which, continuing afterwards to contract and to condense, gave birth later on to Venus and to Mercury. The terrestrial nebula had from that time an independent existence. It proceeded slowly to form an immense gaseous globe turning upon itself; thus condensed, heated by the molecular and constant clashing together of all the materials which compose it, the new-born earth shone with a feeble glimmer in the gloomy night of space.

From a gaseous condition it became liquid, then solid, and doubtless it continues to cool and contract even now. But its mass increases from age to age by the meteoric stones and shooting stars which continually fall upon it (more than a hundred thousand millions per annum). Will the sun give birth to a new earth? This is not probable. For this purpose it would be necessary that its rotation should be enormously accelerated; it should be 219 times more rapid.—FLAMMARION *Popular Astronomy*, pp. 73-74. (A.)

1526. ——— ——— *Objections Stated —The Best Theory That Which Best Accounts for All the Facts.*—But this ingeni-

ous theory [the nebular hypothesis] does not account for some peculiarities which are scarcely less remarkable than those on which it has been based. In particular it does not account for the strange disposition of the masses of the solar system. Why should the inner family consist of minor bodies, in the main unattended, while the outer consists of giant orbs with extensive families of satellites? Why should the innermost members of the outer family of planets be the largest, while just within there lies the family of asteroids, not only individually minute, but collectively less (as Le Verrier has proved) than Mars or even Mercury? Why should the two middle planets of the inner family be the largest members of that family? Laplace's theory gives no account of these peculiarities, nor perhaps could it be insisted that these peculiarities should be explained; yet, if any other theory should give an account of these features, explaining also the features which we have seen accounted for, then such theory would have a decided advantage over Laplace's. It is to be noticed also that Laplace's great nebulous contracting mass is a very unsatisfactory conception to begin with. No such mass could rotate as a whole. And lastly, Laplace's theory does not in any way correspond with processes still taking place within the solar system. It gives no account of the immense number of meteor-flights and comets still existing within the solar domain.—PROCTOR *Expanse of Heaven*, p. 182. (L. G. & Co., 1897.)

1527. ——— ——— *Opposed by Analysis of Existing Nebulæ.*—We have vast gaseous masses intermingled with and surrounding groups of stars, and apparently spread with exceptional richness where these stars or suns are most densely aggregated. But this is not what we should expect to find if stars were formed out of this gaseous matter. On the contrary, we should expect that where stars were most numerous there the nebulous matter would have been most completely used up, so to speak—exhausted, as it were, in the work of star-making. Nor, again, can we recognize in the substances which appear to constitute the gaseous nebulæ the fitting materials for making stars. So far as the spectroscopic analysis of the gaseous nebulæ extends, their chief constituent would appear to be the gas nitrogen, the element next in importance in their constitution being the gas hydrogen, while a third element, as yet not identified, seems to be present in their substance. I would not insist too much on this evidence; but it must not be forgotten that it is all the evidence we have; and it must be regarded as at least an unsatisfactory basis on which to rear the hypothetical development of suns like our own, in whose orb exist the glowing vapors of iron, copper, and zinc, sodium, antimony, and mercury, barium, carbon, silicon, and sulfur, and probably every single element known to our chemists.—PROCTOR *Our Place among Infinities*, p. 229. (L. G. & Co., 1897.)

1528. HYPOTHESIS VERIFIED BY EXPERIMENT—*The Undulatory Theory of Light—Conflicting Waves of Light Produce Darkness.*—Every new hypothesis of scientific value must not only furnish an exact explanation of known facts, but must also enable us to predict in kind and quantity—the phenomena which will be exhibited under any given combination of circumstances. Thus, in the case of the undulatory hypothesis of light, it was inferred as a logical consequence that if the supposition were true that light consisted of waves of an ethereal medium, then two rays of light, like two waves of water under certain conditions, should annihilate each other, and darkness be produced. The experiment was tried, and the anticipated result was obtained. It is this exact agreement of the deduction with the actual result of experience that constitutes the verification of a hypothesis, and which alone entitles it to the name of a theory, and to a place in the transactions of a scientific institution. It must be recollected that it is much easier to speculate than to investigate, and that very few of all the hypotheses imagined are capable of standing the test of scientific verification.—HENRY *Organization of Smithsonian Institution, Scientific Writings*, vol. i, p. 276. (Sm. Inst., 1886.)

1529. ICE A MILE AND A HALF IN DEPTH—*Interior of Greenland an Unknown Land.*—The interior of Greenland is reported by the few bold explorers who have crossed it to be completely buried beneath a featureless plain of snow. This covering has reached such a depth in all of the central part that not a single mountain peak is known to break the even monotony of its surface. The snow is highest and probably deepest in the central area, and descends toward the coast, thus giving the island a convex surface. The general elevation of the central portion is from 7,000 to 8,000 feet, decreasing gradually toward the coast, especially to the east and west, where the glaciers, protruding like great tongues of ice from the central region, come down to the sea. The only mountain peaks that rise above the surface of the general covering of snow are within from 50 to 75 miles of the coast. These partially buried peaks rise like islands in the sea of white. They are known to the inhabitants of the coast as *nunataks*, a convenient name that has found a place in geological literature.

The depth of the nearly universal covering of snow and ice under which Greenland is buried cannot be told, as it is impossible to determine the topography of the land beneath. The best estimates that can be made place its depth at several thousand feet. In the central portion, where the covering is apparently thickest, its

depth may be fully equal to the height of the surface above the sea, or about 8,000 feet.—RUSSELL *Glaciers of North America*, ch. 7, p. 133. (G. & Co., 1897.)

1530. ICE, CONTINUED ACTIVITY OF—At the first freezing, water, like any other substance, shrinks, but with increasing cold it expands, and in fact to such an extent that it breaks every limiting barrier, a proceeding during which it actually becomes lighter, consequently it must be constantly changing its inner structure, must be constantly developing. It is by means of this activity of ice that it gradually works to the surface the immense granite blocks which sink deep under the ice high up on the glacier. Glacial ice never contains enclosed fragments of rock.—BUCHHEISTER *Eine wissenschaftliche Alpenreise im Winter, 1832*, p. 16. (Translated for *Scientific Side-Lights.)*

1531. ICE EXPANDS BY MEANS OF AIR-BUBBLES—Glacier-ice is everywhere found honeycombed by a system of air-bubbles. Every icy surface that forms over quiet water contains a countless number of air-holes in very regular layers, of which the upper are all thin and pointed, like a bodkin, all of whose outermost sharp points turn toward the atmosphere. All of the fundamental strata of river-ice contain a complication of bubbles and nets of bubbles, that remind one of cell-tissues. The active development of these bubbles increases with the degree of cold and the formation of ice, and is the obvious reason why ice expands.—BUCHHEISTER *Eine wissenschaftliche Alpenreise im Winter, 1832*. (Translated for *Scientific Side-Lights.)*

1532. ICE, FAIRY-LAND OF—*Beauty of Alaskan Glaciers—Rich and Varied Colors—The Blue of the Crystal Mass.*—The color of the fractured and cleft ice-cliffs [of Taku glaciers] is as varied and beautiful as their ever-changing forms. The surfaces that have been longest exposed to the atmosphere are white and glittering, on account of the multitude of vesicles formed in the partially melted ice; but the clefts and caverns reveal the intense blue of the crystal mass within. In the deeper recesses the light issuing from the interior is of the darkest ultramarine, so deep that it appears almost black in contrast with the brilliant outer surface. In the full glory of an unclouded summer day the scene becomes resplendent with the reflected glories of the sea and sky. The ice-cliffs blaze and flash in the sunlight until one can scarcely believe that it is ah every-day, earthly scene that meets his admiring gaze. The observer to whom such wonders are novel may well fancy that the picture before him is but the fantasy of a dream. One is awakened from such reverie, however, by a crash like the roar of artillery, when an avalanche falls from the cliffs of light and is engulfed in the turbid waters below. The white foam shot upwards by the avalanche rises high on the icy precipice, and perhaps dislodges other tottering pinnacles, which reawaken the echoes in the neighboring mountains. After each crash, crested waves, starting away from the scene of commotion, set numerous bergs rocking, and break in lines of foam on the adjacent shore.—RUSSELL *Glaciers of North America*, ch. 6, p. 79. (G. & Co., 1897.)

1533. ICE REMOLDED BY BREAKING AND FREEZING—*Fracture and Regelation.*—[Investigation] suggested the thought that if a piece of ice—a straight prism, for example—were placed in a bent mold and subjected to pressure it would break, but that the force would also bring its ruptured surfaces into contact, and thus the continuity of the mass might be reestablished. Experiment . . . completely confirmed this surmise; the ice passed from a continuous straight bar to a continuous bent one, the transition being effected, not by a viscous movement of the particles, but through fracture and regelation.

Let the transition from curve to curve be only gradual enough, and we have the exact case of a transverse slice of a glacier. —TYNDALL *Hours of Exercise in the Alps*, ch. 1, p. 354. (A., 1898.)

1534. ICE SUPPOSED TO BE FORMED BY HEAT—*Physical Conceptions of the Ancients—Supposed Law of Contraries.*—The ideas that fire has the power of making rigid, . . . and that the formation of ice itself may be promoted by heat, are deeply rooted in the physics of the ancients and based on a fanciful theory of contraries *(Antiperistasis)*—on obscure conceptions of polarity (of exciting opposite qualities or conditions). . . . The quantity of hail produced was considered to be proportional to the degree of heat of the atmospheric strata. In the winter fishery on the shores of the Euxine, warm water was used to increase the ice formed in the neighborhood of an upright tube.—HUMBOLDT *Cosmos*, vol. iii, p. 125. (H., 1897.)

1535. ICE, TRANSPORTING POWER OF—*Rocks Borne Along Like Chips.*—In Canada, where the winter's cold is intense, in a latitude corresponding to that of central France, several tributaries of the St. Lawrence begin to thaw in their upper course, while they remain frozen over lower down, and thus large slabs of ice are set free and thrown upon the unbroken sheet of ice below. Then begins what is called the packing of the drifted fragments; that is to say, one slab is made to slide over another, until a vast pile is built up, and the whole, being frozen together, is urged onwards by the force of the dammed-up waters and drift-ice. Thus propelled, it not only forces along boulders, but breaks off from cliffs, which border the rivers, huge pieces of projecting rock. By this means several buttresses of solid masonry, which up to the year 1836

supported a wooden bridge on the St. Maurice, which falls into the St. Lawrence near the town of Trois Rivières, lat. 46° 20′, were thrown down and conveyed by the ice into the main river; and instances have occurred at Montreal of wharfs and stone buildings, from 30 to 50 feet square, having been removed in a similar manner. We learn from Captain Bayfield that anchors laid down within high-water mark, to secure vessels hauled on shore for the winter, must be cut out of the ice on the approach of spring, or they would be carried away. In 1834 the "Gulnare's" bower-anchor, weighing half a ton, was transported some yards by the ice, and so firmly was it fixed that the force of the moving ice broke a chain cable suited for a 10-gun brig, and which had rode the "Gulnare" during the heaviest gales in the gulf. Had not this anchor been cut out of the ice it would have been carried into deep water and lost.—LYELL *Principles of Geology*, bk. ii, ch. 15, p. 220. (A., 1854.)

1536. ICE, TROPICAL ANIMALS EMBALMED IN—*Glacial Epoch Came as a Surprise.*—The long summer was over. For ages a tropical climate had prevailed over a great part of the earth, and animals whose home is now beneath the equator roamed over the world from the far south to the very borders of the arctics. The gigantic quadrupeds, the mastodons, elephants, tigers, lions, hyenas, bears, whose remains are found in Europe from its southern promontories to the northernmost limits of Siberia and Scandinavia, and in America from the Southern States to Greenland and the Melville Islands, may indeed be said to have possessed the earth in those days. But their reign was over. A sudden intense winter, that was also to last for ages, fell upon our globe; it spread over the very countries where these tropical animals had their homes, and so suddenly did it come upon them that they were embalmed beneath masses of snow and ice, without time even for the decay which follows death.—AGASSIZ *Geological Sketches*, ser. i, ch. 8, p. 208. (H. M. & Co., 1896.)

1537. ICEBERGS, COLORS OF—*Blue, Gray, and White—Color Changed by Sudden Revolution—Buoyancy Causes Overthrow.*—In sailing up Muir Inlet or any other arm of the sea on the wild Alaskan shore where tide-water glaciers discharge, one notices that the bergs vary in character, but may be grouped in three quite well-defined classes. Some are of dazzling whiteness; others are of the color of turquoise or beryl; others again are dark with dirt and stones. On watching the ice-cliffs where these children of the glaciers are born, we find that when pinnacles already whitened by exposure to the air fall into the sea, they float away as white bergs. If we watch them drifting over the still water and appearing in the distance like a fleet of gleaming sails, we note that occasionally a white berg suddenly turns over with great commotion and joins the fleet having blue for their banner. The reason for the change in color is that, previous to turning over, the porous exterior of the submerged portion of the berg was dissolved away so as to expose the compact ice of the interior. The sudden reversion of position is due to unequal melting, which changes the center of gravity of the mass. A cone of ice in which the height is about equal to the diameter of the base will float with its apex down. When a berg approaches a conical form the position of greatest stability is one in which the side having the larger mass is uppermost. Bergs do not become *top-heavy* and turn over, as is sometimes stated, but become *bottom-buoyant* and tend to adjust themselves to the medium in which they float.—RUSSELL *Glaciers of North America*, ch. 6, p. 83. (G. & Co., 1897.)

1538. ——— ——— *The Blue Bergs from under Sea—Commotion Attends Emancipation.*—Blue bergs are also formed by the breaking away of portions of the submerged ice-foot of tide-water glaciers. These are frequently of large size, and rise from below the surface of the water well in advance of the visible end of the glacier. Their emergence is sudden. They bound to the surface, and rising well above it carry tons of water with them. After rocking to and fro for several minutes, as if to be sure of their freedom after centuries of imprisonment, they quiet down and float slowly away as shimmering islands of the most exquisite blue.—RUSSELL *Glaciers of North America*, ch. 6, p. 84. (G. & Co., 1897.)

1539. ICE-CLOUDS OF UPPER AIR—There is another form of cloud that is seen at this season of the year [summer] called cirrus (a curl). It takes the form of a curl at its ends. This cloud usually has a threaded shape and sometimes takes the form of a feather, and frequently forms are seen that remind you of frost-pictures on a window-pane. These clouds float very high in the atmosphere, away above the tops of the highest mountains, from six to eight miles above the level of the sea. They are formed only at a season of the year when the atmospheric conditions are most uniform. At certain times of the day and night the moisture will rise to this height before it condenses, and when it does condense it immediately freezes, which makes it take on these peculiar forms that would no doubt conform very closely to the frost-pictures on the window-pane if it were not for the disturbing influences of air currents at this altitude. The fact that they are ice- or frost-clouds instead of water-clouds gives them that peculiar whiteness and brightness of appearance. If ordinary clouds are water-dust, these high clouds may be called ice-dust. Sometimes we see them lying in bands or threads running across the sky in the direction that the wind blows. Their

form is undoubtedly a resultant of the struggle between the air currents and the tendency of crystallized water to arrange itself in certain definite lines or forms.—ELISHA GRAY *Nature's Miracles*, vol. i, ch. 9, p. 73. (F. H. & H., 1900.)

1540. ICE-CRYSTALS SHOWN IN SOLID BLOCK—*Revealing Power of Light—Hidden Structure Made Manifest.*—There is a way of showing the regularity in the structure of ice, a very simple and ingenious method devised by Professor Tyndall. His plan is this: he takes a slab of ice and causes a ray of light to pass through it at right angles to the surface of freezing, and then fall on a white screen behind Now this ray of light is accompanied by heat, and the heat serves partially to melt the ice through which it passes; but it does not melt a hole right through the ice; it melts a particle here and a particle there, and in doing so reveals the structure that was previously undiscernable. By melting a particle here and there the transparency of the ice is interrupted, and the screen now reveals a number of figures known as ice-flowers, each of which has a bright spot in the center, and, like a snow-crystal, has six rays, inclined to one another at precisely the same angle, and variously adorned with symmetrical outgrowths. — CHISHOLM *Nature-Studies*, p. 27. (Hum., 1888.)

1541. ICE-HOUSE, A NATURAL—*Frozen Drifts Buried for Ages—Siberian Mammoths.*—If it be true that the carcass of the mammoth was embedded in pure ice, there are two ways in which it may have been frozen in. We may suppose the animal to have been overwhelmed by drift-snow. I have been informed by Dr. Richardson that in the northern parts of America, comprising regions now inhabited by many herbivorous quadrupeds, the drift-snow is often converted into permanent glaciers. It is commonly blown over the edges of steep cliffs, so as to form an inclined talus hundreds of feet high; and when a thaw commences, torrents rush from the land and throw down from the top of the cliff alluvial soil and gravel. This new soil soon becomes covered with vegetation, and protects the foundation of snow from the rays of the sun. Water occasionally penetrates into the crevices and pores of the snow; but, as it soon freezes again, it serves the more rapidly to consolidate the mass into a compact iceberg. It may sometimes happen that cattle grazing in a valley at the base of such cliffs, on the borders of a sea or, river, may be overwhelmed and at length enclosed in solid ice, and then transported towards the polar regions.—LYELL *Principles of Geology*, bk. i, ch. 6, p. 85. (A., 1854.)

1542. ICE-SHEET OVER NORTHERN ITALY—*The Glacial Epoch.*—The glaciers on the southern sides of the Alps were hardly less extensive than on the northern. They descended the valleys, they passed over the sites of the Italian lakes and on to the plains of Piedmont and Lombardy. 'Round one group of moraines the tide of battle ebbed and flowed in the struggle of Solferino.—BONNEY *Ice-work, Present and Past*, pt. i, ch. 1, p. 35. (A., 1896.)

1543. ICE-STORMS IN FORESTS—*Melting Snow Congealed on Trees—Blocks of Ice Hurled Down.*—Snow may act destructively . . . by giving rise to what are known as ice-storms in forests. When snow falls in forests, and especially in forests of coniferous trees, such as are most abundant in those regions where snow falls most plentifully, the branches of these evergreens become laden with a heavy weight of snow, which they may bear until the snow has been converted by partial melting and subsequent refreezing into solid lumps of ice. These present a still greater surface for the reception of fresh snow, which may be converted into ice in its turn. Sometimes these accumulations attain such a weight that the branches can no longer support them. The topmost, weakest branches give way and fall down with the lumps of ice that they carry. These, acquiring impetus as they fall, strike against the lower branches and break them off. Thus the process of destruction is accelerated. The agitation is communicated to the contiguous trees, and from these to others, and thus in a brief space of time large areas in a forest may be in great part destroyed.—CHISHOLM *Nature-Studies*, p. 32. (Hum., 1888.)

1544. IDEA BEHIND PHENOMENA—*The First Law of Motion—Not One Instance of Its Operation Ever Known—Revealed to Scientific Faith Only.*—The law is that all motion is in itself (that is to say, except as affected by extraneous forces) uniform in velocity and rectilinear in direction. Thus according to this law a body moving, and not subject to any extraneous force, would go on moving forever at the same rate of velocity, and in an exactly straight line.

Now, there is no such motion as this existing on the earth or in the heavens. It is an abstract idea of motion which no man has ever or can ever see exemplified. Yet a clear apprehension of this abstract idea was necessary to a right understanding and to the true explanation of all the motions which are actually seen. It was long before this idea was arrived at. There was a real difficulty in conceiving it, because not only is there no such motion in Nature, but there is no possibility by artificial means of producing it. It is impossible to release any moving body from the impulses of extraneous force. The first law of motion is therefore a purely abstract idea. It represents a rule which never operates as we conceive it in itself, but is always complicated with other rules which produce a corre-

sponding complication in result. Like many other laws of the same class, it was discovered, not by looking outward, but by looking inward; not by observing, but by thinking. —ARGYLL *Reign of Law*, ch. 2, p. 65. (Burt.)

1545. IDEA OF MATHEMATICIAN REALIZED IN CRYSTAL—*Theory of Undulations Verified.*—Effects [of refraction] which, without a theoretic clue, would leave the human mind in a jungle of phenomena without harmony or relation, were organically connected by the theory of undulation.

The theory was applied and verified in all directions, Airy being especially conspicuous for the severity and conclusiveness of his proofs. The most remarkable verification fell to the lot of the late Sir William Hamilton, of Dublin, who, taking up the theory where Fresnel had left it, arrived at the conclusion that at four special points of the "wave-surface" in double-refracting crystals the ray was divided, not into two parts, but into an infinite number of parts, forming at these points a continuous conical envelope instead of two images. No human eye had ever seen this envelope when Sir William Hamilton inferred its existence. He asked Dr. Lloyd to test experimentally the truth of his theoretic conclusion. Lloyd, taking a crystal of aragonite, and following with the most scrupulous exactness the indications of theory, cutting the crystal where theory said it ought to be cut, observing it where theory said it ought to be observed, discovered the luminous envelope which had previously been a mere idea in the mind of the mathematician.—TYNDALL *Lectures on Light*, p. 212. (A., 1898.)

1546. IDEAS, ABSTRACT, OF SLOW GROWTH—*Not To Be Attributed to Primitive Man—Conception of Energy or Force Late and Difficult—Powers of Nature Regarded as Energies of Persons.*—When, again, we are told by Sanskrit scholars that the earliest religious conceptions of the Aryan race, as exhibited in the Veda, were pantheistic, and that the gods they worshiped were "deifications" of the forces or powers of Nature, we are to remember that this is an interpretation, and not a fact. It is an interpretation, too, which assumes the familiarity of the human mind, in the ages of its infancy, with one of the most doubtful and difficult conceptions of modern science—namely, the abstract conception of energy or force as an inseparable attribute of matter. The only fact, divested of all preconceptions, which these scholars have really ascertained is that in compositions which are confessedly poetical the energies of Nature were habitually addressed as the energies of personal or living beings. But this fact does not in the least involve the supposition that the energies of Nature which are thus addressed had, at some still earlier epoch, been regarded under the aspect of material forces, and had afterwards come to be personified; nor does it in the least involve the other supposition that, when so personified, they were really regarded as so many different beings absolutely separate and distinct from each other. Both of these suppositions may indeed be matter of argument, but neither of them can be legitimately assumed.—ARGYLL *Unity of Nature*, ch. 12, p. 303. (Burt.)

1547. IDEAS NOT OBJECTS, BUT PROCESSES—*Comparison of Thinking to Writing.*—As a matter of fact, ideas, like all other mental experiences, are not objects, but processes, occurrences. The idea which we refer back to a previous one, when we apprehend it as similar to that, is no more the earlier idea itself than the word which we write or the picture which we draw is identical with the same word which we wrote previously or the similar drawing which we made some time ago. Indeed, you will see, if you consider the complex conditions under which our inner experience arises, that nothing like the same degree of similarity between the earlier and the later product can be expected here as may be found under certain circumstances in the field of external actions like writing and drawing. The circumstance that new processes exhibit relations and similarity to others previously existing can no more prove the continued existence of the idea as such than it can be inferred from the similarity of the movement of the pen in writing a definite word now to that involved on a former occasion, that this movement has continued to exist in an invisible form from the time it was first made, and has simply become visible again when we have written the word anew.—WUNDT *Psychology*, lect. 16, p. 236. (Son. & Co., 1896.)

1548. IDENTIFICATION OFTEN FALLACIOUS—*Witness Sees the Expected—Forms Recognized in "Materializing Séances."*—Testimony to personal identity is proverbially fallacious for similar reasons [viz.: illusion through preconception]. A man has witnessed a rapid crime or accident, and carries away his mental image. Later he is confronted by a prisoner whom he forthwith perceives in the light of that image, and recognizes, or "identifies," as a participant, altho he may never have been near the spot. Similarly at the so-called "materializing séances" which fraudulent mediums give: in a dark room a man sees a gauze-robed figure who in a whisper tells him she is the spirit of his sister, mother, wife, or child, and falls upon his neck. The darkness, the previous forms, and the expectancy have so filled his mind with premonitory images that it is no wonder he perceives what is suggested. These fraudulent "séances" would furnish most precious documents to the psychology of perception, if they could only be satisfactorily inquired into.—JAMES *Psychology*, vol. ii, ch. 19, p. 97. (H. H. & Co., 1899.)

1549. IDIOCY A MANUFACTURED ARTICLE—*Recompense of Violated Law—Intemperance a Fruitful Cause of Imbecility.*—The congenital idiot is deprived of his human birthright; for he is born with such a defect of brain that he cannot display any or can only display very feeble and imperfect mental functions. From no fault of his own is he thus afflicted, seeing that he must be held innocent of all offense but the offense of his share of original sin; but it is nowise so clear that it is not from some fault of his parents. It is all too true that in many cases there has observably been a neglect or disregard of the laws which govern the progress of human development through the ages. Idiocy is indeed a manufactured article; and altho we are not always able to tell how it is manufactured, still its important causes are known and are within control. Many cases are distinctly traceable to parental intemperance and excess. Out of 300 idiots in Massachusetts, Dr. Howe found as many as 145 to be the offspring of intemperate parents; and there are numerous scattered observations which prove that chronic alcoholism in the parent may directly occasion idiocy in the child. [See ALCOHOL and HEREDITY.] I think, too, that there is no reasonable question of the ill-effects of marriages of consanguinity; that their tendency is to produce degeneracy of the race, and idiocy as the extremest form of such degeneracy.—MAUDSLEY *Body and Mind*, lect. 2, p. 44. (A., 1898.)

1550. IGNORANCE, CONSCIOUS, A STEP TOWARD KNOWLEDGE—It [Professor Lockyer's theory of dissociation of chemical elements] brings us face to face with the mysteries of the ultimate constitution of matter, and of its relations to the vibrating medium filling space. It makes our ignorance on these subjects seem at once more dense and more definite. Nevertheless, this in itself (tho the saying appears paradoxical) constitutes an advance. Unfelt ignorance persists. Ignorance that is stricken with uneasy self-consciousness is already on the way to be turned into knowledge.—CLERKE *History of Astronomy*, pt. ii, ch. 4, p. 261. (Bl., 1893.)

1551. IGNORANCE, HUMAN, IMAGINES CAPRICE IN NATURE—The flowers of orchids, in their strange and endless diversity of shape, may be compared with the great vertebrate class of fish, or still more appropriately with tropical homopterous insects, which appear to us as if they had been modeled in the wildest caprice, but this no doubt is due to our ignorance of their requirements and conditions of life.—DARWIN *Fertilization of Orchids*, ch. 7, p. 224. (A., 1898.)

1552. IGNORANCE NOT THE MOTHER OF THE SUBLIME—*Science Exalts to a Truer Sublimity—The Facts of Astronomy Surpass All Poetic Ideals.*—Writers who know nothing of the true poetry of modern science have supposed that the perception of the sublime is born of ignorance, and that to admire it is necessary not to know. This is assuredly a strange error, and the best proof of it is found in the captivating charm and the passionate admiration which divine science now inspires, not in some rare minds only, but in thousands of intellects, in a hundred thousand readers impassioned in the search for truth, surprised, almost ashamed, at having lived in ignorance of and indifference to these splendid realities, anxious to incessantly enlarge their conception of things eternal, and feeling admiration increasing in their dazzled minds in proportion as they penetrate farther into infinitude. What was the universe of Moses of Job, of Hesiod, or of Cicero, compared to ours! Search through all the religious mysteries, in all the surprises of art, painting music, the theater, or romance; search for an intellectual contemplation which produces in the mind the impression of truth of grandeur, of the sublime, like astronomical contemplation!—FLAMMARION *Popular Astronomy*, bk. vi, ch. 1, p. 554. (A.)

1553. IGNORANCE OF MAN AS TO RELATIONS OF ORGANIC LIFE—*Alleviations of Struggle for Life.*—It is good thus to try in imagination to give any one species an advantage over another. Probably in no single instance should we know what to do. This ought to convince us of our ignorance on the mutual relations of all organic beings, a conviction as necessary as it is difficult to acquire. All that we can do is to keep steadily in mind that each organic being is striving to increase in a geometrical ratio; that each, at some period of its life, during some season of the year, during each generation, or at intervals, has to struggle for life and to suffer great destruction. When we reflect on this struggle we may console ourselves with the full belief that the war of Nature is not incessant, that no fear is felt, that death is generally prompt, and that the vigorous, the healthy, and the happy survive and multiply.—DARWIN *Origin of Species*, ch. 3, p. 72. (Burt.)

1554. IGNORANCE OF NATURAL LAWS—*Air Not To Be Navigated by Buoyancy.*—On the earth and on the sea man has attained to powers of locomotion with which in strength, endurance, and in velocity, no animal movement can compare. But the air is an element on which he cannot travel—an ocean which he cannot navigate. The birds of heaven are still his envy, and on the paths they tread he cannot follow. As yet! for it is not certain that this exclusion is to be perpetual. His failure has resulted quite as much from his ignorance of natural laws as from his inability to meet the conditions which they demand. All attempts to guide bodies buoyant in the air must be fruitless. Balloons are mere toys. No

flying animal has ever been formed on the principle of buoyancy. Birds and bats and dragons have been all immensely heavier than the air, and their weight is one of the forces most essential to their flight. Yet there is a real impediment in the way of man navigating the air—and that is the excessive weight of the only great mechanical moving powers hitherto placed at his disposal. When science shall have discovered some moving power greatly lighter than any we yet know, in all probability the problem will be solved. But of one thing we may be sure—that if man is ever destined to navigate the air it will be in machines formed in strict obedience to the mechanical laws which have been employed by the Creator for the same purpose in flying animals.—ARGYLL *Reign of Law*, ch. 3, p. 101. (Burt.)

1555. ILLUMINATION OF OCEAN BY PHOSPHORESCENT ANIMALS—To give an example of the extent to which the illumination due to phosphorescent organisms may reach, I may quote a passage from the writings of the late Sir Wyville Thomson:

"After leaving the Cape Verde Islands the sea was a perfect blaze of phosphorescence. There was no moon, and altho the night was perfectly clear and the stars shone brightly, the luster of the heavens was fairly eclipsed by that of the sea. It was easy to read the smallest print, sitting at the after-port in my cabin, and the bows shed on either side rapidly widening wedges of radiance so vivid as to throw the sails and rigging into distinct lights and shadows."—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 26. (A., 1894.)

1556. ILLUSION AT SEA—*Empty Cap and Coat Assume Guise of Engineer.*—I was lying in my berth in a steamer listening to the sailors holystone the deck outside, when, on turning my eyes to the window, I perceived with perfect distinctness that the chief engineer of the vessel had entered my stateroom, and was standing looking through the window at the men at work upon the guards. Surprised at his intrusion, and also at his intentness and immobility, I remained watching him and wondering how long he would stand thus. At last I spoke; but getting no reply sat up in my berth, and then saw that what I had taken for the engineer was my own cap and coat hanging on a peg beside the window. The illusion was complete; the engineer was a peculiar-looking man, and I saw him unmistakably; but after the illusion had vanished I found it hard voluntarily to make the cap and coat look like him at all.—JAMES *Psychology*, vol. ii, ch. 19, p. 101. (H. H. & Co., 1899.)

1557. ILLUSION DUE TO RELATIVE SENSATIONS—*Opposites, as Heat and Cold, Combine in a Contradiction.*—Another striking example is that of our sense of the temperature of objects, which is known to be strictly relative to a previous sensation, or more correctly to the momentary condition of the organ. Yet, tho every intelligent person knows this, the deeply rooted habit of making sensation the measure of objective quality asserts its sway, and frequently leads us into illusion. The well-known experiment of first plunging one hand in cold water, the other in hot, and then dipping them both in tepid, is a startling example of this organized tendency. For here we are strongly disposed to accept the palpable contradiction that the same water is at once warm and cool.—SULLY *Illusions*, ch. 4, p. 65. (A., 1897.)

1558. ILLUSION OF ABSENCE OF LIFE—*Earth at Few Miles' Distance Seems a Dead World.*—When [astronomers] declare that the moon is uninhabited because they see nothing moving, they are singularly deceived in the value of telescopic testimony. At some miles high in a balloon, with a clear sky and beautiful sunshine, we distinguish with the naked eye towns, woods, fields, meadows, rivers, roads; but we see nothing moving, and the impression felt directly (I have often experienced it in my aerial voyages) is of silence, solitude, and the absence of life. Living beings are no longer visible, and if we did not know that there are harvest-men in the fields, flocks in the meadows, birds in the woods, fish in the waters, there is nothing to make us realize their existence. If, then, the earth seems like a dead world when seen from only a few miles' distance, what is it but illusion to assert that the moon is truly a dead world, because we view it at 120 miles or more? for it is only exceptionally that we can use the highest magnifying powers, and in general we do not apply to the observation of the moon powers exceeding a thousand. What, then, can we see of life at such a distance? Assuredly nothing, for forests, plants, cities, all would disappear.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 6, p. 148. (A.)

1559. ILLUSION OF MOVEMENT—*Stationary Train Thought To Be in Motion—Sensation Due to Mental Inference.*—There is an illusion of movement of the opposite sort with which every one is familiar at railway stations. Habitually, when we ourselves move forward, our entire field of view glides backward over our retina. When our movement is due to that of the windowed carriage, car, or boat in which we sit, all stationary objects visible through the window give us a sensation of gliding in the opposite direction. Hence, whenever we get this sensation, of a window with all objects visible through it moving in one direction, we react upon it in our customary way, and perceive a stationary field of view, over which the window, and we ourselves inside of it, are passing by a motion of our own. Consequently when another train comes alongside of ours in a station, and fills the

entire window, and, after standing still awhile, begins to glide away, we judge that it is our train which is moving, and that the other train is still. If, however, we catch a glimpse of any part of the station through the windows, or between the cars of the other train, the illusion of our own movement instantly disappears, and we perceive the other train to be the one in motion. This, again, is but making the usual and probable inference from our sensation.—JAMES *Psychology*, vol. ii, ch. 19, p. 90. (H. H. & Co., 1899.)

1560. ILLUSION OF PERCEPTION—*A Mother's Needless Terror—The Seeing of Complementary Colors.*—The eye also under some circumstances may lose its sensibility for particular colors, or be thrown into such an unusual state as to present all objects to the mind under the appearance of a false color. Thus, if a person looks fixedly for a time at a bright red object and then turns his eye to a white wall, he will perceive a green image of the red object depicted on the white surface. A lady of our acquaintance was once thrown into an alarming but laughable paroxysm of terror by an effect of this kind. She had been for some hours attentively sewing on a bright crimson dress, when her attention was directed towards her child, who in its sport had thrown itself on the carpet; its face appeared of the most ghastly hue, and the affrighted mother screamed in agony that her child was in convulsions; the other inmates of the house hastened to her assistance, but they were surprised to find the little one smiling in perfect health. The sanity of the mother became the natural object of solicitude until the effect was properly referred to the impression made on her eye by the crimson cloth.—HENRY *Color-Blindness, Scientific Writings*, vol. i, p. 234. (Sm. Inst., 1886.)

1561. ILLUSION THE LOT OF ALL MEN—*Absolute Truth Sought in Vain.*—Notwithstanding the flattering supposition of common sense, that illusion is essentially an incident in abnormal life, the careful observer knows well enough that the case is far otherwise. There is, indeed, a view of our race diametrically opposed to the flattering opinion referred to above, namely, the humiliating judgment that all men habitually err, or that illusion is to be regarded as the natural condition of mortals. This idea has found expression not only in the cynical exclamation of the misanthropist that most men are fools, but also in the cry of despair that sometimes breaks from the weary searcher after absolute truth, and from the poet when impressed with the unreality of his early ideals.—SULLY *Illusions*, ch. 1, p. 2. (A., 1897.)

1562. ILLUSION THROUGH MENTAL SUGGESTION—The following, related by Dr. Tuke, shows in an admirable manner how similar impressions may be revived, and falsify the perceptions of a number of persons:

"During the conflagration at the Crystal Palace, in the winter of 1866-67, when the animals were destroyed by the fire, it was supposed that the chimpanzee had succeeded in escaping from its cage. Attracted to the roof with the expectation in full force, men saw the unhappy animal holding on to it and writhing in agony to get astride one of the iron ribs. It need not be said that its struggles were watched by those below with breathless suspense, and, as the newspapers informed us, 'with sickening dread.' But there was no animal whatever there; and all this feeling was thrown away upon a tattered piece of blind, so torn as to resemble to the eye of fancy the body, arms, and legs of an ape!"—ELDRIDGE-GREEN *Memory and Its Cultivation*, pt. i, ch. 7, p. 172. (A., 1900.)

1563. ILLUSION THROUGH PRECONCEPTION—*Seeing the Expected.*—We [sometimes] perceive a wrong object because our mind is full of the thought of it at the time, and any sensation which is in the least degree connected with it touches off, as it were, a train already laid, and gives us a sense that the object is really before us. Here is a familiar example:

"If a sportsman, while shooting woodcock in cover, sees a bird about the size and color of a woodcock get up and fly through the foliage, not having time to see more than that it is a bird of such a size and color, he immediately supplies by inference the other qualities of a woodcock, and is afterwards disgusted to find that he has shot a thrush. I have done so myself, and could hardly believe that the thrush was the bird I had fired at, so complete was my mental supplement to my visual perception."

As with game, so with enemies, ghosts, and the like. Any one waiting in a dark place and expecting or fearing strongly a certain object, will interpret any abrupt sensation to mean that object's presence. The boy playing "I spy," the criminal skulking from his pursuers, the superstitious person hurrying through the woods or past the churchyard at midnight, the man lost in the woods, the girl who tremulously has made an evening appointment with her swain, all are subject to illusions of sight and sound which make their hearts beat till they are dispelled.—JAMES *Psychology*, vol. ii, ch. 19, p. 95. (H. H. & Co., 1899.)

1564. ILLUSIONS IN NATURE—*The Specter of the Brocken.*—There is a wonderful exhibition of shadow to be seen under certain conditions of the atmosphere on one of the peaks of the Hartz Mountains, called the Brocken. If one or more people stand on the summit at sunrise they can see an enlarged shadow of themselves as well as the top of the mountain, together with a house with a tower on it, standing out against the sky in enormous proportions; the clouds and mist form a screen to catch the shadows, and, while it is as easily ex-

plained as the shadow of a tree in the summer sunshine, it has an uncanny appearance. It is called the "Specter of the Brocken," and has been looked upon with superstitious awe by the ignorant people for ages past. This specter may be seen both at sunrise and at sunset, but of course on opposite sides of the mountain.—ELISHA GRAY *Nature's Miracles*, vol. ii, ch. 27, p. 215. (F. H. & H., 1900.)

1565. ILLUSIONS OF SIGHT—*Spectrum Seen in Darkness—Newton's Experience.*—Sir Isaac Newton was able to recall [the spectrum] by going into the dark and directing his mind intensely, "as when a man looks earnestly to see a thing which is difficult to be seen," and this [image], after a frequent repetition of this process, came (he says) to return "as often as I began to meditate on the phenomena, even tho I lay in bed at midnight with my curtains drawn." For altho phenomena of this class are often regarded as ocular spectra produced by retinal change, their reproduction by mental states seems to place them in the same category as the visual sensations which are distinctly reproduced by memory—that is, by cerebral change. In fact, there is such a gradational transition from the one state to another that it seems clear that they have a common origin.—CARPENTER *Mental Physiology*, bk. i, ch. 4, p. 165. (A., 1900.)

1566. ILLUSIONS OF TOUCH—*False Interpretation of True Perception.*—The different degrees of sensitiveness possessed by different parts may give rise to errors of judgment in estimating the distance between two points where the skin is touched. Thus, if blunted points of a pair of compasses (maintained at a constant distance apart) be slowly drawn over the skin of the cheek toward the lips, it is almost impossible to resist the conclusion that the distance between the points is gradually increasing. When they reach the lips they seem to be considerably further apart than on the cheek. Thus, too, our estimate of the size of a cavity in a tooth is usually exaggerated when based upon sensation derived from the tongue alone. Another curious illusion may here be mentioned. If we close the eyes, and place a small marble or pea between the crossed fore and middle fingers, we seem to be touching two marbles. This illusion is due to an error of judgment. The marble is touched by two surfaces which, under ordinary circumstances, could only be touched by two separate marbles, hence the mind, taking no cognizance of the fact that the fingers are crossed, forms the conclusion that two sensations are due to two marbles.—BAKER *Handbook of Physiology*, vol. ii, ch. 19, p. 165. (W. W., 1885.)

1567. ILLUSIONS USED IN HEATHEN RITES—*Images of Gods Formed by Concave Mirrors.*—A stick half immersed in water always looks broken, however well we may know that the appearance is due to the bending of the rays of light. Similarly, an echo always sounds as tho it came from some object in the direction in which the air-waves finally travel to the ear, tho we are perfectly sure that these undulations have taken a circuitous course. It is hardly necessary to remind the reader that the deeply organized tendency to mistake the direction of the visible or audible object in these cases has from remote ages been made use of as a means of popular delusion. Thus, we are told by Sir D. Brewster, in his entertaining "Letters on Natural Magic" (letter iv), that the concave mirror was probably used as the instrument for bringing the gods before the people. The throwing of the images formed by such mirrors upon smoke or against fire, so as to make them more distinct, seems to have been a favorite device in the ancient art of necromancy.—SULLY *Illusions*, ch. 5, p. 73. (A., 1897.)

1568. IMAGES OF MEMORY MAY HAVE A KIND OF OBJECTIVE PRESENT EXISTENCE—It is only when the sting of the recollection is removed, when, for example, the calling-up of the image of a lost friend is no longer accompanied with the bitterness of futile longing, that a healthy mind ventures to nourish recollections of such remote events and to view these as part of its recent experiences. In this case the mnemonic image becomes transformed into a kind of present emotional possession, an element of that idealized and sublimated portion of our experience with which all imaginative persons fill up the emptiness of their actual lives, and to which the poet is wont to give an objective embodiment in his verse.—SULLY *Illusions*, ch. 10, p. 261. (A., 1897.)

1569. IMAGINATION, CREATIVE—*Mozart's Composing.*—Mozart describes thus his manner of composing: First, bits and crums of the piece come and gradually join together in his mind; then, the soul getting warmed to the work, the thing grows more and more, "and I spread it out broader and clearer, and at last it gets almost finished in my head, even when it is a long piece, so that I can see the whole of it at a single glance in my mind, as if it were a beautiful painting or a handsome human being; in which way I do not hear it in my imagination at all as a succession—the way it must come later—but all at once, as it were. It is a rare feast! All the inventing and making goes on in me as in a beautiful strong dream. But the best of all is the hearing of it all at once."—JAMES *Psychology*, vol. i, ch. 9, p. 255. (H. H. & Co., 1899.)

1570. IMAGINATION DISTORTING FACT—*Seaman's Strange Tale—Scientific Basis of Story.*—Another animal, a zoophyte, consists of a thin, straight, fleshy stem,

with alternate rows of polypi on each side, and surrounding an elastic stony axis, varying in length from eight inches to two feet. The stem at one extremity is truncate, but at the other is terminated by a vermiform fleshy appendage. . . . At low water hundreds of these zoophytes might be seen, projecting like stubble, with the truncate end upwards, a few inches above the surface of the muddy sand. When touched or pulled they suddenly drew themselves in with force, so as nearly or quite to disappear. . . . It is always interesting to discover the foundation of the strange tales of the old voyagers; and I have no doubt but that the habits of this *Virgularia* explain one such case. Captain Lancaster, in his voyage in 1601, narrates that on the sea-sands of the Island of Sombrero, in the East Indies, he "found a small twig growing up like a young tree, and on offering to pluck it up it shrinks down to the ground, and sinks, unless held very hard. On being plucked up, a great worm is found to be its root, and as the tree groweth in greatness, so doth the worm diminish; and as soon as the worm is entirely turned into a tree it rooteth in the earth, and so becomes great. This transformation is one of the strangest wonders that I saw in all my travels: for if this tree is plucked up while young, and the leaves and bark stripped off, it becomes a hard stone when dry, much like white coral: thus is this worm twice transformed into different natures. Of these we gathered and brought home many."—DARWIN *Naturalist's Voyage around the World*, ch. 5, p. 99. (A., 1898.)

1571. IMAGINATION ELIMINATED— *Photography vs. Drawing—The Artist Has More Discretion—The Camera More Absolute Faithfulness—Conflict of Testimony between Conscientious Observers.*—The skilful draftsman can show in the same picture details differing to any extent in intensity, while the photograph is, so to speak, limited to the reproduction of only one certain class of details at a time. Still we can always be sure that whatever a photograph does show is an autographic representation of fact, and not a figment of the imagination. This is not the case with drawings; for it is remarkable how widely two conscientious artists will differ in their representations of the same object, seen by both with the same telescope, and under the same circumstances. As an accurate record of the number, position, and magnitude of the solar spots at any given time, the photograph is, of course, unexceptionable.—YOUNG *The Sun*, ch. 2, p. 51. (A., 1898.)

1572. IMAGINATION ESSENTIAL TO SCIENTIFIC RESEARCH—An intellectual and ideal combination of the facts already established often guides almost imperceptibly the course of presage, elevating it as by a power of inspiration. How much has been enounced among the Indians and Greeks and during the Middle Ages, regarding the connection of natural phenomena, which, at first either vague or blended with the most unfounded hypotheses, has, at a subsequent epoch, been confirmed by sure experience and then been recognized as a scientific truth! The presentient fancy and the vivid activity of spirit which animated Plato, Columbus, and Kepler must not be disregarded, as if they had effected nothing in the domain of science, or as if they tended, of necessity, to draw the mind from the investigation of the actual.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 107. (H., 1897.)

1573. IMAGINATION IMPORTS FALSE MATERIAL INTO SCENES OF MEMORY— Not only does our idea of the past become inexact by the mere decay and disappearance of essential features: it becomes positively incorrect through the gradual incorporation of elements that do not properly belong to it. Sometimes it is easy to see how these extraneous ideas get imported into our mental representation of a past event. Suppose, for example, that a man has lost a valuable scarf-pin. His wife suggests that a particular servant, whose reputation does not stand too high, has stolen it. When he afterwards recalls the loss, the chances are that he will confuse the fact with the conjecture attached to it, and say he remembers that this particular servant did steal the pin. Thus, the past activity of imagination serves to corrupt and partially falsify recollections that have a genuine basis of fact.—SULLY *Illusions*, ch. 10, p. 264. (A., 1897.)

1574. IMAGINATION IN SCIENCE— *A Constructive Power—Ideas of Cause, Gravitation, Atomic Theory, and Kepler's Laws, Its Products.*—With accurate experiment and observation to work upon, imagination becomes the architect of physical theory. Newton's passage from a falling apple to a falling moon was an act of the prepared imagination, without which the "laws of Kepler" could never have been traced to their foundations. Out of the facts of chemistry the constructive imagination of Dalton formed the atomic theory. Davy was richly endowed with the imaginative faculty, while with Faraday its exercise was incessant, preceding, accompanying, and guiding all his experiments. His strength and fertility as a discoverer are to be referred in great part to the stimulus of his imagination. Scientific men fight shy of the word because of its ultrascientific connotations; but the fact is that without the exercise of this power our knowledge of Nature would be a mere tabulation of coexistences and sequences. We should still believe in the succession of day and night, of summer and winter; but the conception of force would vanish from our universe; causal relations would disappear, and with them that science which is now binding the

parts of Nature into an organic whole.—TYNDALL *Fragments of Science*, vol. ii, ch. 8, p. 104. (A., 1897.)

1575. ——— ——— *Checks of Reason and Observation.*—Imagination is necessary to the man of science, and we could not reason on our present subject without the power of presenting mentally a picture of the earth's crust cracked and fissured by the forces which produced its upheaval. Imagination, however, must be strictly checked by reason and by observation.—TYNDALL *Hours of Exercise in the Alps*, ch. 20, p. 230. (A., 1898.)

1576. ——— ——— *Mythology Suggests Botanical Names.*—Linnæus gave the name *Andromeda* after the Ethiopian maid whose mother's over-great boasts of the daughter's beauty made her the victim of Poseidon's wrath. Linnæus justified his procedure by a remarkable play of fancy: "This most choice and beautiful virgin gracefully erects her long and shining neck (the peduncle), her face with its rosy lips (the corolla) far excelling the best pigment. She kneels on the ground with her feet bound (the lower part of the stem incumbent), surrounded with water, and fixed to a rock (a projecting clod), exposed to frightful dragons (frogs and newts). She bends her sorrowful face (the flower) towards the earth, stretches up her innocent arms (the branches) toward heaven, worthy of a better place and happier fate, until the welcome Perseus (summer), after conquering the monster, draws her out of the water and renders her a fruitful mother, when she raises her head (the fruit) erect."—GILL *Address before the Amer. Assoc. for the Advancement of Science, Smithsonian Report for 1896*, pp. 457-83.

1577. ——— ——— *Producing Effects in the World of Fact.*—This conception of physical theory [of light] implies, as you perceive, the exercise of the imagination. Do not be afraid of this word, which seems to render so many respectable people, both in the ranks of science and out of them, uncomfortable. That men in the ranks of science should feel thus is, I think, a proof that they have suffered themselves to be misled by the popular definition of a great faculty instead of observing its operation in their own minds. Without imagination we cannot take a step beyond the bourn of the mere animal world, perhaps not even to the edge of this one. But, in speaking thus of imagination, I do not mean a riotous power which deals capriciously with facts, but a well-ordered and disciplined power, whose sole function is to form conceptions which the intellect imperatively demands. Imagination, thus exercised, never really severs itself from the world of fact. This is the storehouse from which the materials for all its pictures are derived; and the magic of its art consists, not in creating things anew, but in so changing the magnitude, position, and other relations of sensible things as to render them fit for the requirements of the intellect in the subsensible world.—TYNDALL *Lectures on Light*, lect. 2, p. 43. (A., 1898.)

1578. IMAGINATION MAY MAKE IDEAL WORLD ALMOST REAL—The higher feelings or emotions are distinguished from the simple sense-feelings in being largely representative. Thus, a feeling of contentment at any moment, tho no doubt conditioned by the bodily state and the character of the organic sensations, or cœnesthesis, commonly depends for the most part on intellectual representations of external circumstances or relations, and may be called an ideal foretaste of actual satisfactions, such as the pleasures of success, of companionship, and so on. This being so, it is easy for imagination to call up a semblance of these higher feelings. Since they depend largely on representation, a mere act of representation may suffice to excite a degree of the feeling hardly distinguishable from the actual one. Thus, to imagine myself as contented is really to see myself at the moment as actually contented. Again, the actor, tho . . . he does not feel all that the spectator is apt to attribute to him, tends, when vividly representing to himself a particular shade of feeling, to regard himself as actually feeling in this way. Thus, it is said of Garrick, that when acting Richard III, he felt himself for the moment to be a villain.—SULLY *Illusions*, ch. 8, p. 199. (A., 1897.)

1579. IMAGINATION, POETIC, OF GREAT DISCOVERER — *Scientific Insight Penetrates the Unknown—Columbus Infers a Continent—Orinoco Thought a River of Paradise*—The appearance of this region [near the mouth of the Orinoco] first convinced the bold navigator Columbus of the existence of an American continent. "Such an enormous body of fresh water," concluded this acute observer of Nature, "could only be collected from a river having a long course; the land, therefore, which supplied it must be a continent and not an island." As, according to Arrian, the companions of Alexander, when they penetrated across the snow-crowned summits of Paropamisus, believed that they recognized in the crocodile-teeming Indus a part of the Nile, so Columbus, in his ignorance of the similarity of physiognomy which characterizes all the products of the climate of palms, imagined that the new continent was the eastern coast of the far-projecting Asia. The grateful coolness of the evening air, the ethereal purity of the starry firmament, the balmy fragrance of flowers, wafted to him by the land breeze—all led him to suppose (as we are told by Herrera, in the "Decades") that he was approaching the Garden of Eden, the sacred abode of our first parents. The Orinoco seemed to him one of the four rivers which, according to the venerable tradition of the ancient world, flowed from Paradise to water and divide the surface of the earth,

newly adorned with plants. This poetical passage in the Journal of Columbus, or rather in a letter to Ferdinand and Isabella, written from Haiti in October, 1498, presents a peculiar psychological interest. It teaches us anew that the creative fancy of the poet manifests itself in the discoverer of a world no less than in every other form of human greatness.—HUMBOLDT *Views of Nature*, p. 155. (Bell, 1896.)

1580. IMAGINATION PRODUCING FAINTNESS—"A clergyman told me that some time ago suspicions were entertained in his parish of a woman who was supposed to have poisoned her newly-born infant. The coffin was exhumed, and the procurator-fiscal, who attended with the medical men to examine the body, declared that he already perceived the odor of decomposition, which made him feel faint, and in consequence he withdrew. But on opening the coffin it was found to be empty, and it was afterwards ascertained that no child had been born, and consequently no murder committed."—BENNET quoted by CARPENTER in *Nature and Man*, bk. i, ch. 4, p. 158. (A., 1900.)

1581. IMAGINATION STIMULATED BY STUDY OF NATURE—*Sublimity of a Tropical Night.*—If I might be allowed to abandon myself to the recollections of my own distant travels I would instance, among the most striking scenes of Nature, the calm sublimity of a tropical night when the stars, not sparkling as in our northern skies, shed their soft and planetary light over the gently heaving ocean, or I would recall the deep valleys of the Cordilleras, where the tall and slender palms pierce the leafy veil around them, and waving on high their feathery and arrow-like branches, form, as it were, "a forest above a forest"; or I would describe the summit of the peak of Teneriffe when a horizontal layer of clouds, dazzling in whiteness, has separated the cone of cinders from the plain below, and suddenly the ascending current pierces the cloudy veil, so that the eye of the traveler may range from the brink of the crater, along the vine-clad slopes of Orotava, to the orange-gardens and banana-groves that skirt the shore. In scenes like these it is not the peaceful charm uniformly spread over the face of Nature that moves the heart, but rather the peculiar physiognomy and conformation of the land, the features of the landscape, the ever-varying outline of the clouds, and their blending with the horizon of the sea, whether it lies spread before us like a smooth and shining mirror or is dimly seen through the morning mist. All that the senses can but imperfectly comprehend, all that is most awful in such romantic scenes of Nature, may become a source of enjoyment to man, by opening a wide field to the creative powers of his imagination. Impressions change with the varying movements of the mind, and we are led by a happy illusion to believe that we receive from the external world that with which we have ourselves invested it.—HUMBOLDT *Cosmos*, vol. i, int., p. 26. (H., 1897.)

1582. IMITATION A CONTROLLING HUMAN IMPULSE—*Civilization Founded upon It.*—The instinct of imitating gestures develops earlier than that of imitating sounds [and] usually falls well inside the limits of the first year. Later come all the various imitative games in which childhood revels, playing "horse," "soldiers," etc., etc. And from this time onward man is essentially the imitative animal. His whole educability and in fact the whole history of civilization depend on this trait, which his strong tendencies to rivalry, jealousy, and acquisitiveness reenforce. "*Humani nihil a me alienum puto*" is the motto of each individual of the species, and makes him, whenever another individual shows a power or superiority of any kind, restless until he can exhibit it himself. . . . And there is the imitative tendency which shows itself in large masses of men, and produces panics and orgies and frenzies of violence, and which only the rarest individuals can actively withstand. This sort of imitativeness is possessed by man in common with other gregarious animals, and is an instinct in the fullest sense of the term, being a blind impulse to act as soon as a certain perception occurs. It is particularly hard not to imitate gaping, laughing, or looking and running in a certain direction if we see others doing so. Certain mesmerized subjects must automatically imitate whatever motion their operator makes before their eyes. A successful piece of mimicry gives to both bystanders and mimic a peculiar kind of esthetic pleasure.—JAMES *Psychology*, vol. ii, ch. 24, p. 408. (H. H. & Co., 1899.)

1583. IMITATION INSTINCTIVE AND UNIVERSAL—*The Chief Element in the Learning of Language.*—From the first days of life we are surrounded by our fellow men and imitate their actions. And these mimetic movements are instinctive in character. As soon as the child's consciousness is aroused from its first sleepy passivity, it begins to perceive the expressions of others' emotions, and to respond to them by similar emotions with corresponding impulses. The continued imitation by which a child comes to learn the language that is spoken round it is impulsive, not voluntary.—WUNDT *Psychology*, lect. 27, § 1, p. 396. (Son. & Co., 1896.)

1584. IMITATION SECURES THE CONTINUITY OF RACIAL LIFE—*Social Heredity.*—Man has always been recognized as the imitative animal *par excellence*. And there is hardly a book on psychology, however old, which has not devoted at least one paragraph to this fact. . . . Each of us is in fact what he is almost exclusively

by virtue of his imitativeness. We become conscious of what we ourselves are by imitating others—the consciousness of what the others are precedes—the sense of self grows by the sense of pattern. The entire accumulated wealth of mankind—languages, arts, institutions, and sciences—is passed on from one generation to another by what Baldwin has called social heredity, each generation simply imitating the last. . . . Invention, using the term most broadly, and imitation are the two legs, so to call them, on which the human race historically has walked.—JAMES *Talks to Teachers*, ch. 7, p. 48. (H. H. & Co., 1900.)

1585. IMMIGRATION OF ANIMALS FROM SHALLOW WATER TO THE DEEP SEA—*Gradual Adaptation to Their New Home.*—Nor can we consider for a moment that the abyss was the original source of the shallow-water fauna; for not only do we find but few types that can be considered to be, in any sense of the word, ancestral in character, but on the contrary most of the animals of the deep sea seem to be specially modified types of shallow-water forms. The most probable explanation of the origin of the deep-sea fauna is the one that was put forward by Moseley and has been since supported by almost every authority on the subject, namely, that the fauna of the deep sea has been derived from successive immigrations of the animals from the shallow water.—HICKSON *Fauna of the Deep Sea*, ch. 3, p. 54. (A., 1894.)

1586. IMMORTALITY OF GRATEFUL REMEMBRANCE A SHAM—*Delusion of Positivism.*—The positivist argument that the only worthy immortality is survival in the grateful remembrance of one's fellow creatures would hardly be regarded as anything but a travesty and trick. If the world's long-cherished beliefs are to fall, in God's name let them fall, but save us from the intellectual hypocrisy that goes about pretending we are none the poorer!—FISKE *Through Nature to God*, pt. iii, ch. 5, p. 170. (H. M. & Co., 1900.)

1587. IMMORTALITY, RACIAL, A DELUSIVE HOPE—*The Moon a Dead World—Perhaps a Cemetery.*—The moon, then, is dead; and if it ever was the home of a race like ours that race is dead, too. I have said that our New Astronomy modifies our view of the moral universe as well as of the physical one; nor do we need a more pregnant instance than in this before us. In these days of decay of old creeds of the eternal, it has been sought to satisfy man's yearning toward it by founding a new religion whose god is humanity, and whose hope lies in the future existence of our own race, in whose collective being the individual who must die may fancy his aims and purpose perpetuated in an endless progress. But, alas for hopes looking to this alone! we are here brought to face the solemn thought that, like the individual, tho at a little further date, humanity itself may die!—LANGLEY *New Astronomy*, ch. 5, p. 171. (H. M. & Co., 1896.)

1588. IMMUNITY, NATURAL, OF SOME PERSONS AND RACES—*Relative Immunity of Children and Adults—Plague and Leprosy Rare in English Race.*—The term "natural immunity" is used to denote natural resistance to some particular specific disease. It may refer to race, or age, or individual idiosyncrasies. We not infrequently meet with examples of this freedom from disease. Certain races of men do not, as a rule, take certain diseases. For example, plague and leprosy, tho epidemic in some countries, fail to get a footing in England. This, of course, is due in great measure to the sanitary organization and cleanly customs of the English people. Still, it is also due to the fact that the English appear in some degree to be immune. Some authorities hold that the immunity against leprosy is due to the fact that the disease has exhausted itself in the English race. However that may be, we know that immunity, entire or partial, exists. Children, again, are susceptible to certain diseases and insusceptible to certain others to which older people are susceptible. We know, too, that some individuals have a marked protection against some diseases. Some people coming into the way of infection at once fall victims to the disease, whilst others appear to be proof against it.—NEWMAN *Bacteria*, ch. 7, p. 240. (G. P. P., 1899.)

1589. IMPERFECTION OF HUMAN SENSES—*Dependence on Speed of Light—Only the Past of the Stars Known—And That in Fragments—Gravity Would Be a Swifter Messenger.*—We learn by a view of the heavens that twenty years ago Sirius was shining with such and such brightness; that a hundred years ago some other star was shining with its degree of luster, and so on; but the star depths are never revealed to us exactly as they are at the moment, or exactly as they were at any moment. Yet this is merely due to the imperfection of our senses. We judge by the light of these objects, and this light travels at such and such a rate. It is conceivable that creatures might have a sense enabling them to judge by some other form of action, exerted by the stars, as for instance by the action of gravity. If gravity were the action thus effective, the information conveyed respecting the universe would be far more nearly contemporaneous, since the action of gravity certainly travels many thousands of times faster than light, even if it do not travel with infinite velocity as some philosophers suppose.—PROCTOR *Expanse of Heaven*, p. 207. (L. G. & Co., 1897.)

1590. IMPERFECTION OF INSTRUMENTS—*Diffusion of Light Weakens Optical Image in Giant Telescope—Atmospheric Hindrances.*—Lord Rosse's telescope possesses a nominal power of 6,000—that is,

it shows the moon as if viewed with the naked eye at a distance of forty miles. But this seeming advantage is neutralized by the weakening of the available light through excessive diffusion, as well as by the troubles of the surging sea of air through which the observation must necessarily be made. Professor Newcomb, in fact, doubts whether with *any* telescope our satellite has ever been seen to such advantage as it would be if brought within 500 miles of the unarmed eye.—CLERKE *History of Astronomy*, pt. i, ch. 6, p. 148. (Bl., 1893.)

1591. IMPERFECTION OF THE GEOLOGICAL RECORD—*Destructive Agencies Obliterate the Remains.*—It can be demonstrated that the geological record must be incomplete, that it can only preserve remains found in certain favorable localities and under particular conditions; that it must be destroyed by processes of denudation, and obliterated by processes of metamorphosis. Beds of rock of any thickness, crammed full of organic remains, may yet, either by the percolation of water through them or by the influence of subterranean heat, lose all trace of these remains, and present the appearance of beds of rock formed under conditions in which living forms were absent. Such metamorphic rocks occur in formations of all ages; and in various cases there are very good grounds for the belief that they have contained organic remains, and that those remains have been absolutely obliterated.—HUXLEY *American Addresses*, lect. 2, p. 42. (A., 1898.)

1592. IMPERFECTIONS OF THE EYE—*Yet a Marvel to the Reflecting Mind.*—And here, in passing, I am reminded of the common delusion that the works of Nature, the human eye included, are theoretically perfect. The eye has grown for ages towards perfection; but ages of perfecting may be still before it. . . . A long list of indictments might indeed be brought against the eye—its opacity, its want of symmetry, its lack of achromatism, its absolute blindness, in part. All these taken together caused Helmholtz to say that if any optician sent him an instrument so full of defects he would be justified in sending it back with the severest censure. But the eye is not to be judged from the standpoint of theory. It is not perfect, as I have said, but on its way to perfection. As a practical instrument, and taking the adjustments by which its defects are neutralized into account, it must ever remain a marvel to the reflecting mind.—TYNDALL *Lectures on Light*, lect. 1, p. 8. (A., 1898.)

1593. IMPERIOUSNESS OF WRONG HABIT—*Student Revisiting Paris Unconsciously Seeks Old Room.*—Not only is it the right thing at the right time that we thus involuntarily do [when a habit has become fixed], but the wrong thing also, if it be an habitual thing. Who is there that has never wound up his watch on taking off his waistcoat in the daytime, or taken his latch-key out on arriving at the door-step of a friend? Very absent-minded persons in going to their bedroom to dress for dinner have been known to take off one garment after another and finally to get into bed, merely because that was the habitual issue of the first few movements when performed at a later hour. The writer well remembers how, on revisiting Paris after ten years' absence, and finding himself in the street in which for one winter he had attended school, he lost himself in a brown study, from which he was awakened by finding himself upon the stairs which led to the apartment in a house many streets away in which he had lived during that earlier time, and to which his steps from the school had then habitually led.—JAMES *Psychology*, vol. i, ch. 4, p. 114. (H. H. & Co., 1899.)

1594. IMPERSONATION—*The Dramatic Impulse Strong in Children.*—The dramatic impulse, the tendency to pretend one is some one else, contains this pleasure of mimicry as one of its elements. Another element seems to be a peculiar sense of power in stretching one's own personality so as to include that of a strange person. In young children this instinct often knows no bounds. For a few months in one of my children's third year, he literally hardly ever appeared in his own person. It was always, "Play I am So-and-so, and you are So-and-so, and the chair is such a thing, and then we'll do this or that." If you called him by his name, H., you invariably got the reply, "I'm not H., I'm a hyena, or a horse-car," or whatever the feigned object might be. He outwore this impulse after a time; but while it lasted it had every appearance of being the automatic result of ideas, often suggested by perceptions, working out irresistible motor effects.—JAMES *Psychology*, vol. ii, ch. 24, p. 409. (H. H. & Co., 1899.)

1595. IMPERSONATION CREATING MYTHS—*Origin of the Three Fates—Past, Present, Future.*—Another well-known mythic group shows again how what to us moderns are but ideas expressed in words, took personal form in the minds of the ancients. In the classic books of Greece and Rome we read of the three fate-spinners, the Moirai or Parcæ, and their Scandinavian counterparts appear in the Edda as the three wise women whose dwelling is near the spring under the world-ash Ygdrasill, the Norns who fix the lives of men. The explanation of these three mythic beings is that they are in personal shape the Past, Present, and Future, as is shown by the names they bear—Was, Is, Shall (Urdhr, Verdhandi, Skuld).—TYLOR *Anthropology*, ch. 15, p. 396. (A., 1899.)

1596. IMPLEMENTS, NATURAL, EFFECTIVENESS OF—*Bill of Macaw Surpasses Hammer—Hardest Nuts Crushed to*

Pulp.—We saw here, for the first time, the splendid hyacinthine macaw *(Macrocercus hyacinthinus*, Lath., the *araruna* of the natives), one of the finest and rarest species of the parrot family. It only occurs in the interior of Brazil, from 16° S. lat. to the southern border of the Amazons Valley. It is three feet long from the beak to the tip of the tail, and is entirely of a soft hyacinthine blue color, except round the eyes, where the skin is naked and white. It flies in pairs, and feeds on the hard nuts of several palms, but especially of the "mucuja" *(Acrocomia lasiospatha)*. These nuts, which are so hard as to be difficult to break with a heavy hammer, are crushed to a pulp by the powerful beak of this macaw.—BATES *Naturalist on the River Amazon*, ch. 4, p. 649. (Hum., 1880.)

1597. IMPOSTURE PRACTISED BY COWBIRD—We often see these birds feeding near cattle in the pastures, always in small flocks, for they do not pair nor even construct a nest, the female laying her egg in the nest of another and generally smaller species. Few birds seem aware of the imposture, and not only do they incubate the egg, but they may attend to the demands of the young cowbird at the expense of their own offspring, who sometimes die of starvation. Even after leaving the nest the young parasite continues its call for food, and when seeing a Maryland yellowthroat or some other small bird feeding a clumsy fledgling twice its size, one wonders it does not detect the deception.—CHAPMAN *Bird-Life*, ch. 7, p. 174. (A., 1900.)

1598. IMPRESSION ON PREPARED NERVE-CENTER—*Apperception—The Lover's Tap—The Friend's Voice.*—This reenforcement of ideas and impressions by the preexisting contents of the mind was what Herbart had in mind when he gave the name of "apperceptive attention" to the variety we describe. We easily see now why the lover's tap should be heard—it finds a nerve-center half ready in advance to explode. We see how we can attend to a companion's voice in the midst of noises which pass unnoticed tho objectively much louder than the words we hear. Each word is doubly awakened; once from without by the lips of the talker, but already before that from within by the premonitory processes irradiating from the previous words, and by the dim arousal of all processes that are connected with the "topic" of the talk. The irrelevant noises, on the other hand, are awakened only once. They form an unconnected train. The boys at school, inattentive to the teacher except when he begins an anecdote, and then all pricking up their ears, are as easily explained. The words of the anecdote shoot into association with exciting objects which react and fix them; the other words do not.—JAMES *Psychology*, vol. i, ch. 11, p. 450. (H. H. & Co., 1899.)

1599. IMPRESSION, WEAK, OBLITERATED BY STRONG—*Tick of Clock—Light of Stars—Slight Weight Added to Heavier Weight.*—Every one knows that in the stillness of night we hear things which are unperceived in the noise of day. The gentle ticking of the clock, the distant bustle of the streets, the creaking of the chairs in the room, impress themselves upon our ear. And every one knows that amid the confused hubbub of the market-place or the roar of a railway-train we may lose what our neighbor is saying to us, or even fail to hear our own voice. . . . The tick of the clock is a weak stimulus for our auditory nerves, which we hear plainly when it is given by itself, but not when it is added to a strong stimulus of rattling wheels and all the other turmoil. The light of the stars is a stimulus for the eye; but if its stimulation is added to the strong stimulus of daylight, we do not notice it, altho we sense it clearly when it is joined to the weak stimulus of twilight. The gram weight is a stimulus for our skin which we sense when it is united to a present stimulus of equal strength, but which vanishes when it is combined with a stimulus of a thousand times its own intensity.—WUNDT *Psychology*, lect. 2, p. 22. (Son. & Co., 1896.)

1600. IMPRESSIONS OF CHILDHOOD A STIMULUS TO SCIENTIFIC PURSUITS—*Stories of Adventure Combine with Love of Science.*—The longing wish I felt to behold the Pacific from the lofty ridges of the Andes was mingled with recollections of the interest with which, as a boy, I had dwelt on the narrative of the adventurous expedition of Vasco Nuñez de Balboa. That happy man, whose track Pizarro followed, was the first to behold, from the heights of Quarequa, on the Isthmus of Panama, the eastern part of the great "South Sea." The reedy shores of the Caspian, viewed from the point whence I first beheld them, viz., from the delta formed by the mouths of the Volga, cannot certainly be called picturesque, yet the delight I felt on first beholding them was enhanced by the recollection that, in my very earliest childhood, I had been taught to observe, on the map, the form of the Asiatic inland sea. The impressions aroused within us in early childhood, or excited by the accidental circumstances of life, frequently, in after-years, take a graver direction, and become stimulants to scientific labors and great enterprises.—HUMBOLDT *Views of Nature*, p. 417. (Bell, 1896.)

1601. IMPRINT OF RAIN-DROPS—*Enduring Record of the Evanescent.*—When a shower of rain falls, the highest portion of the mud-covered flat is usually too hard to receive any impressions; while that recently uncovered by the tide near the water's edge is too soft. Between these areas a zone occurs, almost as smooth and even as a looking-glass, on which every drop forms a cavity of circular or oval form,

and, if the shower be transient, these pits retain their shape permanently, being dried by the sun, and being then too firm to be effaced by the action of the succeeding tide, which deposits upon them a new layer of mud. Hence we often find, in splitting open a slab an inch or more thick, on the upper surface of which the marks of recent rain occur, that an inferior layer, deposited during some previous rise of the tide, exhibits on its under side perfect casts of rain-prints, which stand out in relief, the molds of the same being seen on the layer below.—LYELL *Principles of Geology*, bk. ii, ch. 14, p. 202. (A., 1854.)

1602. IMPROVEMENT CEASES WITH LACK OF COMPETITION—*The Humming-bird Has No Rival in Its Own Field.*—It is perhaps a law of Nature that when a species (or group) fits itself to a place not previously occupied, and in which it is subject to no opposition from beings of its own class, or where it attains so great a perfection as to be able easily to overcome all opposition, the character eventually loses its original plasticity, or tendency to vary, since improvement in such a case would be superfluous, and becomes, so to speak, crystallized in that form which continues thereafter unaltered. It is, at any rate, clear that while all other birds rub together in the struggle for existence, the humming-bird, owing to its aerial life and peculiar manner of seeking its food, is absolutely untouched by this kind of warfare, and is accordingly as far removed from all competition with other birds as the solitary savage is removed from the struggle of life affecting and modifying men in crowded communities. The lower kind of competition affecting humming-birds, that with insects, and, within the family, of species with species, has probably only served to intensify their unique characteristics, and, perhaps, to lower their intelligence.—HUDSON *Naturalist in La Plata*, ch. 16, p. 217. (C. & H., 1895.)

1603. IMPULSE FOR HABITUAL MOVEMENT SUPPLIED BY LAST PRECEDING MOVEMENT—In action grown habitual, what instigates each new muscular contraction to take place in its appointed order is not a thought or a perception, but the sensation occasioned by the muscular contraction just finished. A strictly voluntary act has to be guided by idea, perception, and volition, throughout its whole course. In an habitual action, mere sensation is a sufficient guide, and the upper regions of the brain and mind are set comparatively free.—JAMES *Psychology*, vol. i, ch. 4, p. 115. (H. H. & Co., 1899.)

1604. IMPULSE, MIGRATORY, IN CAGE-BIRDS—*Desertion of Young by Mother-birds—An Instinct Stronger than Maternal Affection.*—Nearly every bird is, indeed, more or less migratory; that is, it changes its quarter to a certain extent according to the season of the year. Even cage-birds, reared from the eggs of parents who never knew what freedom was, get as uneasy as a Londoner in August, and if their prison-doors are left open will sometimes desert their helpless young in order not to be too late for the winter hegira. The house-martin has been known to do so repeatedly; and if the autumn is colder than usual, the swallow and the Carolina waxwing will suddenly take their departure from Canada, leaving their callow brood to die of starvation, the instinct of self-preservation being evidently stronger than that of maternal affection.—BROWN *Nature-Studies*, p. 14. (Hum., 1888.)

1605. IMPULSE TO ACQUISITION—*Loss Involves Seeming Shrinkage of Ourselves.*—An . . . instinctive impulse drives us to collect property; and the collections thus made become, with different degrees of intimacy, parts of our empirical selves. The parts of our wealth most intimately ours are those which are saturated with our labor. There are few men who would not feel personally annihilated if a lifelong construction of their hands or brains—say an entomological collection or an extensive work in manuscript—were suddenly swept away. The miser feels similarly towards his gold, and altho it is true that a part of our depression at the loss of possessions is due to our feeling that we must now go without certain goods that we expected the possessions to bring in their train, yet in every case there remains, over and above this, a sense of the shrinkage of our personality, a partial conversion of ourselves to nothingness, which is a psychological phenomenon by itself. We are all at once assimilated to the tramps and poor devils whom we so despise, and at the same time remove farther than ever away from the happy sons of earth who lord it over land and sea and men in the full-blown lustihood that wealth and power can give, and before whom, stiffen ourselves as we will by appealing to anti-snobbish first principles, we cannot escape an emotion, open or sneaking, of respect and dread.—JAMES *Psychology*, vol. i, ch. 10, p. 293. (H. H. & Co., 1899.)

1606. IMPULSES RIPEN SUCCESSIVELY—*The Flowering-time an Opportunity To Be Seized.*—In children we observe a ripening of impulses and interests in a certain determinate order. Creeping, walking, climbing, imitating vocal sounds, constructing, drawing, calculating, possess the child in succession; and in some children the possession, while it lasts, may be of a semi-frantic and exclusive sort. Later, the interest in any one of these things may wholly fade away. Of course, the proper pedagogic moment to work skill in, and to clench the useful habit, is when the native impulse is most acutely present. Crowd on the athletic opportunities, the mental arithmetic, the verse-learning, the drawing, the botany,

or what not, the moment you have reason to think the hour is ripe. The hour may not last long, and while it continues you may safely let all the child's other occupations take a second place. In this way you economize time and deepen skill; for many an infant prodigy, artistic or mathematical, has a flowering epoch of but a few months. —JAMES *Talks to Teachers,* ch. 7, p. 61. (H. H. & Co., 1900.)

1607. IMPURITIES REJECTED BY GLACIER—*Popular Belief Founded on Scientific Fact.*—A notion [has been] long entertained by the inhabitants of the high Alps, that glaciers possess the power of thrusting out all impurities from them. On the Mer de Glace I have noticed large patches of clay and black mud which evidently came from the body of the glacier, and can therefore understand how natural was this notion of extrusion to people unaccustomed to close observation. But the power of the glacier in this respect is in reality the power of the sun, which fuses the ice above concealed impurities, and, like the bodies of the guides on the Glacier des Bossons, brings them to the light of day.—TYNDALL *Forms of Water,* p. 144. (A., 1899.)

1608. IMPURITY OF NATURAL COLORS—*Green Leaves Seen Red and Blue.*—The impurity of natural colors is strikingly illustrated by an observation recently communicated to me by Mr. Woodbury. On looking through a blue glass at green leaves in sunshine, he saw the superficially reflected light, blue. The light, on the contrary, which came from the body of the leaves was crimson. On examination, I found that the glass employed in this observation transmitted both ends of the spectrum, the red as well as the blue, and that it quenched the middle. This furnished an easy explanation of the effect. In the delicate spring foliage the blue of the solar light is for the most part absorbed, and a light, mainly yellowish green, but containing a considerable quantity of red, escapes from the leaf to the eye. On looking at such foliage through the violet glass, the green and the yellow are stopped, and the red alone reaches the eye. Thus regarded, therefore, the leaves appear like faintly blushing roses, and present a very beautiful appearance. With the blue ammonia-sulfate of copper, which transmits no red, this effect is not obtained. As the year advances the crimson gradually hardens to a coppery red; and in the dark-green leaves of old ivy it is almost absent. Permitting a concentrated beam of white light to fall upon fresh leaves in a dark room, the sudden change from green to red, and from red back to green, when the violet glass is alternately introduced across the beam and withdrawn, is very surprising. Looked at through the same glass, the meadows in May appear of a warm purple.—TYNDALL *Lectures on Light,* lect. 1, p. 38. (A., 1898.)

1609. INATTENTION TO THE UNIMPORTANT—*Habitual Sensations Ignored—Din of Foundry Unnoticed by Its Workers.*—We do not notice the ticking of the clock, the noise of the city streets, or the roaring of the brook near the house; and even the din of a foundry or factory will not mingle with the thoughts of its workers, if they have been there long enough. When we first put on spectacles, especially if they be of certain curvatures, the bright reflections they give of the windows, etc., mixing with the field of view, are very disturbing. In a few days we ignore them altogether. Various entoptic images, *muscæ volitantes* [flitting specks before the eyes], etc., altho constantly present, are hardly ever known. The pressure of our clothes and shoes, the beating of our hearts and arteries, our breathing, certain stedfast bodily pains, habitual odors, tastes in the mouth, etc., are examples from other senses of the same lapse into unconsciousness of any too unchanging content—a lapse which Hobbes has expressed in the well-known phrase, "*Semper idem sentire ac non sentire ad idem revertunt*" [To feel always and not to feel at all come to the same thing].—JAMES *Psychology,* vol. i, ch. 11, p. 455. (H. H. & Co., 1899.)

1610. INCANDESCENCE, COLORS OF, NO PICTURE CAN REPRESENT—*Splendor of Sun's Corona Defies Artist's Skill.*—Pictures are sometimes drawn which attempt to show the color of these [solar] flames. Some of these have been made at the Observatory of Harvard College, United States, where these phenomena are observed with the greatest care. On one of these plates two magnificent prominences of more than 60,000 miles in height are shown, the first observed on April 29, 1872, at 10 o'clock in the morning (25 minutes later it had so much changed that it was not to be recognized); the second, on April 15 of the same year, at the same hour. We may thus gain a better impression of them than by black figures. But there is something which a picture can never reproduce—the vivacity of the tints which these enormous masses present, and the rapidity of the motions with which they are animated. The best drawings will always be bodies without life, veritable corpses, if we compare them with the grand phenomena of Nature. These incandescent masses are animated with an internal activity, from which life seems to breathe. They shine with a vivid light, and the colors which adorn them form a specific character, by which we can recognize, thanks to spectrum analysis, the chemical nature of the substances which compose them. Could the most perfect drawings depict this solar life?—FLAMMARION *Popular Astronomy,* bk. iii, ch. 4, p. 275. (A.)

1611. INCANDESCENCE, PHENOMENA OF—*Black Bodies Emit Most Intense Light.*—We have employed as our source of

light in these lectures the ends of two rods of coke, rendered incandescent by electricity. Coke is particularly suitable for this purpose, because it can bear intense heat without fusion or vaporization. It is also black, which helps the light; for other circumstances being equal, as shown experimentally by Professor Balfour Stewart, the blacker the body the brighter will be its light when incandescent.—TYNDALL *Lectures on Light*, lect. 6, p. 192. (A., 1898.)

1612. INCLUSION VS. EXCLUSION—*Value of Each in Scientific Research—Newton United Caution and Intrepidity.*—He [Sir Isaac Newton] wanted no other recommendation for any one article of science than the recommendation of evidence—and, with this recommendation, he opened to it the chamber of his mind, tho authority scowled upon it, and taste was disgusted by it, and fashion was ashamed of it, and all the beauteous speculation of former days was cruelly broken up by this new announcement of the better philosophy, and scattered like the fragments of an aerial vision, over which the past generations of the world had been slumbering their profound and their pleasing reverie. But, on the other hand, should the article of science want the recommendation of evidence, he shut against it all the avenues of his understanding, and tho all antiquity lent their suffrages to it, and all eloquence had thrown around it the most attractive brilliancy, and all habit had incorporated it with every system of every seminary in Europe, and all fancy had arrayed it in graces of the most tempting solicitation, yet was the steady and inflexible mind of Newton proof against this whole weight of authority and allurement, and, casting his cold and unwelcome look at the specious plausibility, he rebuked it from his presence. The strength of his philosophy lay as much in refusing admittance to that which wanted evidence as in giving a place and an occupancy to that which possessed it.—CHALMERS *Astronomical Discourses*, p. 48. (R. Ct., 48.)

1613. INCOMPATIBILITY OF MENTAL QUALITIES—*Activity vs. Sensibility—Intellect vs. Emotion—Each Form of Greatness Has Its Own Sphere.*—Great activity and great sensibility are extreme phases, each using a large amount of power, and therefore scarcely to be coupled in the same system. The active, energetic man, loving activity for its own sake, moving in every direction, wants the delicate circumspection of another man who does not love activity for its own sake, but is energetic only at the spur of his special ends. And, once more, great intellect as a whole is not readily united with a large emotional nature. The incompatibility is best seen by inquiring whether men of overflowing sociability are deep and original thinkers, great discoverers, accurate inquirers, great organizers in affairs, or whether their greatness is not limited to the spheres where feeling performs a part—poetry, eloquence and social ascendency.—BAIN appendix to *Conservation of Energy* by STEWART, p. 431. (Hum.)

1614. INCREASE BY DESTRUCTION—*Gas Weighs More than the Coal Producing It.*—A large part of the structure of the earth's crust is formed of a substance called limestone. Ordinary limestone is a compound of common lime and carbon dioxid, a gas that is found mixed with the air to a very small degree. Carbon dioxid will be better known by the older people as carbonic acid. It is a gas that is given off whenever wood and coal are burned, or any substance containing carbon. It is composed of one atom of carbon to two of oxygen. Every ton of carbon that is burned sends off three and two-thirds tons of this gas. The increase in weight comes from the fact that every atom of carbon unites with two of oxygen, which it takes from the air, and the oxygen is heavier than the carbon. In comparing the relative weights of atoms (the smallest combinable particle of a solid, liquid, or gas) we use the hydrogen atom as the unit of comparison and call it "one," because it is the lightest of all atoms. The carbon atom is twelve times and the oxygen atom sixteen times as heavy as the hydrogen atom. Hence it will be seen readily how a ton of carbon will form three and two-thirds times its weight of carbon dioxid. Lime, having a strong affinity or attraction for this gas, has absorbed it from the air and water, forming what is known as carbonate of lime, which is the ordinary limestone.—ELISHA GRAY *Nature's Miracles*, vol. i, ch. 2, p. 12. (F. H. & H., 1900.)

1615. INCREASE OF ANIMALS UNDER PROTECTION—*The South-American Coypú—Change of Habits—Sudden Extermination.*—The coypú was much more abundant fifty years ago than now, and its skin, which has a fine fur under the long coarse hair, was largely exported to Europe. About that time the dictator Rosas issued a decree prohibiting the hunting of the coypú. The result was that the animals increased and multiplied exceedingly, and abandoning their aquatic habits they became terrestrial and migratory, and swarmed everywhere in search of food. Suddenly a mysterious malady fell on them, from which they quickly perished, and became almost extinct.—HUDSON *Naturalist in La Plata*, ch. 1, p. 12. (C. & H., 1895.)

1616. INCREASE OF EUROPEAN CATTLE IN THE NEW WORLD—Columbus, in his second voyage, left a few black cattle at Santo Domingo, and these ran wild and increased so much that twenty-seven years afterwards herds of from 4,000 to 8,000 head were not uncommon. Cattle were afterwards taken from this island to Mexico and to other parts of America, and in 1587, sixty-five years after the conquest of Mexico,

the Spaniards exported 64,350 hides from that country and 35,444 from Santo Domingo, an indication of the vast numbers of these animals which must then have existed there, since those captured and killed could have been only a small portion of the whole.—WALLACE *Darwinism*, ch. 2, p. 18. (Hum., 1889.)

1617. INCREASE OF HEAT FROM VIOLET TO RED AND BEYOND—Throwing a small and concentrated spectrum upon a screen, by means of an endless screw we move [a thermopile] . . . through the entire spectrum, and determine in succession the thermal power of all its colors. When this instrument is brought to the violet end of the spectrum the heat is found to be almost insensible. As the pile gradually moves from the violet towards the red, it encounters a gradually augmenting heat. The red itself possesses the highest heating power of all the colors of the spectrum. Pushing the pile into the dark space beyond the red, the heat rises suddenly in intensity, and at some distance beyond the red it attains a maximum. From this point the heat falls somewhat more rapidly than it rose, and afterwards gradually fades away. —TYNDALL *Lectures on Light*, lect. 5, p. 189. (A., 1898.)

1618. INCREASE OF SURFACE IN LUNG—*Device of the Diaphragm—Respiratory Power in Small Compass.*—In the lung of man, as of mammals generally, an extraordinary increase is given to the extent of aerating surface, by the excessively minute subdivision of the cavity into air-cells, of which thousands are clustered round the end of each terminal twig of the bronchial tree. But this increase would be without effect if there were not at the same time a most elaborate provision in the skeleton of the trunk, in the disposition of its muscles, and in the mode in which these are acted on by the nervous apparatus, for alternately filling and emptying the lungs, so as to take in fresh supplies of oxygen for the aeration of the blood, and to get rid of the carbonic acid which it gives off. The chief feature in this provision is the enclosure of the lungs in a distinct cavity (that of the chest) cut off from the abdomen by a muscular partition, the diaphragm, the contraction of which, by increasing the capacity of the chest, produces an inrush of air down the air-passages, which penetrates to the remotest parts of the minutely subdivided cavity of the lungs. By no other action could the air contained in that cavity be so effectually renewed. Thus the pulmonary apparatus of the mammal is the most perfect form that could be devised for obtaining the highest amount of respiratory power within the smallest compass.—CARPENTER *Nature and Man*, lect. 15, p. 461. (A., 1889.)

1619. INCREASE, SIMULTANEOUS, OF HUMBLEBEES AND MICE—*Fowls Made Rapacious Mousers.*—In the summer of 1872-73 we had plenty of sunshine, with frequent showers, so that the hot months brought no dearth of wild flowers, as in most years. The abundance of flowers resulted in a wonderful increase of humblebees. I have never known them so plentiful before; in and about the plantation adjoining my house I found during the season no fewer than seventeen nests. The season was also favorable for mice—that is, of course, favorable for the time being, unfavorable in the long run, since the short-lived, undue preponderance of a species is invariably followed by a long period of undue depression. These prolific little creatures were soon so abundant that the dogs subsisted almost exclusively on them; the fowls also, from incessantly pursuing and killing them, became quite rapacious in their manner, whilst the sulfur tyrant-birds *(Pitangus)* and the Guira cuckoos preyed on nothing but mice.—HUDSON *Naturalist in La Plata*, ch. 3, p. 59. (C. & H., 1895.)

1620. INCREASE, VAST POSSIBLE, OF BIRDS—*Vast Consequent Destruction—Slaughter Unperceived.*—Let us now consider a less extreme and more familiar case. We possess a considerable number of birds which, like the redbreast, sparrow, the four common titmice, the thrush, and the blackbird, stay with us all the year round. These lay on an average six eggs, but as several of them have two or more broods a year ten will be below the average of the year's increase. Such birds as these often live from fifteen to twenty years in confinement, and we cannot suppose them to live shorter lives in a state of nature, if unmolested: but to avoid possible exaggeration we will take only ten years as the average duration of their lives. Now, if we start with a single pair, and these are allowed to live and breed, unmolested, till they die at the end of ten years, . . . their numbers would amount to more than twenty millions. But we know very well that our bird population is no greater, on the average, now than it was ten years ago. . . . What, then, becomes of the enormous surplus population annually produced? It is evident they must all die or be killed, somehow; and as the increase is, on the average, about five to one, it follows that if the average number of birds of all kinds in our islands is taken at ten millions—and this is probably far under the mark—then about fifty millions of birds, including eggs as possible birds, must annually die or be destroyed. Yet we see nothing, or almost nothing, of this tremendous slaughter of the innocents going on all around us.—WALLACE *Darwinism*, ch. 2, p. 17. (Hum., 1889.)

1621. INCREDULITY HINDERS INVESTIGATION—*All Evidence of Meteorites Once Rejected.*—That arrogant spirit of incredulity which rejects facts without attempting to investigate them is in some cases almost more injurious than an unques-

tioning credulity. Both are alike detrimental to the force of investigation. Notwithstanding that for more than two thousand years the annals of different nations had recorded falls of meteoric stones, many of which had been attested beyond all doubt by the evidence of irreproachable eye-witnesses; notwithstanding the important part enacted by the bætyli in the meteor-worship of the ancients; notwithstanding the fact of the companions of Cortez having seen an aerolite at Cholula which had fallen on the neighboring pyramid; notwithstanding that califs and Mongolian chiefs had caused swords to be forged from recently fallen meteoric stones; nay, notwithstanding that several persons had been struck dead by stones falling from heaven, as, for instance, a monk at Crema on the 4th of September, 1511, another monk at Milan in 1650, and two Swedish sailors on board ship in 1674—yet this great cosmical phenomenon remained almost wholly unheeded, and its intimate connection with other planetary systems unknown, until attention was drawn to the subject by Chladni.—HUMBOLDT *Cosmos*, vol. i, p. 135. (H., 1897.)

1622. INDEPENDENCE WEAKENED BY SURVEILLANCE — *"Mother's Apron-strings"—Lack of Moral Perspective.*—It is an old and just observation that youths who have been "brought up at their mothers' apron-strings" are the most likely to "go wrong" when first thrown upon their own guidance; and that when such once begin to go astray they soonest run into wild excesses. The rationale of this seems to be that the tendency of such an education is usually to repress, instead of fostering, habits of independence and self-regulation; and too frequently to weaken, instead of strengthening, the force of moral obligation, by attaching to small things the same importance as to great. If a lad is constantly watched and never trusted, he is almost sure to abuse his liberty when he first acquires it. And if he is taken to task as severely for spilling ink on a table-cloth or for tearing his clothes, as for telling a lie or appropriating what does not belong to him, it is not to be wondered at that he should come to regard the graver offenses in the same light as those which he feels to be venial.—CARPENTER *Mental Physiology*, bk. i, ch. 9, p. 427. (A., 1900.)

1623. INDESTRUCTIBILITY OF THE ATOM—*An Unproved Assumption.*—The supposed indestructibility of the atom amounts merely to this, that with our limited range of experimental methods we have not been able to cause any appreciable portion of matter to disappear, as such, permanently, but can always recover it unchanged in mass and chemical properties. To assert that matter cannot, under any circumstances, be made to disappear as matter, seems to me to be the most unjustifiable dogma imaginable.—STOKES *The Atomic Theory from the Chemical Standpoint*, in *Science*, N. S., vol. xi, No. 277, April 20, 1900.

1624. INDESTRUCTIBILITY OF THREE GREAT POWERS—*Matter, Energy, Intelligence Imperishable.*—All modern chemistry rests on the great truth that *matter is indestructible, and is measured by weight*. . . . Another great central truth, more recently discovered, is not less far-reaching or important, namely, *energy is indestructible, and is measured by work*. Add to these two [truths] a third, namely, *intelligence is indestructible, and is measured by adaptation*, and you have, as it seems to me, the three great manifestations of Nature: *Matter, energy, and intelligence.* These great truths explain and supplement each other. Give to each its due weight in your philosophy, and you will avoid the extremes of idealism on the one side, and of materialism on the other.—COOKE *New Chemistry*, lect. 10, p. 235. (A., 1899.)

1625. INDIFFERENCE TO CATASTROPHE—*Lack of Record Is Not Disproof of Event.*—We must not conclude without alluding to a moral phenomenon connected with this tremendous catastrophe [the volcanic eruption in Sumbawa in 1815], which we regard as highly deserving the attention of geologists. It is stated by Sir A. Burnes that "these wonderful events passed unheeded by the inhabitants of Cutch"; for the region convulsed, tho once fertile, had for a long period been reduced to sterility by want of irrigation, so that the natives were indifferent as to its fate. Now it is to this profound apathy which all but highly civilized nations feel, in regard to physical events not having an immediate influence on their worldly fortunes, that we must ascribe the extraordinary dearth of historical information concerning changes of the earth's surface, which modern observations show to be by no means of rare occurrence in the ordinary course of Nature.

Since the above account was written, a description has been published of more recent geographical changes in the district of Cutch, near the mouth of the Koree, or eastern branch of the Indus, which happened in June, 1845. A large area seems to have subsided, and the Sindree Lake has become a salt marsh.—LYELL *Principles of Geology*, bk. ii, ch. 27, p. 464. (A., 1854.)

1626. INDIGO MANUFACTURED BY CHEMICAL PROCESS—*Indigo Farms Abandoned.*—To such an extent has this [manufacture of substances like the organic] been the case that in several instances the old methods of producing certain chemical compounds through the medium of cultivated plants has been entirely abandoned. Perhaps the most striking illustration of this is in the case of the indigo-plant. The cultivation of this plant and the manufacture of indigo therefrom were once profitable in-

dustries, but the manufacture of synthetic indigo and its substitutes in the chemical laboratory has so cheapened the price of this product as to render unprofitable the old processes. The indigo farms are therefore abandoned, and nearly the whole of the indigo of commerce is now manufactured by the chemist.—WILEY *Relations of Chemistry to Industrial Progress (Address at Purdue University, Lafayette, Ind.*, 1896, p. 28).

1627. INDIVIDUALISM CONTRARY TO NATURE'S PLAN—*Care Bestowed in Preparing Pollen—Precautions against Self-fertilization of Flowers.*—If we consider how precious a substance pollen is, and what care has been bestowed on its elaboration and on the accessory parts in the *Orchideæ*—considering how large an amount is necessary for the impregnation of the almost innumerable seeds produced by these plants—considering that the anther stands close behind or above the stigma, self-fertilization would have been an incomparably safer and easier process than the transportal of pollen from flower to flower. Unless we bear in mind the good effects which have been proved to follow in most cases from cross-fertilization, it is an astonishing fact that the flowers of the *Orchideæ* should not have been regularly self-fertilized. It apparently demonstrates that there must be something injurious in this latter process, of which fact I have elsewhere given direct proof. It is hardly an exaggeration to say that Nature tells us, in the most emphatic manner, that she abhors perpetual self-fertilization.—DARWIN *Fertilization of Orchids*, ch. 9, p. 293. (A., 1898.)

1628. INDIVIDUALISM GIVES PLACE TO ALTRUISM—Now the moment a man's voluntary actions are determined by conscious or unconscious reference to a standard outside of himself and his selfish motives, he has entered the world of ethics, he has begun to live in a moral atmosphere. Egoism has ceased to be all in all, and altruism—it is an ugly-sounding word, but seems to be the only one available—altruism has begun to assert its claim to sovereignty.—FISKE *Through Nature to God*, pt. ii, ch. 9, p. 104. (H. M. & Co., 1900.)

1629. INDIVIDUALITY A LAW OF NATURE—*No Organism Exactly Like Parent.*—Equally conspicuous with the truth that every organism bears a general likeness to its parents, is the truth that no organism is exactly like either parent. Tho similar to both in generic and specific traits, and usually, too, in those traits which distinguish the variety, it diverges in numerous traits of minor importance. No two plants are indistinguishable; and no two animals are without differences. Variation is coextensive with heredity.—SPENCER *Biology*, pt. ii, ch. 9, p. 320. (A., 1900.)

1630. INDIVIDUALITY INDESTRUCTIBLE—*No Complete Transference of Thought.*—The only states of consciousness that we naturally deal with are found in personal consciousnesses, minds, selves, concrete particular I's and you's. Each of these minds keeps its own thoughts to itself. There is no giving or bartering between them. No thought even comes into direct sight of a thought in another personal consciousness than its own. Absolute insulation, irreducible pluralism, is the law. It seems as if the elementary psychic fact were not *thought* or *this thought* or *that thought*, but *my thought*, every thought being *owned*. Neither contemporaneity, nor proximity in space, nor similarity of quality and content are able to fuse thoughts together which are sundered by this barrier of belonging to different personal minds. The breaches between such thoughts are the most absolute breaches in Nature.—JAMES *Psychology*, vol. i, ch. 9, p. 226. (H. H. & Co., 1899.)

1631. INDIVIDUALITY IN SCIENCE—*Variations and Discrepancies between Competent Observers—The "Personal Equation" in Observations.*—It was in 1823 that Bessel drew attention to discrepancies in the times of transits given by different astronomers. The quantities involved were far from insignificant. He was himself nearly a second in advance of all his contemporaries, Argelander lagging behind him as much as a second and a quarter. Each individual, in fact, was found to have a certain definite rate of perception, which, under the name of "personal equation," now forms so important an element in the correction of observations that a special instrument for accurately determining its amount in each case is in actual use at Greenwich.—CLERKE *History of Astronomy*, pt. i, ch. 6, p. 152. (Bl., 1893.)

1632. INDIVIDUALITY OF A REGION—*Each Has a Character of Its Own.*—As in some individual organic beings we recognize a definite physiognomy, and as descriptive botany and zoology are, strictly speaking, analyses of animal and vegetable forms, so also there is a certain natural physiognomy peculiar to every region of the earth. That which the painter designates by the expressions "Swiss scenery" or "Italian sky" is based on a vague feeling of the local natural character. The azure of the sky, the effects of light and shade, the haze floating on the distant horizon, the forms of animals, the succulence of plants, the bright glossy surface of the leaves, the outlines of mountains, all combine to produce the elements on which depends the impression of any one region.—HUMBOLDT *Views of Nature*, p. 217. (Bell, 1896.)

1633. INDIVIDUALITY OF MEMORY—*Seems Intuitive as Consciousness Itself.*—To challenge the veracity of a person's memory is one of the boldest things one can do in the way of attacking deep-seated conviction. Memory is the peculiar domain of the individual. In going back in recollection to the scenes of other years he is draw-

ing on the secret storehouse of his own consciousness, with which a stranger must not intermeddle. To cast doubt on a person's memory is commonly resented as an impertinence, hardly less rude than to question his reading of his own present mental state. Even if the challenger professedly bases his challenge on the testimony of his own memory, the challenged party is hardly likely to allow the right of comparing testimonies. He can in most cases boldly assert that those who differ from him are lacking in his power of recollection. The past, in becoming the past, has, for most people, ceased to be a common object of reference; it has become a part of the individual's own inner self, and cannot be easily dislodged or shaken.—SULLY *Illusions*, ch. 10, p. 232. (A., 1897.)

1634. INDIVIDUALITY, STRONG, IN CAT TRIBE—*Cats Never Hunt in Packs.*—Cats never hunt in packs as dogs and wolves do, and rarely pursue their prey in open ground, but spring upon it from some hiding-place. They are mostly nocturnal, and the greater number, especially of the smaller kinds, habitually live in trees.—MIVART *Types of Animal Life*, ch. 8, p. 226. (L. B. & Co., 1893.)

1635. INDIVIDUALITY, VARYING ASPECTS OF—*Men Discriminate between Their Own Different Selves—One's "Fame" and "Honor."*—A man's fame, good or bad, and his honor or dishonor are names for one of his social selves. The particular social self of a man called his honor is usually the result of one of those splittings of which we have spoken. It is his image in the eyes of his own "set" which exalts or condemns him as he conforms or not to certain requirements that may not be made of one in another walk of life. Thus a layman may abandon a city infected with cholera; but a priest or a doctor would think such an act incompatible with his honor. A soldier's honor requires him to fight or to die under circumstances where another man can apologize or run away with no stain upon his social self. A judge, a statesman, are in like manner debarred by the honor of their cloth from entering into pecuniary relations perfectly honorable to persons in private life. Nothing is commoner than to hear people discriminate between their different selves of this sort: "As a man I pity you, but as an official I must show you no mercy; as a politician I regard him as an ally, but as a moralist I loathe him," etc., etc.—JAMES *Psychology*, vol. i, ch. 10, p. 294. (H. H. & Co., 1899.)

1636. INDUCTION AND DEDUCTION MUST COMBINE—*No Single Method Leads to Truth.*—We must welcome as one of the most fortunate steps in the direction of a solution of the great cosmic problems the fact that of recent years there is a growing tendency to recognize the two paths which alone lead thereto—experience and thought, or speculation—to be of equal value and mutually complementary. Philosophers have come to see that pure speculation—such, for instance, as Plato and Hegel employed for the construction of their idealist systems—does not lead to knowledge of reality. On the other hand, scientists have been convinced that mere experience—such as Bacon and Mill, for example, made the basis of their realist systems—is sufficient of itself for a complete philosophy. For these two great paths of knowledge, sense-experience and rational thought, are two distinct cerebral functions; the one is elaborated by the sense-organs and the inner sense-centers, the other by the thought-centers, the great "centers of association in the cortex of the brain," which lie between the sense-centers. True knowledge is only acquired by combining the activity of the two.—HAECKEL *Riddle of the Universe*, ch. 1, p. 18. (H., 1900.)

1637. INDUCTION GIVES A LAW—*Deduction Supposes a Case—Experiment Furnishes the Test.*—To acquire [scientific] foreknowledge of what is coming, but of what has not been settled by observations, no other method is possible than that of endeavoring to arrive at the laws of facts by observations; and we can only learn them by induction, by the careful selection, collation, and observation of those cases which fall under the law. When we fancy that we have arrived at a law the business of deduction commences. It is then our duty to develop the consequences of our law as completely as may be, but in the first place only to apply to them the test of experience, so far as they can be tested, and then to decide by this test whether the law holds, and to what extent. This is a test which really never ceases.—HELMHOLTZ *Popular Lectures*, ser. ii, lect. 5, p. 226. (L. G. & Co., 1898.)

1638. INDUCTION RECOGNIZED BY ARISTOTLE—*Rules Given Only for Deduction.*—Altho the duality of the complex operation whereof induction is the first and deduction the second half, as well as the especial necessity for the inductive part, was recognized by Aristotle both in actual declarations and by his unwearied industry in collecting facts; altho, moreover, he perceived that all science or theory must rest upon this foundation as a whole, nevertheless he devotes himself only to the analysis and to the formulating of the rules of the deductive part. Thus it was, as Grote points out, that science afterwards became disjoined from experience and was presented as consisting in deduction alone, while everything not deduction became degraded into unscientific experience.—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 2, p. 39. (J. W., 1898.)

1639. INDULGENCE, EXCUSES FOR—*Mental Ingenuity in Finding Reasons for Wrong-doing—Fault Must Be Branded with the Name—"Being a Drunkard."*—Where,

however, the right conception is an anti-impulsive one, the whole intellectual ingenuity of the man usually goes to work to crowd it out of sight, and to find names for the emergency, by the help of which the dispositions of the moment may sound sanctified, and sloth or passion may reign unchecked. How many excuses does the drunkard find when each new temptation comes! It is a new brand of liquor which the interests of intellectual culture in such matters oblige him to test; moreover it is poured out and it is sin to waste it; or others are drinking and it would be churlishness to refuse; or it is but to enable him to sleep, or just to get through this job of work: or it isn't drinking, it is because he feels so cold; or it is Christmas day; or it is a means of stimulating him to make a more powerful resolution in favor of abstinence than any he has hitherto made; or it is just this once, and once doesn't count, etc., etc., *ad libitum*—it is, in fact, anything you like except *being a drunkard*. *That* is the conception that will not stay before the poor soul's attention. But if he once gets able to pick out that way of conceiving from all the other possible ways of conceiving the various opportunities which occur, if through thick and thin he holds to it that this is being a drunkard and is nothing else, he is not likely to remain one long. The effort by which he succeeds in keeping the right *name* unwaveringly present to his mind proves to be his saving moral act.—JAMES *Psychology*, vol. ii, ch. 26, p. 565. (H. H. & Co., 1899.)

1640. INDUSTRY AND PREVISION AMONG ANIMALS—*Storehouses and Gardens of Ants.*—The species of *Messor* (Europe), *Pogonomyrmex* (America), and *Holcomyrmex* (India) construct very large chambers, or granaries, underground, at a considerable depth, often at the depth of a yard, in which they store the seeds they have collected. In the same way the species of the American genus *Atta* excavate extremely deep and extensive passages, and make immense chambers, in which they store the leaves they have cut from the trees for the purpose of laying out upon them the fungus-gardens from which they supply thousands with food. This discovery, first made by Belt, and subsequently declared by MacCook to be incorrect, has recently been confirmed by Dr. Möller, of Blumenau, in its full extent as the result of superb experiments.—*Forel, Article on Ants' Nests*, p. 483 *(Report of Smithsonian Institute, 1894).*

1641. INDUSTRY DEPENDENT ON SCIENTIFIC STUDY—As in nobler spheres of thought and sentiment, in philosophy, poetry, and the fine arts, the object at which we aim ought to be an inward one—an ennoblement of the intellect—so ought we likewise, in our pursuit of science, to strive after a knowledge of the laws and the principles of unity that pervade the vital forces of the universe; and it is by such a course that physical studies may be made subservient to the progress of industry, which is a conquest of mind over matter. By a happy connection of causes and effects we often see the useful linked to the beautiful and the exalted. The improvement of agriculture in the hands of freemen, and on properties of a moderate extent—the flourishing state of the mechanical arts freed from the trammels of municipal restrictions—the increased impetus imparted to commerce by the multiplied means of contact of nations with each other are all brilliant results of the intellectual progress of mankind and of the amelioration of political institutions in which this progress is reflected. The picture presented by modern history ought to convince those who are tardy in awakening to the truth of the lesson it teaches.—HUMBOLDT *Cosmos*, vol. i, int., p. 54. (H., 1897.)

1642. INDUSTRY OF ANTS—*Systematic and Persevering Labor of Red Ants in India.*—Meer Hassan Ali, in his "History of the Mussulmans," expressly mentions that "More industrious little creatures cannot exist than the small red ants which are so abundant in India. I have watched them at their labors for hours without tiring. They are so small that from eight to twelve in number labor with great difficulty to convey a grain of wheat or barley, yet these are not more than half the size of a grain of English wheat. I have known them to carry one of these grains to their nest, at a distance from 600 to 1,000 yards. They travel in two distinct lines over rough or smooth ground, as it may happen, even up and down steps, at one regular pace. The returning unladen ants invariably salute the burthened ones who are making their way to the general storehouse; but it is done so promptly that the line is neither broken nor their progress impeded by the salutation."—AVEBURY *Ants, Bees and Wasps*, ch. 3, p. 60. (A., 1900.)

1643. INDUSTRY OF PRIMITIVE MAN—*Toil under Disadvantages.*—After having chosen a favorable situation the first step in the construction of the lake-habitations was to obtain the necessary timber. To cut down a tree with a stone hatchet must have been no slight undertaking. It is, indeed, most probable that use was made of fire in the same manner as is done by existing savages in felling trees and making canoes. Burning the wood and then scraping away the charred portion renders the task far more easy, and the men of the Stone period appear to have avoided the use of large trees, except in making their canoes. Their piles were embedded in the mud from one to five feet, and must also have projected from four to six feet above the water level, which cannot have been very different from what it is at present. They must, therefore, have had a length of from fifteen to thirty feet, and they were from three to nine inches in diameter. The point-

ed extremity which entered into the mud still bears the marks of the fire and the rude cuts made by the stone hatchets. The piles belonging to the Bronze period, being prepared with metal axes, were much more regularly pointed, and the differences between the two have been ingeniously compared to those shown by lead pencils well and badly cut.—AVEBURY *Prehistoric Times*, ch. 6, p. 176. (A., 1900.)

1644. INDUSTRY, SEPARATE VS. GREGARIOUS — *Ancient Implements Long Perpetuated—The Spindle of Egypt in the Highlands of Scotland.*—In 1760 the spinning-wheel and the common loom, as used by the people of Yorkshire, were little in advance of the implements for the same purpose which had been in use beyond the reach of history. The spindle which is depicted on the monuments of Egypt was until a few years ago familiar in the Highlands. The essential feature of this ancient industry, so far as its effects upon social conditions are concerned, was that it was separate and not gregarious. It did not interfere with, but rather was congenial to, family life for thousands of years.

"Maids at the wheel, the weaver at his loom,
Sat blithe and happy."

—ARGYLL *Reign of Law*, ch. 7, p. 206. (Burt.)

1645. INDUSTRY THE CORRECTIVE OF PHILANTHROPY—*Evolution Humanized.*—Men very naturally and very honestly disagree in respect to the activity of those causes which have helped the human race forward. Most of us accept the theory of evolution to account for the diversity and development of life, but when reason, education, and religion appear, they serve to counteract the forces which have produced evolution, and, in fact, to undo much of the work which the uninterrupted operation of natural law has performed. The tendency of civilization is therefore almost directly in opposition to those forces which have made humanity possible. As an illustration of this, attention may be called to the grand system of organized philanthropy which is found in every civilized community. The care which we bestow in public and in private on the old, the imbecile and the sick secures precisely what the great forces of evolution would eliminate and destroy. Were it not, then, for other forces to counteract the deteriorating effects of philanthropy, the human race, through its own excellence of heart, would rapidly regress. Fortunately, therefore, in the progress of human industry we find a factor which tends to correct or neutralize the enervating effects of philanthropy. The necessity of effort and the pleasure of labor drive men into pursuits which develop their faculties, increase their power, and eliminate, to a certain degree, the deteriorating effects of care, of helpfulness, of sympathy and affection. In this respect the progress of industry must be regarded as the great helper of humanity. Just in proportion as the industries of a nation broaden and develop, just in that proportion does the character of its citizens gain strength and their brains and muscles skill and power.—WILEY *Relations of Chemistry to Industrial Progress (Address at Purdue University, Lafayette, Ind., 1896)*, p. 13.

1646. INEQUALITY A LAW OF HUMAN NATURE—There is, for example, a law—an observed order of facts—in respect to man, which the working classes too often forget, but which can neither be violated nor neglected with impunity. That law is the law of inequality—the various degrees in which the gifts both of body and of mind are shared among men. This is one of the most fundamental facts of human nature. Nor is it difficult to see how it should be also one of the most beneficent. But it is a fact against which the spirit of combination is very apt to assume an attitude of permanent insurrection.—ARGYLL *Reign of Law*, ch. 7, p. 224. (Burt.)

1647. INFALLIBILITY, ASSUMED, OF SCIENTISTS—Many an anthropologist has described a skull of peculiar form as the only one of its kind, perhaps discovering in it greater or minor animal similarities, when typically it might have been mistaken for the one upon his own shoulders.—RANKE *Somatische anthropologische Beobachtungen (an address).* (Translated for *Scientific Side-Lights.)*

1648. INFANCY A PERIOD OF PLASTICITY—*Calls Out Parents' Unselfishness.*—The first appearance of infancy in the animal world heralded the new era which was to be crowned by the development of man. With the beginnings of infancy there came the first dawning of a conscious life similar in nature to the conscious life of human beings, and there came, moreover, on the part of parents, the beginning of feelings and actions not purely self-regarding. But, still more, the period of infancy was a period of plasticity. The career of each individual being no longer wholly predetermined by the careers of its ancestors, it began to become teachable. Individuality of character also became possible at the same time, and for the same reason.—FISKE *Destiny of Man*, ch. 6, p. 51. (H. M. & Co., 1900.)

1649. INFANCY PROLONGED—*Noticeable Fact among Apes.*—The young orangs seem to remain unusually long under their mother's protection, probably in consequence of their slow growth. While climbing the mother always carries her young against her bosom, the young holding on by his mother's hair.—HUXLEY *Man's Place in Nature*, p. 206. (Hum.)

1650. ——— ——— *The Chief Fact in Man's Development.*—In the genesis of humanity the central fact has been the in-

creased duration of infancy. Now, can we assign for that increased duration an adequate cause? I think we can. The increase of intelligence is itself such a cause. A glance at the animal kingdom shows us no such thing as infancy among the lower orders. It is with warm-blooded birds and mammals that the phenomena of infancy and the correlative parental care really begin.—FISKE *Through Nature to God*, pt. ii, ch. 6, p. 87. (H. M. & Co., 1900.)

1651. INFECTION CAUSED BY EARTHWORMS—Pasteur held that earthworms are responsible for conveying the spores and anthrax from buried carcasses to the surface, and thus bringing about reinfection.—NEWMAN *Bacteria*, ch. 5, p. 17. (G. P. P., 1899.)

1652. INFECTION WIDELY DISTRIBUTED—*Mistaken Attempt at Cleanliness Caused Pollution.*—Within the last twelve months much attention has been drawn to a milk-source of typhoid infection by the epidemic of typhoid at Bristol. Dr. D. S. Davies has pointed out that a brook received the sewage of thirty-seven houses, the overflow of a cesspool serving twenty-two more, the washings from fields over which the drainage of several others was distributed, and the direct sewage from at least one other, and then flowed directly through a certain farm. The water of this stream supplied the farm pump, and the water itself, it is scarcely necessary to add, was highly charged with putrescent organic matter and micro-organisms. This water was used for washing the milk-cans from this particular farm, otherwise the dairy arrangements were efficient. Part of the milk was distributed to fifty-seven houses in Clifton; in forty-one of them cases of typhoid occurred. Another part of the milk was sold over the counter; twenty households so obtaining it were attacked with typhoid fever, and a number of further infections and complications arose. This evidence would appear to support the fact that milk may act in the same way, tho not in such a high degree, as water in the conveyance of typhoid fever.—NEWMAN *Bacteria*, ch. 6, p. 199. (G. P. P., 1899.)

1653. INFINITUDE, RICHTER'S VISION OF—*"End There Is None!"*—Truly, the German poet Richter has spoken well in those wonderful words which our own prose poet De Quincey has so nobly translated; his splendid vision aptly expresses the feebleness of man's conceptions in the presence of the infinite wonders of creation:

"God called up from dreams a man into the vestibule of heaven, saying, 'Come thou hither, and see the glory of my house.' And to the angels which stood around his throne he said: 'Take him, strip from him his robes of flesh; cleanse his vision, and put a new breath into his nostrils, only touch not with any change his human heart, the heart that weeps and trembles.' It was done; and with a mighty angel for his guide the man stood ready for his infinite voyage; and from the terraces of heaven, without sound or farewell, at once they wheeled away into endless space. Sometimes with the solemn flight of angel wings they passed through Zaharas of darkness, through wildernesses of death, that divided the worlds of life; sometimes they swept over frontiers that were quickening under prophetic motions from God. Then from a distance which is counted only in heaven, light dawned for a time through a shapeless film; by unutterable pace the light swept to them, they by unutterable pace to the light. In a moment the rushing of planets was upon them; in a moment the blazing of suns was around them.

"Then came eternities of twilight, that revealed, but were not revealed. On the right hand and on the left towered mighty constellations, that by self-repetitions and answers from afar, that by counter-positions, built up triumphal gates, whose architraves, whose archways, horizontal, upright, rested, rose, at altitude, by spans that seemed ghostly from infinitude. Without measure were the architraves, past number were the archways, beyond memory the gates. Within were stairs that scaled the eternities around; above was below and below was above, to the man stripped of gravitating body: depth was swallowed up in height insurmountable, height was swallowed up in depth unfathomable. Suddenly, as thus they rode from infinite to infinite, suddenly, as thus they tilted over abysmal worlds, a mighty cry arose that systems more mysterious, that worlds more billowy, other heights and other depths, were coming, were nearing, were at hand.

"Then the man sighed and stopped, shuddered, and wept. His overladen heart uttered itself in tears, and he said, 'Angel, I will go no farther: for the spirit of man acheth with this infinity. Insufferable is the glory of God. Let me lie down in the grave, and hide me from the persecution of the Infinite, for end I see there is none.' And from all the listening stars that shone around issued a choral voice, 'The man speaketh truly: end there is none that ever yet we heard of!' 'End is there none?' the angel solemnly demanded: 'is there indeed no end? And is this the sorrow that fills you?' But no voice answered, that he might answer himself. Then the angel threw up his glorious hands to the heaven of heavens, saying: 'End is there none to the universe of God. Lo! also, there is no beginning.'"—PROCTOR *Expanse of Heaven*, p. 304. (L. G. & Co., 1897.)

1654. INFINITY A NECESSITY OF HUMAN THOUGHT—*Space and Time—Matter and Force.*—When now we consider the place in the whole system of our knowledge which is occupied by these great fundamental conceptions of time and space, and of matter and of force, and when we con-

sider that we cannot even think of any one of these realities as capable of coming to an end, we may well be assured that, whatever may be the limits of the human mind, they certainly do not prevent us from apprehending infinity. On the contrary, it would rather appear that this apprehension is the invariable and necessary result of every investigation of Nature.—ARGYLL *Unity of Nature*, ch. 4, p. 84. (Burt.)

1655. INFINITY NOT AN OBJECT OF WORSHIP—*Infinite Space, Time, Number Not Religious—Misfortune of Ambiguity.*—The phrase, now often used to express the objects of religious thought and feeling, "the Infinite," is . . . ambiguous, not merely as "the Supernatural" is ambiguous, by reason of its involving a separate and adventitious meaning besides the meaning which is prominent and essential; but it is ambiguous by reason of not necessarily containing at all the one meaning which is essential to religion. "The Infinite" is a pure and bare abstraction, which may or may not include the one only object of religious consciousness and thought. An Infinite Being, if that be the meaning of "the Infinite," is, indeed, the highest and most perfect object of religion. But an infinite space is no object of religious feeling. An infinite number of material units is no object of religious thought. Infinite time is no object of religious thought. On the other hand, infinite power not only may be, but must be, an object of religious contemplation in proportion as it is connected with the idea of power in a living will. Infinite goodness must be the object of religious thought and emotion, because in its very nature this conception involves that of a personal being. But if all this is what is intended by "the Infinite," then it would be best to say so plainly. The only use of the phrase, as the one selected to indicate the object of religion, is that it may be understood in a sense that is kept out of sight.—ARGYLL *Unity of Nature*, ch. 11, p. 272. (Burt.)

1656. INFINITY OF SPACE, MATTER, AND ENERGY—*Science Leads Out to the Infinite.*—Infinity of space and of matter occupying space, of time and of the processes with which time is occupied, and infinity of energy as necessarily implied by the infinities of matter and of the operations affecting matter—these infinities science brings clearly before us. For science directs our thoughts to the finites to which these infinites correspond. It shows us that there can be no conceivable limits to space or time, and tho finiteness of matter or of operation may be conceivable, there is manifest incongruity in assuming an infinite disproportion between unoccupied and occupied space, or between void time and time occupied with the occurrence of events of what sort soever. So that the teachings of science bring us into the presence of the unquestionable infinities of time and of space, and the presumable infinities of matter and of operation—hence, therefore, into the presence of infinity of energy. But science teaches us nothing about these infinities, as such. They remain none the less inconceivable, however clearly we may be taught to recognize their reality.—PROCTOR *Our Place among Infinities*, p. 1. (L. G. & Co., 1897.)

1657. INFINITY REVEALED IN NATURE—The earnest and solemn thoughts awakened by a communion with Nature intuitively arise from a presentiment of the order and harmony pervading the whole universe, and from the contrast we draw between the narrow limits of our own existence and the image of infinity revealed on every side, whether we look upward to the starry vault of heaven, scan the far-stretching plain before us, or seek to trace the dim horizon across the vast expanse of ocean.—HUMBOLDT *Cosmos*, vol. i, int., p. 25. (H., 1897.)

1658. INFINITY SUGGESTED BY THE OCEAN—However much this richness [of the ocean] in animated forms, and this multitude of the most various and highly developed microscopic organisms may agreeably excite the fancy, the imagination is even more seriously, and, I might say, more solemnly moved by the impression of boundlessness and immeasurability which are presented to the mind by every sea-voyage. All who possess an ordinary degree of mental activity, and delight to create to themselves an inner world of thought, must be penetrated with the sublime image of the infinite when gazing around them on the vast and boundless sea, when involuntarily the glance is attracted to the distant horizon, where air and water blend together, and the stars continually rise and set before the eyes of the mariner. This contemplation of the eternal play of the elements is clouded, like every human joy, by a touch of sadness and of longing.—HUMBOLDT *Cosmos*, vol. i, p. 310. (H., 1897.)

1659. INFINITY, THE CONCEPTION OF—*A Necessity of Human Thought.*—"That the finite cannot comprehend the infinite" is a proposition constantly propounded as an undoubted and all-comprehensive truth. Such truth as does belong to it seems to come from the domain of physics, in which it represents the axiom that a part cannot be equal to the whole. From this, in the domain of mind, it comes to represent the truth, equally undeniable, that we cannot know all that infinity contains. But the meaning into which it is liable to pass when applied to mind is that man cannot conceive infinity. And never was any proposition so commonly accepted which, in this sense, is so absolutely devoid of all foundation. Not only is infinity conceivable by us, but it is inseparable from conceptions which

are of all others the most familiar. Both the great conceptions of space and time are, in their very nature, infinite. We cannot conceive of either of these as subject to limitation. We cannot conceive of a moment after which there shall be no more time, nor of a boundary beyond which there is no more space. This means that we cannot but think of space as infinite and of time as everlasting.—ARGYLL *Unity of Nature*, ch. 4, p. 79. (Burt.)

1660. INFIRMITY UNCONSCIOUS— *Color-blindness Only Discovered by Comparison.*—It is an interesting fact in reference to the dependence of at least one class of our knowledge on sensation, that many persons are born with defective vision and yet remain for years of their lives without being conscious of the deficiency. We know a gentleman who had probably been always near-sighted, but who did not discover the peculiarity of his vision until the age of twenty-five, when it was accidentally made known by looking at a distant object through a concave lens. Many persons whose eyes are sound and capable of exercising the most delicate functions, are permanently unable to distinguish certain colors. And the number of such persons is much more considerable than we would be led to imagine from the little attention this defect of vision has excited. It is often unknown to the individual himself, and indeed only becomes revealed by comparing his powers of discriminating different colors with those of other persons.—HENRY *Color-Blindness (Scientific Writings*, vol. i. p. 233). (Sm. Inst., 1886.)

1661. ——— ——— *Experience of a Child with Color-blindness.*—An account is given . . . of a shoemaker, in Cumberland, who could distinguish in different colors only a greater or less intensity of light, calling all bright tints white and all dull ones black. His peculiarity of vision was unknown to him until one day, while a boy, playing in the street, he found a stocking, and for the first time was struck with the fact that it was called by his companions red, whereas to his mind it was capable of no farther description than that designated by the word "stocking"; he was thus led to conclude that there was something else besides the form and position in the leaves and fruit of a cherry-tree, perceived by his playmates, but not seen by himself.—HENRY *Color-Blindness (Scientific Writings*, vol. i. p. 235). (Sm. Inst., 1886.)

1662. INFLUENCE EXERTED IN VAIN— *Air Unwarmed by Burning Solar Rays.*—On a sunny day you may see the summits of the high Alps glistening with the water of liquefaction. The air above and around the mountains may at the same time be many degrees below the freezing-point in temperature. . . . Solar beams powerful enough to fuse the snows and blister the human skin, nay, it might be added, powerful enough, when concentrated, to burn up the human body itself, may pass through the air, and still leave it at an icy temperature.—TYNDALL *Forms of Water*, pp. 100-102. (A., 1899.)

1663. INFLUENCE, FAR-REACHING, OF ONE GREAT MAN— *Roger Bacon the Scientific Light of the Middle Ages.*—In all that has directly operated on the extension of the natural sciences, and on their establishment on a mathematical basis, and by the calling forth of phenomena by the process of experiment, Roger Bacon, the cotemporary of Albertus of Bollstädt, may be regarded as the most important and influential man of the Middle Ages. These two men occupy almost the whole of the thirteenth century; but to Roger Bacon belongs the merit that the influence which he exercised on the form of the mode of treating the study of Nature has been more beneficial and lasting than the various discoveries which, with more or less justice, have been ascribed to him. Stimulating the mind to independence of thought, he severely condemned the blind faith attached to the authority of the schools, yet, far from neglecting the investigations of the ancient Greeks, he directed his attention simultaneously to philological researches, and the application of mathematics and of the *Scientia experimentalis*, to which last he devoted a special section of the "Opus Majus." Protected and favored by one pope (Clement IV.), and accused of magic and imprisoned by two others (Nicholas III. and IV.), he experienced the changes of fortune common to great minds in all ages.—HUMBOLDT *Cosmos*, vol. ii, pt. ii. p. 245. (H., 1897.)

1664. INFLUENCE FROM AFAR— *Attraction of the Sun for the Magnetic Needle.*—It had long been noticed that during the course of a single day the magnetic needle exhibits a minute change of direction, taking place in an oscillatory manner. And when the character of this vibration came to be carefully examined, it was found to correspond to a sort of effort on the needle's part to turn toward the sun. For example, when the sun is on the magnetic meridian, the needle has its mean position. This happens twice in the day, once when the sun is above the horizon, and once when he is below it. Again, when the sun is midway between these two positions—which also happens twice in the day—the needle has its mean position, because the northern and the southern ends make equal efforts, so to speak, to direct themselves toward the sun. Four times in the day, then, the needle has its mean position, or is directed toward the magnetic meridian. But when the sun is not in one of the four positions considered, that end of the needle which is nearest to him is slightly turned away from its mean position, toward him. The change of position is very minute, and only the exact methods of observation made use of in the present age would have sufficed to reveal it.

There it is, however, and this minute and seemingly unimportant peculiarity has been found to be full of meaning.—PROCTOR *Other Worlds than Ours*, ch. 2, p. 41. (Burt.)

1665. INFLUENCE, MYSTERIOUS, OF THE SUN ON THE MAGNETIC NEEDLE—*Correspondence of Oscillations of the Needle with Sun-spots.*—The amplitude of these diurnal oscillations [of the magnetic needle] varies every day, every month, every year. If we take the mean of the observations for a whole year, we ascertain that this oscillation may lengthen from single to double in a period of about 11 years, which period—a fact eminently worthy of attention—corresponds to that of the solar spots, *the maximum of the oscillations coinciding with the maximum of the spots, and the minimum with the minimum!* All the other elements of magnetism, inclination, and intensity show the same relation. Further, the magnetic needle manifests from time to time abnormal variations, perturbations caused by magnetic storms; *these perturbations also coincide with the great agitations observed in the sun!*—FLAMMARION *Popular Astronomy*, bk. iii, ch. 5, p. 288. (A.)

1666. INFLUENCE OF AN ENLIGHTENED MONARCH—*Ornithology Encouraged by Queen Isabella.*—Columbus brought home from his first voyage of discovery some natural products, as, for instance, fruits and the skins of animals. In a letter written from Segovia (August, 1494), Queen Isabella enjoins on the admiral to persevere in his collections; and she especially requires of him that he should bring with him specimens of "all the coast and forest birds peculiar to countries which have a different climate and different seasons."—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 274. (H., 1897.)

1667. INFLUENCE OF CULTIVATION—*Evolution of the Cabbage—Cause Still To Seek—Plants that Stubbornly Resist Improvement.*—There is no more remarkable example of the alteration produced by more abundant supply of food and more regulated temperature than that exhibited in the development of the wild *Brassica oleracea*, a rambling seashore plant, into the various kinds of cabbage, broccoli, and cauliflower. Why will not culture produce the like effect upon other plants? It is quite illogical to say that this transformation has been the effect of "physical causes," when the most essential factor in that entire "aggregate of antecedents," which (according to J. S. Mill) constitutes the "cause," is the "unknown quantity" which we designate as the "constitution" of the organism itself. As I have already pointed out, we do not get any nearer to the explanation of this constitution by tracing it backwards ancestrally; for supposing *Rosa*, *Rubus*, *Salix*, and *Brassica* to have derived their respective peculiarities by "natural selection" from among previous varieties, the question recurs, Whence those varietal modifications? No physical agencies can be assigned, at any stage whatever of the descent, as an adequate account of them; since, for those agencies to take effect there must have been a concurrent capacity for variation, either in the organism itself or in its germ, in virtue of which its varietal forms were engendered. The necessity for this factor is evinced by the negative results of its deficiency, shown in the "rareness" of many wild plants, and the unconquerable resistance made by others to all improvement by cultivation.—CARPENTER *Nature and Man*, lect. 15, p. 437. (A., 1889.)

1668. INFLUENCE OF GEOGRAPHIC CONDITIONS ON HISTORY—This triple constriction of the Mediterranean [into Ægean, Syrtic, and Tyrrhenian basins] has exercised a great influence on the earliest limitations and the subsequent extension of Phenician and Greek voyages of discovery. The latter were long limited to the Ægean and Syrtic seas. In the Homeric times the continent of Italy was still an "unknown land." The Phocæans opened the Tyrrhenian basin west of Sicily, and Tartessian mariners reached the Pillars of Hercules. It must not be forgotten that Carthage was founded at the boundary of the Tyrrhenian and Syrtic basins. The physical configuration of the coast line influenced the course of events, the direction of nautical undertakings, and the changes in the dominion of the sea; and the latter reacted again on the enlargement of the sphere of ideas.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 120. (H., 1897.)

1669. INFLUENCE OF HEAT AND COLD ON WATER—*Ice Lighter than Water.*—Like almost all other substances, water is expanded by heat and contracted by cold. . . . A small flask is filled with colored water and stopped with a cork. Through the cork passes a glass tube, water-tight, the liquid standing at a certain height in the tube. The flask and its tube resemble the bulb and stem of a thermometer. Applying the heat of a spirit-lamp, the water rises in the tube and finally trickles over the top. Expansion by heat is thus illustrated. Removing the lamp and piling a freezing mixture round the flask the liquid column falls, thus showing the contraction of the water by the cold. But let the freezing mixture continue to act, the falling of the column continues to a certain point; it then ceases. The top of the column remains stationary for some seconds, and afterwards begins to rise. The contraction has ceased, and expansion by cold sets in. Let the expansion continue till the liquid trickles a second time over the top of the tube. The freezing mixture has here produced to all appearance the same effect as the flame. In the case of water, contraction by cold

ceases and expansion by cold sets in at the definite temperature of 39° F. Crystallization has virtually here commenced, the molecules preparing themselves for the subsequent act of solidification which occurs at 32°, and in which the expansion suddenly culminates. In virtue of this expansion, ice, as you know, is lighter than water in the proportion of 8 to 9.—TYNDALL *Lectures on Light*, lect. 3, p. 107. (A., 1898.)

1670. INFLUENCE OF NATURE ON POETRY—*Cicero's Descriptions True to Fact.*—In Cicero's smaller sketches of Nature we find, as has been remarked, all things described as they still exist in the actual landscape; we see the Liris shaded by lofty poplars; and as we descend from the steep mountain behind the old towers of Arpinum we see the grove of oaks on the margin of the Fibrenus, and the island now called Isola di Carnello, which is formed by the division of the stream, and whither Cicero retired in order, as he said, to "give himself up to meditation, reading, and writing." Arpinum, situated on the Volscian Hills, was the birthplace of the great statesman, and its noble scenery no doubt exercised an influence on his character in boyhood. Unconsciously to himself the external aspect of the surrounding scenery impresses itself upon the soul of man with an intensity corresponding to the greater or less degree of his natural susceptibility, and becomes closely interwoven with the deep original tendencies and the free natural disposition of his mental powers.—HUMBOLDT *Cosmos*, vol. ii, pt. i, p. 31. (H., 1897.)

1671. INFLUENCE TRANSMITTED—*Color-photography—Telephone and Phonograph.*—The principle [of color-photography] is the same for the light-waves as that of the telephone for sound-waves. The voice sets up vibrations in the transmitting diaphragm, which by means of an electric current are so exactly reproduced in the receiving diaphragm as to give out the same succession of sounds. An even more striking and perhaps closer analogy is that of the phonograph, where the vibrations of the diaphragm are permanently registered on a wax cylinder, which at any future time can be made to set up the same vibrations of the air, and thus reproduce the same succession of sounds, whether words or musical notes.—WALLACE *The Wonderful Century*, ch. 5, p. 36. (D. M. & Co., 1899.)

1672. INGENUITY OF A SPIDER—*Web Stayed by Suspended Weight.*—J. G. Wood ("Glimpses into Petland") [relates the following incident]: "One of my friends," says Wood, "was accustomed to grant shelter to a number of garden spiders under a large veranda, and to watch their habits. One day a sharp storm broke out and the wind raged so furiously through the garden that the spiders suffered damage from it, altho sheltered by the veranda. The main-yards of one of these webs, as the sailors would call them, were broken, so that the web was blown hither and thither like a slack sail in a storm. The spider made no fresh threads, but tried to help itself in another way. It let itself down to the ground by a thread and crawled to a place where lay some splintered pieces of a wooden fence thrown down by the storm. It fastened a thread to one of the bits of wood, turned back with it, and hung it with a strong thread to the lower part of its nest, about five feet from the ground. The performance was a wonderful one, for the weight of the wood sufficed to keep the nest tolerably firm, while it was yet light enough to yield to the wind and so prevent further injury. The piece of wood was about two and a half inches long and as thick as a goose-quill. On the following day a careless servant knocked her head against the wood and it fell down. But in the course of a few hours the spider had found it and brought it back to its place. When the storm ceased the spider mended her web, broke the supporting thread in two, and let the wood fall to the ground!"—ROMANES *Animal Intelligence*, ch. 6, p. 221. (A., 1899.)

1673. INGENUITY OF PRIMITIVE MAN—*Picks Made of Deer's Horns.*—The implements used in making these excavations were deer's horns, the brow tine being used as a pick, and the others removed. Thus treated, a deer's horn closely resembles in form a modern pick, but of course it is subject to rapid wear by use, which accounts for the large numbers of worn-out implements found by Mr. Greenwell among the rubbish.—AVEBURY *Prehistoric Times*, ch. 4, p. 79. (A., 1900.)

1674. INGRATITUDE—*The Sun an Unrecognized Benefactor—Unappreciated Beneficence.*—The sun is an emblem of the Almighty in the manner in which he bestows benefits upon us and is forgotten. Day after day we enjoy the sun's light and heat; clouds may conceal him from our view, much as troubles may cause us to forget God: and the heat he pours out may seem sometimes insufficient or excessive, even as in our ignorance we are dissatisfied with the blessings bestowed by the Almighty.—PROCTOR *Expanse of Heaven*, p. 12. (L. G. & Co., 1897.)

1675. INHERITANCE OF MENTAL DISEASE—*Insanity in Royal Families.*—It is in reigning families that mental disorders are hereditary in an unusual degree. Thus Esquirol, distinguished for his knowledge of mental diseases, proved that the number of insane individuals in the reigning houses was, in proportion to the number among the ordinary population, as 60 to 1; that is, that disorders of the brain occur 60 times more frequently in the privileged families of the ruling houses than among ordinary people. This phenomenon can scarcely astonish us when we consider what injury these privileged castes inflict upon them-

selves by their unnatural, one-sided education, and by their artificial separation from the rest of mankind. By this means many dark sides of human nature are specially developed and, as it were, artificially bred, and according to the laws of transmission by inheritance are propagated through series of generations with ever-increasing force and dominance.—HAECKEL *History of Creation*, vol. i, ch. 8, p. 186. (K. P. & Co., 1899.)

1676. INHERITANCE THE RULE— *Non-inheritance the Anomaly.*—If strange and rare deviations of structure are really inherited, less strange and commoner deviations may be freely admitted to be inheritable. Perhaps the correct way of viewing the whole subject would be to look on the inheritance of every character whatever as the rule, and non-inheritance as the anomaly. [See also HEREDITY.]—DARWIN *Origin of Species*, ch. 1, p. 12. (Burt.)

1677. INHERITANCE THROUGH COUNTLESS GENERATIONS—*Bobolink of Utah Follows Ancestral Path Southward.*—Existing conditions [of bird-migration] are the result of changes which have been active for ages. No species, therefore, has acquired its present summer range at one step, but by gradually adding new territory to its breeding-ground. For example, certain of our Eastern birds are evidently derived through Mexico, and in returning to their winter quarters in Central America they travel through Texas and Mexico, and are unknown in Florida and the West Indies. Others have come to us through Florida, and in returning to their winter quarters do not pass through either Texas or Mexico. This is best illustrated by the bobolink, an Eastern bird which, breeding from New Jersey northward to Nova Scotia, has spread westward until it has reached Utah and northern Montana. But—and here is the interesting point—these birds of the Far West do not follow their neighbors and migrate southward through the Great Basin into Mexico, but, true to their inherited habit, retrace their steps and leave the United States by the roundabout way of Florida, crossing thence to Cuba, Jamaica, and Yucatan, and wintering south of the Amazon. The bobolinks of Utah did not learn this route in one generation; they inherited the experience of countless generations, slowly acquired as the species extended its range westward, and in returning across the continent they give us an excellent illustration of the stability of routes of migration.—CHAPMAN *Bird-Life*, ch. 4, p. 60. (A., 1900.)

1678. INHUMANITY AMID PERIL AND SUFFERING—*Robbers Plunder Victims of Earthquake.*—It is supposed that [in the great Calabrian earthquake, 1783] about a fourth part of the inhabitants of Polistina, and of some other towns, were buried alive, and might have been saved had there been no want of hands; but in so general a calamity, where each was occupied with his own misfortunes or those of his family, aid could rarely be obtained. Neither tears nor supplications nor promises of high rewards were listened to. Many acts of self-devotion, prompted by parental and conjugal tenderness, or by friendship or the gratitude of faithful servants, are recorded; but individual exertions were, for the most part, ineffectual. It frequently happened that persons in search of those most dear to them could hear their moans, could recognize their voices, were certain of the exact spot where they lay buried beneath their feet, yet could afford them no succor. The piled mass resisted all their strength and rendered their efforts of no avail.

At Terranuova four Augustin monks, who had taken refuge in a vaulted sacristy, the arch of which continued to support an immense pile of ruins, made their cries heard for the space of four days. One only of the brethren of the whole convent was saved, and "of what avail was his strength to remove the enormous weight of rubbish which had overwhelmed his companions"? He heard their voices die away gradually, and when afterwards their four corpses were disinterred they were found clasped in each other's arms. Affecting narratives are preserved of mothers saved after the fifth, sixth, and even seventh day of their interment, when their infants or children had perished with hunger.

It might have been imagined that the sight of sufferings such as these would have been sufficient to awaken sentiments of humanity and pity in the most savage breasts; but while some acts of heroism are related, nothing could exceed the general atrocity of conduct displayed by the Calabrian peasants; they abandoned the farms and flocked in great numbers into the towns—not to rescue their countrymen from a lingering death, but to plunder. They dashed through the streets, fearless of danger, amid tottering walls and clouds of dust, trampling beneath their feet the bodies of the wounded and half-buried, and often stripping them, while yet living, of their clothes.—LYELL *Principles of Geology*, bk. ii, ch. 28, p. 491. (A., 1854.)

1679. INITIATIVE, DESTRUCTION OF—*Cutting Off Cerebral Hemispheres of Frog—Animal Becomes Automatic Machine.*—When a frog's cerebral hemispheres alone are cut off by a section between them and the thalami, which preserves the latter, an unpractised observer would not at first suspect anything abnormal about the animal. Not only is he capable, on proper instigation, of all the acts already described [of ordinary life], but he guides himself by sight, so that if an obstacle be set up between him and the light, and he be forced to move forward, he either jumps over it or swerves to one side. . . . Thus far, as aforesaid, a person unfamiliar with frogs might not suspect a mutilation; but even such a person would

soon remark the almost entire absence of spontaneous motion—that is, motion unprovoked by any present incitation of sense. The continued movements of swimming performed by the creature in the water seem to be the fatal result of the contact of that fluid with its skin. They cease when a stick, for example, touches his hands. This is a sensible irritant towards which the feet are automatically drawn by reflex action, and on which the animal remains sitting. He manifests no hunger and will suffer a fly to crawl over his nose unsnapped at. Fear, too, seems to have deserted him. In a word, he is an extremely complex machine whose actions, so far as they go, tend to self-preservation; but still a machine, in this sense—that it seems to contain no incalculable element. By applying the right sensory stimulus to him we are almost as certain of getting a fixed response as an organist is of hearing a certain tone when he pulls out a certain stop.—JAMES *Psychology*, vol. i, ch. 2, p. 17. (H. H. & Co., 1899.)

1680. INJURY BY INDIRECTION—*Products of Bacteria More Harmful than the Organisms Themselves—Toxins.*—Yet there is something of far greater importance than the mere presence of bacteria in human or animal tissues; for the secondary action of disease-producing germs—and possibly it is present in all bacteria—is due to their poisonous products, or toxins, as they have been termed. These may be of the nature of ferments, and they become diffused throughout the body, whether the bacteria themselves occur locally or generally. They may bring about very slight and even imperceptible changes during the course of the disease, or they may kill the patient in a few hours. Latterly bacteriologists have come to understand that it is not so much the presence of organisms which is injurious to man and other animals, as it is their products which cause the mischief; and the amount of toxic product bears no known proportion to the degree of invasion by the bacteria. The various and widely differing modes of action in bacteria are therefore dependent upon these three elements: the tissues or medium, the bacteria, and the products of the bacteria; and in all organismal processes these three elements act and react upon each other.—NEWMAN *Bacteria*, ch. 1, p. 28. (G. P. P., 1899.)

1681. INSANITY, MORAL, MAY BE CONGENITAL—*Children of Better Classes Sometimes Hopelessly Depraved.*—From time to time we are consulted about perplexing cases of what might be called moral insanity, or, more properly, moral imbecility, in children of the better classes. Tho born in good circumstances of life and having every advantage of education, they cannot, by any care or training, be made to learn and behave like other children; they display no affection whatever for parents, brothers, or sisters, and no real appreciation of the difference between right and wrong—no love for the one, no remorse for the other; they are inherently vicious, and steal and lie with a skill that it is hard to believe could ever have been acquired—are, in fact, instinctive thieves and liars; everything that their vicious nature prompts them to desire is for them right, and they exhibit a remarkable cunning in gratifying their evil propensities; they are the hopeless pupils of any master who has anything to do with them, and are sure to be expelled from any school to which they may be sent. In the end all those who have to do with them are constrained to ascribe to defect what at first seemed simple badness. Now, what we commonly find in these cases, when we are able to push satisfactory inquiry into their hereditary antecedents, is that they come of families in which insanity or some allied neurosis prevails.—MAUDSLEY *Body and Mind*, lect. 4, p. 111. (A., 1898.)

1682. INSECT WITH BIRD-LIKE HABIT—*Wasp Feeding Its Young.*—Its [the *Monedula* wasp's] singular habits and intelligence give it a still better claim to notice. It is a big, showy, loud-buzzing insect, with pink head and legs, wings with brown reflections, and body encircled with alternate bands of black and pale gold, and has a preference for large composite flowers, on the honey of which it feeds. Its young is, however, an insect-eater; but the *Monedula* does not, like other burrowing or sand wasps, put away a store of insects or spiders, partially paralyzed, as a provision for the grub till it reaches the pupa state; it actually supplies the grub with fresh-caught insects as long as food is required, killing the prey it captures outright, and bringing it in to its young, so that its habits, in this particular, are more bird- than wasp-like.—HUDSON *Naturalist in La Plata*, ch. 12, p. 163. (C. & H., 1895.)

1683. INSECT-LIFE, RICHNESS OF, IN TROPICS—*Number and Splendor of Butterflies in Brazil—Luxuriance of Beauty in Wilderness.*—It will convey some idea of the diversity of butterflies when I mention that about 700 species of that tribe are found within an hour's walk of the town [Para], while the total number found in the British Islands does not exceed 66, and the whole of Europe supports only 321. Some of the most showy species, such as the swallow-tailed kinds, *Papilio polycaon*, *thoas*, *torquatus*, and others, are seen flying about the streets and gardens; sometimes they come through the open windows, attracted by flowers in the apartments. Those species of *Papilio* which are most characteristic of the country, so conspicuous in their velvety-black, green and rose-colored hues, which Linnæus, in pursuance of his elegant system of nomenclature—naming the different kinds after the heroes of Greek mythology—called Trojans, never leave the shades of the forest. The splendid metallic blue

morphos, some of which measure seven inches in expanse, are generally confined to the shady valleys of the forest. They sometimes come forth into the broad sunlight. When we first went to look at our new residence in Nazareth a *Morpho menelaus*, one of the most beautiful kinds, was seen flapping its huge wings like a bird along the veranda. This species, however, altho much admired, looks dull in color by the side of its congener, the *Morpho rhetenor*, whose wings, on the upper face, are of quite a dazzling luster.—BATES *Naturalist on the River Amazon*, ch. 3, p. 643. (Hum., 1880.)

1684. INSECTS, ACUTE SENSES OF —*Bees, Butterflies, and Wasps Guided by Sight or Scent.*—That bees and butterflies have this power [of distinguishing between colors] is manifest. They may be watched flying from flower to flower, disregarding all other parts of the plants. . . . Odors, like colors, draw insects to flowers. After observing how bees come swarming into a house where honey is largely exposed, or how wasps find their way into a shop containing much ripe fruit, it cannot be questioned that insects are to a considerable extent guided by scent. Being thus sensitive to the aromatic substances which flowers exhale, they may, when the flowers are in large masses, be attracted by them from distances at which the flowers themselves are invisible.—SPENCER *Biology*, pt. v, ch. 3, p. 268. (A., 1900.)

1685. INSECTS, CAPTURE OF, BY SUNDEW—*Tentacles of Leaf Close as if by Design upon Victim—Action Irresistible of Natural Mechanism.*—When an insect alights on the central disk [of the sundew leaf], it is instantly entangled by the viscid secretion, and the surrounding tentacles after a time begin to bend, and ultimately clasp it on all sides. Insects are generally killed, according to Dr. Nitschke, in about a quarter of an hour, owing to their tracheæ being closed by the secretion. If an insect adheres to only a few of the glands of the exterior tentacles, these soon become inflected and carry their prey to the tentacles next succeeding them inwards; these then bend inwards, and so onwards, until the insect is ultimately carried by a curious sort of rolling movement to the center of the leaf. Then, after an interval, the tentacles on all sides become inflected and bathe their prey with their secretion, in the same manner as if the insect had first alighted on the central disk. It is surprising how minute an insect suffices to cause this action: for instance, I have seen one of the smallest species of gnats (*culex*), which had just settled with its excessively delicate feet on the glands of the outermost tentacles, and these were already beginning to curve inwards, tho not a single gland had as yet touched the body of the insect. Had I not interfered, this minute gnat would assuredly have been carried to the center of the leaf and been securely clasped on all sides.—DARWIN *Insectivorous Plants*, ch. 1, p. 13. (A., 1900.)

1686. INSECTS FERTILIZING FLOWERS—*Horticulturist Aided by Science —The Smyrna Fig Culture Made Possible in the United States.*—That an article bearing this title ["Smyrna Fig Culture in the United States"] should be prepared by an entomologist may seem at first glance unusual, not to say curious; but as is well known to those informed on the subject, and as will be readily seen by the readers of this article, the problem of establishing the Smyrna fig industry in the United States has been very largely an entomological problem. . . . Since time immemorial it has been known that in Oriental regions it has been the custom of the natives to break off the fruits of the capifig, bring them to the edible-fig trees, and tie them to the limbs. From the caprifigs thus brought in there issues a minute insect, which, covered with pollen, crawls into the flower receptacles of the edible fig, fertilizes them, and thus produces a crop of seeds and brings about the subsequent ripening of the fruit. . . . In the caprifig there is said to exist in Mediterranean regions three crops of fruit—the spring crop, known as "profichi," the second as "mammoni," and the third as "mamme," the latter remaining upon the trees through the winter. The fig insects (the Oriental species being known as *Blastophaga grossorum*, Gravenhorst) overwinter in the mamme, oviposit in the profichi, develop a generation within it, each individual living in the swelling of a gall-flower (a modified and infertile female flower), and issue from it covered with pollen, enter the young flower-receptacles of the Smyrna fig, which are at that time of the proper size, and make an attempt to oviposit in the true female flowers, fertilizing them at the same time by means of the pollen adhering to their bodies.

[As the result of the researches and experiments of the Entomological Division of the Department of Agriculture, this insect (the *Blastophaga*) has now been naturalized in California, so that in the year 1899-1900 more than six tons of edible figs were prepared for market, as the result of the insect-life contained in less than 450 winter figs, where previously the fruit of thrifty Smyrna fig-trees had always fallen and perished while immature.]
—HOWARD *Smyrna Fig Culture in the United States (Year-book of the Department of Agriculture, 1900*, pp. 79-106.)

1687. ——— ——— *Profitable Result of Scientific Experiments—A Great Industry Resulting from Microscopic Research.*—Chemical analysis made by Professor Hilgard, of the University of California, showed that figs submitted to him by Mr. Roeding contained 1.42 per cent. more sugar than the best imported Smyrna figs. Samples which the writer has received are of excep-

tional edibility. The flavor is delicious and precisely comparable to that of the imported figs, except for the lack of the slight acidity noticed in those ordinarily bought on the market, and which is of a rather disagreeable quality. Wholesale grocers to whom the writer has shown samples speak with strong approval of their quality, and there seems little doubt that a great and profitable trade in figs of this grade can readily be gained in the United States. . . . But this feature by no means comprises all the possibilities of the industry. America will compete with the Mediterranean countries in the open markets of the world. The character of the product, even of this first year's crop, shows it to be superior to the Oriental product, both from chemical analysis and from expert opinion. . . . Cleanliness in packing, prevention of the disgusting worms so often found in the imported Smyrna figs, and other similar points will be carefully attended to by American packers. . . . The right varieties [of trees] will be planted by the thousands during the coming year, and in four or five years will be producing substantial crops. [See FIG, SMYRNA.]—HOWARD *Smyrna Fig Culture in the United States (Year-book of the Department of Agriculture, 1900*, pp. 79-106).

1688. INSECTS FLEEING BEFORE WIND—*Dragon-flies and the Pampero.*—The pampero is a dry, cold wind, exceedingly violent. It bursts on the plains very suddenly, and usually lasts only a short time, sometimes not more than ten minutes; it comes irregularly, and at all seasons of the year, but is most frequent in the hot season, and after exceptionally sultry weather. It is in summer and autumn that the large dragon-flies appear; not with the wind, but —and this is the most curious part of the matter—in advance of it; and inasmuch as these insects are not seen in the country at other times, and frequently appear in seasons of prolonged drought, when all the marshes and watercourses for many hundreds of miles are dry, they must of course traverse immense distances, flying before the wind at a speed of seventy or eighty miles an hour. On some occasions they appear almost simultaneously with the wind, going by like a flash, and instantly disappearing from sight. You have scarcely time to see them before the wind strikes you.—HUDSON *Naturalist in La Plata*, ch. 9, p. 131. (C. & H., 1895.)

1689. INSECURITY, SENSE OF, PRODUCED BY EARTHQUAKE—*The "Solid Ground" Quivers Like Thin Ice.*—February 20th, 1835.—This day has been memorable in the annals of Valdivia for the most severe earthquake experienced by the oldest inhabitant. I happened to be on shore, and was lying down in the wood to rest myself. It came on suddenly, and lasted two minutes, but the time appeared much longer. The rocking of the ground was very sensible. The undulations appeared to my companion and myself to come from due east, whilst others thought they proceeded from southwest: this shows how difficult it sometimes is to perceive the direction of the vibrations. There was no difficulty in standing upright, but the motion made me almost giddy: it was something like the movement of a vessel in a little cross-ripple, or still more like that felt by a person skating over thin ice, which bends under the weight of his body. A bad earthquake at once destroys our oldest associations: the earth, the very emblem of solidity, has moved beneath our feet like a thin crust over a fluid—one second of time has created in the mind a strange idea of insecurity, which hours of reflection would not have produced.—DARWIN *Naturalist's Voyage around the World*, ch. 14, p. 301. (A., 1898.)

1690. INSENSIBILITY DUE TO ABSENCE OF MIND—*Power of Mental Absorption over the Bodily Life.*—Archimedes, it is well known, was so absorbed in geometrical meditation that he was first aware of the storming of Syracuse by his own death-wound, and his exclamation on the entrance of the Roman soldiers was: *Noli turbare circulos meos!* In like manner Joseph Scaliger, the most learned of men, when a Protestant student in Paris was so engrossed in the study of Homer that he became aware of the massacre of St. Bartholomew, and of his own escape, only on the day subsequent to the catastrophe. The philosopher Carneades was habitually liable to fits of meditation so profound that, to prevent him sinking from inanition, his maid found it necessary to feed him like a child. And it is reported of Newton that, while engaged in his mathematical researches, he sometimes forgot to dine. Cardan, one of the most illustrious of philosophers and mathematicians, was once, upon a journey, so lost in thought that he forgot both his way and the object of his journey. To the questions of his driver whether he should proceed, he made no answer; and when he came to himself at nightfall, he was surprised to find the carriage at a standstill, and directly under a gallows. The mathematician Vieta was sometimes so buried in meditation that for hours he bore more resemblance to a dead person than to a living, and was then wholly unconscious of everything going on around him. On the day of his marriage the great Budæus forgot everything in his philological speculations, and he was only awakened to the affairs of the external world by a tardy embassy from the marriage-party, who found him absorbed in the composition of his "Commentarii."—HAMILTON *Metaphysics*, lect. 14, p. 180. (G. & L., 1859.)

1691. INSIGHT, SCIENTIFIC, ENLARGED—*Mental Advance Attends Opening of the Pacific.*—The Sandwich Islands, Papua or New Guinea, and some portions of

New Holland were all discovered in the early half of the sixteenth century. . . . The Pacific no longer appeared as it had done to Magellan, a desert waste; it was now animated by islands, which, however, for want of exact astronomical observations, appeared to have no fixed position, but floated from place to place over the charts. The Pacific remained for a long time the exclusive theater of the enterprises of the Spaniards and Portuguese. It was not until the Dutch power acquired the ascendency in the Moluccas that Australia began to emerge from its former obscurity and to assume a definite form in the eyes of geographers. In a short space of time and in continuous connection, two-thirds of the earth's surface were opened to the apprehension of men, in consequence of the suddenly awakened desire to reach the wide, the unknown, and the remote regions of our globe.

An enlarged insight into the nature and the laws of physical forces, into the distribution of heat over the earth's surface, the abundance of vital organisms and the limits of their distribution, was developed simultaneously with this extended knowledge of land and sea.—HUMBOLDT *Cosmos*, vol. ii, pt. ii. p. 272. (H., 1897.)

1692. INSPIRATION NEEDED IN SCIENCE—*Knowledge Supplemented by Reflection.*—In his efforts to cross the common bourn of the known and the unknown, the effective force of the man of science must depend, to a great extent, upon his acquired knowledge. But knowledge alone will not do; a stored memory will not suffice; inspiration must lend its aid. Scientific inspiration, however, is usually, if not always, the fruit of long reflection—of patiently "intending the mind," as Newton phrased it, and as Copernicus, Newton, and Darwin practised it, until outer darkness yields a glimmer, which in due time opens out into perfect intellectual day.—TYNDALL *Fragments of Science,* vol. i, ch. 5, p. 132. (A., 1897.)

1693. INSPIRATION OF GENIUS—*Compared to the Gift of the Spirit (John iii. 8)—The Joy of Discovery—The "Eureka" of Archimedes.*—Working backwards from a limited number of phenomena, genius, by its own expansive force, reaches a conception which covers them all. There is no more wonderful performance of the intellect than this; but we can render no account of it. Like the Scriptural gift of the Spirit, no man can tell whence it cometh. The passage from fact to principle is sometimes slow, sometimes rapid, and at all times a source of intellectual joy. When rapid, the pleasure is concentrated and becomes a kind of ecstasy or intoxication. To any one who has experienced this pleasure, even in a moderate degree, the action of Archimedes when he quitted the bath, and ran naked, crying "Eureka!" through the streets of Syracuse, becomes intelligible.—TYNDALL *Lectures on Light,* lect. 2, p. 47. (A., 1898.)

1694. INSTABILITY OF THE EARTH—*The Eruption of Krakatoa Felt around the Globe—The Dust Thrown into the Atmosphere Would Bury Washington Monument.*—The eruption of Krakatoa occurred in 1883, and it will be remembered the air-wave started by the explosion was felt around the globe, and that probably owing to the dust and water-vapor blown into the atmosphere, the sunsets even in America became of that extraordinary crimson we all remember [as occurring at that time]; and, coincidently, that dim reddish halo made its appearance about the sun the world over. . . . Very careful estimates of the amount of ashes ejected have been made; and tho most of the heavier particles are known to have fallen into the sea within a few miles, a certain portion—the lightest—was probably carried by the explosion far above the lower strata of the atmosphere, to descend so slowly that some of it may still be there. Of this lighter class the most careful estimates must be vague; but according to the report of the official investigation by the Dutch Government, that which remained floating is something enormous. An idea of its amount may be gained by supposing these impalpable and invisible particles to condense again from the upper sky, and to pour down on the highest edifice in the country, the Washington Monument. If the dust were allowed to spread out on all sides, till the pyramidal slope was so flat as to be permanent, the capstone of the monument would not only be buried before the supply was exhausted, but buried as far below the surface as that pinnacle is now above it.—LANGLEY *New Astronomy,* ch. 6, p. 181. (H. M. & Co., 1896.)

1695. INSTINCT AND REASON—*Human Organism Like Keyed Instrument—Lower Animal Like Barrel-organ—Caterpillar and Its Hammock.*—Thus, then, while the human organism may be likened to a keyed instrument, from which any music it is capable of producing can be called forth at the will of the performer, we may compare a bee or any other insect to a barrel-organ, which plays with the greatest exactness a certain number of tunes that are set upon it, but can do nothing else. The following fact, mentioned by Pierre Huber, affords a curious example of the purely automatic nature of instinctive action:

There is a caterpillar that makes a very complicated hammock, the construction of which may be divided into six stages. One of these caterpillars which had completed its own hammock, having been transferred to another carried only to its third stage, completed this also by reperforming the fourth, fifth, and sixth stages. But another caterpillar taken out of a hammock which had been only carried to its third stage, and put into one already completed, appeared much embarrassed, and seemed forced to go back to the point at which it had itself left off, executing anew the fourth, fifth, and

sixth stages which had been already wrought out.—CARPENTER *Mental Physiology*, bk. i, ch. 2, p. 61. (A., 1900.)

1696. INSTINCT DYING OF INANITION—*Men without the Desire of Hunting.*—The latter [hunting] instinct is easily restricted by habit to certain objects, which become legitimate "game," while other things are spared. If the hunting instinct be not exercised at all, it may even entirely die out, and a man may enjoy letting a wild creature live, even tho he might easily kill it. Such a type is now becoming frequent. —JAMES *Psychology*, vol. ii, ch. 24, p. 415. (H. H. & Co., 1899.)

1697. INSTINCT FOLLOWS INFLEXIBLE ROUTINE—*The Sphex-wasp.*—The butcher-wasps paralyze their prey [that it may become food for their larvæ]. Fabre removed from a so-called sphex-wasp a killed grasshopper, which it was conveying to its nest and had momentarily laid down at the mouth of the burrow—as these insects always do on returning with prey, in order to see that nothing has intruded into the burrow during their absence. Fabre carried the dead or paralyzed grasshopper to a considerable distance from the hole. On coming out the insect searched about until it found its prey. It then again carried it to the mouth of its burrow, and again laid it down while it once more went in to see that all was right at home. Again Fabre removed the grasshopper, and so on for forty times in succession—the sphex never omitting to go through its fixed routine of examining the interior of its burrow every time that it brought the prey to its mouth.—ROMANES *Animal Intelligence*, ch. 4, p. 181. (A., 1899.)

1698. INSTINCT INDEPENDENT OF EDUCATION—*Automatic Adaptation to Ends.*—Instinct is usually defined as the faculty of acting in such a way as to produce certain ends, without foresight of the ends, and without previous education in the performance. That instincts, as thus defined, exist on an enormous scale in the animal kingdom needs no proof. They are the functional correlatives of structure. With the presence of a certain organ goes, one may say, almost always a native aptitude for its use. [In his work on "Instinct," P. A. Chadbourne says]:

"Has the bird a gland for the secretion of oil? She knows instinctively how to press the oil from the gland, and apply it to the feather. Has the rattlesnake the grooved tooth and gland of poison? He knows without instruction how to make both structure and function most effective against his enemies. Has the silkworm the function of secreting the fluid silk? At the proper time she winds the cocoon such as she has never seen, as thousands before have done, and thus, without instruction, pattern, or experience, forms a safe abode for herself in the period of transformation. Has the hawk talons? She knows by instinct how to wield them effectively against the helpless quarry."—JAMES *Psychology*, vol. ii, ch. 24, p. 383. (H. H. & Co., 1899.)

1699. INSTINCT IN MAN—*Existing, but Controlled.*—It is often said that man is distinguished from the lower animals by having a much smaller assortment of native instincts and impulses than they, but this is a great mistake. . . . If we compare him with the mammalia, we are forced to confess that he is appealed to by a much larger array of objects than any other mammal; that his reactions on these objects are characteristic and determinate in a very high degree. The monkeys, and especially the anthropoids, are the only beings that approach him in their analytic curiosity and width of imitativeness. His instinctive impulses, it is true, get overlaid by the secondary reactions due to his superior reasoning power; but thus man loses the simply instinctive demeanor. But the life of instinct is only disguised in him, not lost.—JAMES *Talks to Teachers*, ch. 6, p. 43. (H. H. & Co., 1900.)

1700. ——— ——— *Less Imperious than in the Inferior Animals—Differences Exceed Resemblances—The Migrating Impulse.*—To measure the differences between beast and man is really more difficult than tracing their resemblances. One plain mark of the higher intellectual rank of man is that he is less dependent on instinct than the animals which migrate at a fixed season, or build nests of a fixed and complicated pattern peculiar to their kind. Man has some instincts plainly agreeing with those of inferior animals, such as the child's untaught movements to ward off danger, and the parental affection which preserves the offspring during the first defenseless period of life. But if man were possessed by a resistless longing to set off wandering southward before winter, or to build a shelter of boughs laid in a particular way, this would be less beneficial to his species than the use of intelligent judgment adapting his actions to climate, supply of food, danger from enemies, and a multitude of circumstances differing from district to district, and changing from year to year.—TYLOR *Anthropology*, ch. 2, p. 50. (A., 1899.)

1701. INSTINCT, LIMITATIONS OF—*Bees Know Locality Rather than Hive.*—Mr. George Turner found that when he removed a beehive only a yard or two from its accustomed site, the bees, on returning home, flew in swarms around the latter, and for a long time were unable to find the hive. And several other similar cases might be adduced. Lastly, Thompson says:

It is highly remarkable that they [bees] know their hive more from its locality than from its appearance, for, if it be removed during their absence and a similar one be substituted, they enter the strange one. If the position of a hive be changed, the bees

for the first day take no distant flight till they have thoroughly scrutinized every object in its neighborhood.—ROMANES *Animal Intelligence*, ch. 4, p. 149. (A., 1899.)

1702. ——— ——— *Dog Tries To Bury Food under Carpet—Automatic Action without Purpose—Transitoriness of Impulse.*—I have observed a Scotch terrier, born on the floor of a stable in December, and transferred six weeks later to a carpeted house, make, when he was less than four months old, a very elaborate pretense of burying things, such as gloves, etc., with which he had played till he was tired. He scratched the carpet with his forefeet, dropped the object from his mouth upon the spot, and then scratched all about it (with both fore- and hind-feet, if I remember rightly), and finally went away and let it lie. Of course the act was entirely useless. I saw him perform it at that age, some four or five times, and never again in his life. The conditions were not present to fix a habit which should last when the prompting instinct died away. But suppose meat instead of a glove, earth instead of a carpet, hunger-pangs instead of a fresh supper a few hours later, and it is easy to see how this dog might have got into a habit of burying superfluous food, which might have lasted all his life. Who can swear that the strictly instinctive part of the food-burying propensity in the wild *Canidæ* may not be as short-lived as it was in this terrier?—JAMES *Psychology*, vol. ii, ch. 24, p. 399. (H. H. & Co., 1899.)

1703. INSTINCT, MATERNAL, OF THE SPIDER—The courage and rapacity of spiders as a class are too well and generally known to require special illustration. One instance, however, may be quoted to show the strength of their maternal emotions. Bonnet threw a spider with her bag of eggs into the pit of an ant-lion. The latter seized the eggs and tore them away from the spider; but altho Bonnet forced her out of the pit she returned, and chose to be dragged in and buried alive rather than leave her charge.—ROMANES *Animal Intelligence*, ch. 6, p. 205. (A., 1899.)

1704. INSTINCTS COMPLEX — *Diving Spider—Carrying Air to Its Watery Home.*—[The] strangest of all [spiders is] the *Argyroneta* that has its luminous dwelling at the bottom of streams; and just as a mason carries bricks and mortar to its building, so does this spider carry down bubbles of air from the surface to enlarge its mysterious house in which it lays its eggs and rears its young. Community of descent must be supposed of species having such curious and complex instincts; but how came these feeble creatures, unable to transport themselves over seas and continents like the aerial gossamer, to be so widely distributed and inhabiting regions with such different conditions? This can only be attributed to the enormous antiquity of the species.—HUDSON *Naturalist in La Plata*, ch. 14, p. 195. (C. & H., 1895.)

1705. INSTINCTS INNATE — *Young Animals Follow Ancestral Habits without Instruction.*—Among the lower animals, young ones taken from the litter or the nest and brought up under conditions wholly removed from the teaching of their parents, whether by imitation or otherwise, will reproduce exactly all those habits of their race which belong to their natural modes of life. Many of these habits—perhaps it may be safely said all of them—imply ideas—that is to say, they imply instincts; and instincts are in the nature of ideas—that is to say, they belong to the phenomena of mind. And of this there is another indication in a fact which at first sight may seem trivial or irrelevant. It has been often said that one great difficulty in reasoning on this subject is the inaccessibility to observation of the mental condition of all infant creatures. But even if this were more true than it really is there are some creatures, not low in the scale of creation, of which it may be said that, comparatively, they have no infancy at all. These are the gallinaceous birds in general, and some species in particular. They come forth from the egg perfect miniatures of their parents, and with minds as fully equipped with parental instincts as their bodies are provided with feathers or their wings with quills. Antecedent to all experience of injury they exhibit fear, and not only fear, but fear of the proper objects. They will flee when they see a hawk, and they will carefully avoid a stinging insect. In Europe the young of the wood-grouse or gelinotte are able to fly from the moment they break the shell.—ARGYLL *Reign of Law*, ch. 6, p. 176. (Burt.)

1706. INSTINCTS, NATURAL, FOLLOWED IN DOMESTICATION—An animal in domesticity, says M. F. Cuvier, is not essentially in a different situation, in regard to the feeling of restraint, from one left to itself. It lives in society without constraint, because, without doubt, it was a social animal; and it conforms itself to the will of man because it had a chief to which, in a wild state, it would have yielded obedience. There is nothing in its new situation that is not conformable to its propensities; it is satisfying its wants by submission to a master, and makes no sacrifice of its natural inclinations. All the social animals when left to themselves form herds more or less numerous; and all the individuals of the same herd know each other, are mutually attached, and will not allow a strange individual to join them. In a wild state, moreover, they obey some individual, which by its superiority has become the chief of the herd. Our domestic species had originally this sociability of disposition, and no solitary species, however easy it may be to tame it, has yet afforded true domestic races. We me. ly, therefore, develop to our own

advantage propensities which propel the individuals of certain species to draw near to their fellows.—LYELL *Principles of Geology,* bk. iii, ch. 35, p. 596. (A., 1854.)

1707. INSTINCTS OF LABOR BLIND AND RECKLESS—*Deadly Trades Never Lack Recruits.*—There are certain results for the attainment of which the natural instincts of individual men not only may be trusted, but must be trusted as the best and indeed the only guide. There are other results of which as a rule those instincts will take no heed whatever, and for the attainment of which, if they are to be attained at all, the higher faculties of our nature must impose their will in authoritative expressions of human law. In all that wide circle of operations which have for their immediate result the getting of wealth there is a sagacity and a cunning in the instincts of labor and in the love of gain compared with which all legislative wisdom is ignorance and folly. But the instincts of labor, having for their conscious purpose the acquisition of wealth, are instincts which, under the stimulus and necessities of modern society, are blind to all other results whatever. They override even the love of life; they silence even the fear of death. Trades in which the laborers never reach beyond middle life—trades in which the work is uniformly fatal within a few years—trades in which those who follow them are liable to loathsome and torturing disease—all are filled by the enlistment of an unfailing series of recruits. If, therefore, there be some things desirable or needful for a community other than the acquisition of wealth—if mental ignorance and physical degeneracy be evils dangerous to social and political prosperity, then these results cannot and must not be trusted to the instincts of individual men. And why? Because the few motives which bear upon them, and which consequently determine their conduct, have become almost as imperious as the motives which determine the conduct of the lower animals.—ARGYLL *Reign of Law,* ch. 7, p. 213. (Burt.)

1708. INSTINCTS VS. IMPULSES—*Memory and Reason Regulate Human Impulses—Blindness of Mere Instincts.*—Nothing is commoner than the remark that man differs from lower creatures by the almost total absence of instincts, and the assumption of their work in him by "reason." . . . Man has a far greater variety of impulses than any lower animal; and any one of these impulses taken in itself is as "blind" as the lowest instinct can be; but owing to man's memory, power of reflection, and power of inference, they come each one to be felt by him after he has once yielded to them and experienced their results in connection with a foresight of those results. In this condition an impulse acted out may be said to be acted out, in part at least, for the sake of its results.—JAMES *Psychology,* vol. ii, ch. 24, p. 389. (H. H. & Co., 1899.)

1709. INSTRUCTION MIGHT SAVE LIFE—*Need of Object-lessons—The Miner's Safety-lamp.*—Sir Humphry Davy, after having assured himself of the action of wire gauze [in cutting off a gas-flame], applied it to the construction of a lamp which should enable the miner to carry his light into an explosive atmosphere. He surrounded a common oil-lamp by a cylinder of wire gauze. So long as this lamp is fed by pure air the flame burns with the ordinary brightness of an oil flame; but when the miner comes into an atmosphere containing "fire-damp" his flame enlarges and becomes less luminous. This enlargement of the flame ought to be taken as a warning to retire. Still, tho a continuous explosive atmosphere extends from the air outside through the meshes of the gauze to the flame within, ignition is not propagated across the gauze. A defect in the gauze, the destruction of the wire at any point by oxidation, would cause explosion. The rapid motion of the lamp through the air, or the impact of a "blower" upon the lamp, might also force the flame through the meshes. In short, a certain amount of intelligence and caution is necessary in using the lamp. This intelligence, unhappily, is not always possessed, nor is this caution always exercised, and the consequence is that even with the safety-lamp explosions still occur. Before permitting a man or boy to enter a mine would it not be well to place these results, by experiment, visibly before him? Mere advice will not enforce caution; but let the miner have the physical image of what he is to expect clearly and vividly before his mind and he will find it a restraining force and a monitory influence long after the effect of cautioning words has passed away.—TYNDALL *Heat a Mode of Motion,* lect. 9, p. 262. (A., 1900.)

1710. INTELLECT, BOUNDARY-LINE OF—*Ordinary Lessons of Science Fail.*—The reverse process of the production of motion by consciousness is equally unpresentable to the mind. We are here, in fact, on the boundary-line of the intellect, where the ordinary canons of science fail to extricate us. If we are true to these canons we must deny to subjective phenomena all influence on physical processes. The mechanical philosopher, as such, will never place a state of consciousness and a group of molecules in the relation of mover and moved. Observation proves them to interact; but in passing from the one to the other we meet a blank which the logic of deduction is unable to fill.—TYNDALL *Fragments of Science,* vol. ii, ch. 15, p. 408. (A., 1900.)

1711. INTELLECT DEVELOPED BY STRUGGLE FOR LIFE AMONG MEN—*A Struggle of Brains.*—The result of the struggle for life is that in the long run that which is better because more perfect conquers that which is weaker and imperfect. In human life, however, this struggle for

life will ever become more and more of an intellectual struggle, not a struggle with weapons of murder. The organ which above all others in man becomes more perfect by the ennobling influence of natural selection is the brain. The man with the most perfect understanding, not the man with the best revolver, will in the long run be victorious; he will transmit to his descendants the qualities of the brain which assisted him in the victory. Thus then we may justly hope, in spite of all the efforts of retrograde forces, that the progress of mankind towards freedom, and thus to the utmost perfection, will, by the happy influence of natural selection, become more and more a certainty.—HAECKEL *History of Creation*, vol. i, ch. 7, p. 179. (K. P. & Co., 1899.)

1712. INTELLECT HAS OUTSTRIPPED HEART—There can be little doubt that in respect of justice and kindness the advance of civilized man has been less marked than in respect of quick-wittedness.—FISKE *Destiny of Man*, ch. 10, p. 74. (H. M. & Co., 1900.)

1713. INTELLECT, LIMITATIONS OF—*Mathematical Faculty Defective among Savages.*—We have ample evidence that in all the lower races of man what may be termed the mathematical faculty is either absent or, if present, quite unexercised. The bushmen and the Brazilian wood-Indians are said not to count beyond two. Many Australian tribes only have words for one and two, which are combined to make three, four, five, or six, beyond which they do not count. The Damaras of South Africa only count to three; and Mr. Galton gives a curious description of how one of them was hopelessly puzzled when he had sold two sheep for two sticks of tobacco each and received four sticks in payment. He could only find out that he was correctly paid by taking two sticks and then giving one sheep, then receiving two sticks more and giving the other sheep.—WALLACE *Darwinism*, ch. 15, p. 312. (Hum., 1889.)

1714. INTELLECT OF MAN CONQUERS THE EARTH—*Superiority to Local and Climatic Changes.*—Man differs essentially from all other mammals in this respect: that whereas any important adaptation to new conditions can be effected in them only by a change in bodily structure, man is able to adapt himself to much greater changes of conditions by a mental development leading him to the use of fire, of tools, of clothing, of improved dwellings, of nets and snares, and of agriculture. By the help of these, without any change whatever in his bodily structure, he has been able to spread over and occupy the whole earth; to dwell securely in forest, plain, or mountain; to inhabit alike the burning desert or the arctic wastes; to cope with every kind of wild beast, and to provide himself with food in districts where, as an animal trusting to Nature's unaided productions, he would have starved.—WALLACE *Darwinism*, ch. 15, p. 307. (Hum., 1889.)

1715. INTELLECT REQUIRED TO MAKE A UNIVERSE WHICH INTELLECT IS REQUIRED TO COMPREHEND—There is a singular lack of logic, as it seems to me, in the views of the materialistic naturalists. While they consider classification, or, in other words, their expression of the relations between animals or between physical facts of any kind, as the work of their intelligence, they believe the relations themselves to be the work of physical causes. The more direct inference surely is, that if it requires an intelligent mind to recognize them it must have required an intelligent mind to establish them. These relations existed before man was created; they have existed ever since the beginning of time; hence what we call the classification of facts is not the work of his mind in any direct original sense, but the recognition of an intelligent action prior to his own existence.—AGASSIZ *Geological Sketches*, ser. i, ch. 1, p. 22. (H. M. & Co., 1896.)

1716. INTELLIGENCE AND BARBARISM COEXISTING—*The Old Man of Cromagnon—Cave-dwellers Like American Indians.*—Professor Broca, who seems by no means disinclined to favor a simian origin for men, has the following general conclusions, which refer to the Cromagnon skulls: "The great volume of the brain, the development of the frontal region, the fine elliptical profile of the anterior portion of the skull, and the orthognathous form of the upper facial region are incontestably evidences of superiority which are met with usually only in the civilized races. On the other hand, the great breadth of face, the alveolar prognathism, the enormous development of the ascending ramus of the lower jaw, the extent and roughness of the muscular insertions, especially of the masticatory muscles, give rise to the idea of a violent and brutal race." He adds that this apparent antithesis, seen also in the limbs as well as in the skull, accords with the evidence furnished by the associated weapons and implements of a rude hunter-life, and at the same time of no mean degree of taste and skill in carving and other arts. He might have added that this is precisely the antithesis seen in the American tribes, among whom art and taste of various kinds, and much that is high and spiritual even in thought, coexisted with barbarous modes of life and intense ferocity and cruelty. The god and the devil were combined in these races, but there was nothing of the mere brute.—DAWSON *Facts and Fancies in Modern Science*, lect. 4, p. 162. (A. B. P. S.)

1717. INTELLIGENCE AND ENTERPRISE OF PRIMITIVE MAN—Paleolithic implements abound in the drift gravels; the surface is strewn with flint flakes and frag-

ments of flint implements; and at the present time it [Brandon] is the only place in England where gun-flints are still made. For this purpose one particular layer of flint is found to be peculiarly well adapted, on account of its hardness and fineness of grain, while another layer, less suitable for gun-flints, is known as "wall-stone," being much used for building purposes. Now it is interesting to find that even in very early times the merits of the gun-flint layer were well known and appreciated; for altho there is abundance of flint on the surface the ancient flint-men sank their shafts down past the layer of "wall-stone," which occurs at a depth of 19½ feet, to the gun-flint layer, which at the spot in question is 39 feet deep.—AVEBURY *Prehistoric Times*, ch. 4, p. 78. (A., 1900.)

1718. INTELLIGENCE IN LOWER FORMS OF LIFE—*Worms Show Method in Plugging Up Their Burrows—Difficulty of Drawing Dividing Line between the Intelligent and the Automatic.*—If we consider the cases [specified] we can hardly escape from the conclusion that worms show some degree of intelligence in their manner of plugging up their burrows. Each particular object is seized in too uniform a manner, and from causes which we can generally understand, for the result to be attributed to mere chance. That every object has not been drawn in by its pointed end may be accounted for by labor having been saved through some being inserted by their broader or thicker ends. No doubt worms are led by instinct to plug up their burrows; and it might have been expected that they would have been led by instinct how best to act in each particular case, independently of intelligence. We see how difficult it is to judge whether intelligence comes into play, for even plants might sometimes be thought to be thus directed; for instance, when displaced leaves redirect their upper surfaces towards the light by extremely complicated movements and by the shortest course. With animals actions appearing due to intelligence may be performed through inherited habit without any intelligence, altho aboriginally thus acquired. Or the habit may have been acquired through the preservation and inheritance of beneficial variations of some other habit; and in this case the new habit will have been acquired independently of intelligence throughout the whole course of its development. There is no a priori improbability in worms having acquired special instincts through either of these two latter means. Nevertheless, it is incredible that instincts should have been developed in reference to objects, such as the leaves or petioles of foreign plants, wholly unknown to the progenitors of the worms which act in the described manner. Nor are their actions so unvarying or inevitable as are most true instincts.—DARWIN *The Formation of Vegetable Mould*, ch. 2, p. 26. (Hum., 1887.)

1719. INTELLIGENCE OF ANIMALS—*Known to Man Only by Inference.*—By mind we may mean two very different things, according as we contemplate it in our own individual selves or in other organisms. For if we contemplate our own mind we have an immediate cognizance of a certain flow of thoughts or feelings, which are the most ultimate things, and indeed the only things of which we are cognizant. But if we contemplate mind in other persons or organisms we have no such immediate cognizance of thoughts or feelings. In such cases we can only infer the existence and the nature of thoughts and feelings from the activities of the organisms which appear to exhibit them. . . . All our knowledge of their operations is derived, as it were, through the medium of ambassadors, these ambassadors being the activities of the organism. Hence it is evident that in our study of animal intelligence we are wholly restricted to the objective method. Starting from what I know subjectively of the operations of my own individual mind and the activities which in my own organism they prompt, I proceed by analogy to infer from the observable activities of other organisms what are the mental operations that underlie them.—ROMANES *Animal Intelligence*, int., p. 1. (A., 1899.)

1720. ——— ——— *Limitations of—Ceaseless Surprise of the Casarita—Vain Toil without Understanding.*—Another and smaller species of *Furnarius (F. cunicularius)* resembles the oven-bird in the general reddish tint of its plumage, in a peculiar shrill reiterated cry, and in an odd manner of running by starts. From its affinity, the Spaniards call it "casarita" (or little house-builder). . . . The casarita builds its nest at the bottom of a narrow cylindrical hole, which is said to extend horizontally to nearly six feet underground. Several of the country people told me that when boys they had attempted to dig out the nest, but had scarcely ever succeeded in getting to the end of the passage. The bird chooses any low bank of firm sandy soil by the side of a road or stream. Here (at Bahia Blanca) the walls round the houses are built of hardened mud; and I noticed that one, which enclosed a courtyard where I lodged, was bored through by round holes in a score of places. On asking the owner the cause of this he bitterly complained of the little casarita, several of which I afterwards observed at work. It is rather curious to find how incapable these birds must be of acquiring any notion of thickness, for altho they were constantly flitting over the low wall they continued vainly to bore through it, thinking it an excellent bank for their nests. I do not doubt that each bird, as often as it came to daylight on the opposite side, was greatly surprised at the marvelous fact.—DARWIN *Naturalist's Voyage around the World*, ch. 5, p. 95. (A., 1898.)

1721. ——— ——— *Modification of Instinct in Birds—Jackdaws Build Buttress for Their Nest.*—A pair of jackdaws endeavored to construct their nest in one of the small windows that lighted the spiral staircase of an old church-tower. As is usual, however, in such windows, the sill sloped inwards with a considerable inclination; and, consequently, there being no level base for the nest, as soon as a few sticks had been laid, and it was beginning to acquire weight, it slid down. This seems to have happened two or three times; nevertheless the birds clung with great pertinacity to the site they had selected, and at last devised a most ingenious method of overcoming the difficulty. Collecting a great number of sticks, they built up a sort of cone upon the staircase, the summit of which rose to the level of the window-sill and afforded the requisite support to the nest; this cone was not less than six feet high, and so large at its base as quite to obstruct the passage up the staircase; yet, notwithstanding the large amount of material which it contained, it was known to have been constructed within four or five days. Now as this was a device quite foreign to the natural habit of the bird, and only hit upon after the repeated failure of its ordinary method of nest-building, the curious adaptation of means to ends which it displayed can scarcely be regarded in any other light than as proceeding from a design in the minds of the individuals who executed it.—CARPENTER *Mental Physiology,* ch. 2, p. 86. (A., 1900.)

1722. ——— ——— *The Ants Rank Near to Man—Superior to the Anthropoid Apes.*—The anthropoid apes no doubt approach nearer to man in bodily structure than do any other animals; but when we consider the habits of ants, their social organization, their large communities and elaborate habitations; their roadways, their possession of domestic animals, and even, in some cases, of slaves, it must be admitted that they have a fair claim to rank next to man in the scale of intelligence.—AVEBURY *Ants, Bees, and Wasps,* ch. 1, p. 1. (A., 1900.)

1723. ——— ——— *The Cat—Skill in Dealing with Mechanical Contrivances.*—I have received some half-dozen instances of this display of intelligence [the opening of a thumb-latch] on the part of cats. These instances are all such precise repetitions of one another that I conclude the fact to be one of tolerably ordinary occurrence among cats, while it is certainly very rare among dogs. I may add that my own coachman once had a cat which, certainly without tuition, learned thus to open a door that led into the stables from a yard into which looked some of the windows of the house. Standing at these windows when the cat did not see me, I have many times witnessed her *modus operandi.* Walking up to the door with a most matter-of-course kind of air, she used to spring at the half-hoop handle just below the thumb-latch. Holding on to the bottom of this half-loop with one forepaw, she then raised the other to the thumbpiece, and, while depressing the latter, finally with her hind legs scratched and pushed the doorposts so as to open the door. Precisely similar movements are described by my correspondents as having been witnessed by them.—ROMANES *Animal Intelligence,* ch. 14, p. 420. (A., 1899.)

1724. ——— ——— *The Elephant—Rapid Domestication—Limited Attainment—Education Early Becomes Complete.*—No animal affords a more striking illustration of the principal points which I have been endeavoring to establish than the elephant; for, in the first place, the wonderful sagacity with which he accommodates himself to the society of man, and the new habits which he contracts, are not the result of time, nor of modifications produced in the course of many generations. [Tho] these animals will breed in captivity, . . . it has always been the custom, as the least expensive mode of obtaining them, to capture wild individuals in the forests, usually when full grown; and in a few years after they are taken—sometimes, it is said, in the space of a few months—their education is completed.

Had the whole species been domesticated from an early period in the history of man, like the camel, their superior intelligence would, doubtless, have been attributed to their long and familiar intercourse with the lord of the creation, but we know that a few years is sufficient to bring about this wonderful change of habits, and altho the same individual may continue to receive tuition for a century afterwards, yet it makes no farther progress in the development of its faculties.—LYELL *Principles of Geology,* bk. iii, ch. 35, p. 598. (A., 1854.)

1725. ——— ——— *The Shepherd Dog—Story of the "Ettrick Shepherd"—Recovery of Lost Sheep.*—The following is a very remarkable case of this kind, which occurred in the experience of James Hogg, the "Ettrick Shepherd," the associate of Walter Scott and Christopher North:

Mr. Hogg goes on to narrate the following, among other remarkable exploits, in illustration of Sirrah's sagacity. About seven hundred lambs, which were at once under his care at weaning-time, broke up at midnight, and scampered off in three divisions across the hills, in spite of all that the shepherd and an assistant lad could do to keep them together. "Sirrah," cried the shepherd in great affliction, "my man, they're a' awa." The night was so dark that he did not see Sirrah; but the faithful animal had heard his master's words—words such as of all others were sure to set him most on the alert; and without any delay, he silently set off in quest of the recreant flock. Meanwhile the shepherd and his companion did not fail to do all that was in

their power to recover their lost charge; they spent the whole night in scouring the hills for miles around, but of neither the lambs nor Sirrah could they obtain the slightest trace. "It was the most extraordinary circumstance," says the shepherd, "that had ever occurred in the annals of the pastoral life. We had nothing for it (day having dawned) but to return to our master, and inform him that we had lost his whole flock of lambs, and knew not what was become of one of them. On our way home, however, we discovered a body of lambs at the bottom of a deep ravine, called the Flesh Clench, and the indefatigable Sirrah standing in front of them, looking all around for some relief, but still standing true to his charge. The sun was then up; and when we first came in view of them, we concluded that it was one of the divisions of the lambs, which Sirrah had been unable to manage until he came to that commanding situation. But what was our astonishment, when we discovered by degrees that not one lamb of the whole flock was wanting! How he had got all the divisions collected in the dark is beyond my comprehension. The charge was left entirely to himself, from midnight until the rising of the sun; and if all the shepherds in the forest had been there to have assisted him, they could not have effected it with greater propriety. All that I can further say is that I never felt so grateful to any creature below the sun as I did to my honest Sirrah that morning."—CARPENTER *Mental Physiology*, ch. 2, p. 102. (A., 1900.)

1726. ——— ——— *The Wasp—Taking Bearings—Starting Fresh When at Fault.*—A specimen of *Polistes carnifex* [or sand-wasp] was hunting about for caterpillars in my garden. I found one about an inch long, and held it out towards it on the point of a stick. It seized it immediately, and commenced biting it from head to tail, soon reducing the soft body to a mass of pulp. It rolled up about one-half of it into a ball, and prepared to carry it off. Being at the time amidst a thick mass of a fine-leaved climbing plant, it proceeded, before flying away, to take note of the place where it was leaving the other half. To do this, it hovered in front of it for a few seconds, then took small circles in front of it, then larger ones round the whole plant. I thought it had gone, but it returned again, and had another look at the opening in the dense foliage down which the other half of the caterpillar lay. It then flew away, but must have left its burden for distribution with its comrades at the nest, for it returned in less than two minutes, and, making one circle around the bush, descended to the opening, alighted on a leaf, and ran inside. The green remnant of the caterpillar was lying on another leaf inside, but not connected with the one on which the wasp alighted, so that in running in it missed it, and soon got hopelessly lost in the thick foliage. Coming out again, it took another circle, and pounced down on the same spot again, as soon as it came opposite to it. Three small seed-pods, which here grew close together, formed the marks that I had myself taken to note the place, and these the wasp seemed also to have taken as its guide, for it flew directly down to them, and ran inside; but the small leaf on which the fragment of caterpillar lay not being directly connected with any on the outside, it again missed it, and again got far away from the object of its search. It then flew out again, and the same process was repeated again and again. Always when in circling round it came in sight of the seed-pods, down it pounced, alighted near them, and recommenced its quest on foot. I was surprised at its perseverance, and thought it would have given up the search; but not so, it returned at least half a dozen times, and seemed to get angry, hurrying about with buzzing wings. At last it stumbled across its prey, seized it eagerly, and, as there was nothing more to come back for, flew straight off to its nest, without taking any further note of the locality. Such an action is not the result of blind instinct, but of a thinking mind; and it is wonderful to see an insect so differently constructed using a mental process similar to that of man.—ROMANES *Animal Intelligence*, ch. 4, p. 150. (A., 1899.)

1727. INTELLIGENCE OF HIGH ORDER—*Only Developed After Birth.*—When a creature's intelligence is high and its experience varied and complicated, the registration of all this experience in the nerve-centers of its offspring does not get accomplished before birth. There is not time enough. The most important registrations, such as those needed for breathing and swallowing and other indispensable acts, are fully effected; others, such as those needed for handling and walking, are but partially effected; others, such as those involved in the recognition of creatures not important as enemies or prey, are left still further from completion. Much is left to be done by individual experience after birth. The animal, when first born, is a baby dependent upon its mother's care. At the same time its intelligence is far more plastic, and it remains far more teachable, than the lower animal that has no babyhood.—FISKE *Through Nature to God*, pt. ii, ch. 7, p. 92. (H. M. & Co., 1900.)

1728. INTELLIGENCE REQUISITE FOR COOK—*Economy of Fuel.*—"I well know, from my own experience, how difficult it is to persuade cooks of this truth [of the utility of boiling-hot water], but it is so important that no pains should be spared in endeavoring to remove their prejudices and enlighten their understandings. This may be done most effectually in the case before us by a method I have several times put in practise with complete success. It is as follows: Take two equal boilers, containing

equal quantities of boiling hot water, and put into them two equal pieces of meat taken from the same carcass—two legs of mutton, for instance—and boil them during the same time. Under one of the boilers make a small fire, just barely sufficient to keep the water boiling hot, or rather just beginning to boil; under the other make as vehement a fire as possible, and keep the water boiling the whole time with the utmost violence. The meat in the boiler in which the water has been kept only just boiling hot will be found to be quite as well done as that in the other. It will even be found to be much better cooked, that is to say, tenderer, more juicy, and much higher flavored."—RUMFORD quoted by WILLIAMS in *Chemistry of Cookery*, ch. 2, p. 17. (A., 1900.)

1729. INTELLIGENCE SHOWN IN RELICS OF STONE AGE—*Language the True Mold of Mind.*—The flints and arrowheads, the celts and hammers, of early man are fossil intelligence; the remains of primitive arts and industries are petrified mind. But there is one mold into which mind has run more large and beautiful than any of these. When its contents are examined they carry us back not only to what men worked at with their hands, but to what they said to one another as they worked and what they thought as they spoke. That mold is language.—DRUMMOND *Ascent of Man*, p. 147. (J. P., 1900.)

1730. INTELLIGENCE THE FINAL VICTOR—*The Evolution of Mind.*—Nature is full of new departures; but never since time began was there anything approaching in importance that period when the slumbering animal brain broke into intelligence, and the creature first felt that it had a mind. From that dateless moment a higher and swifter progress of the world began. Henceforth, intelligence triumphed over structural adaptation. The wise were naturally selected before the strong. The mind discovered better methods, safer measures, shorter cuts. So the body learned to refer to it, then to defer to it. As the mind was given more to do, it enlarged and did its work more perfectly. Gradually the favors of evolution—exercise, alteration, differentiation, addition—which were formerly distributed promiscuously among the bodily organs—were now lavished mainly upon the brain. The gains accumulated with accelerating velocity; and by sheer superiority and fitness for its work the intellect rose to commanding power and entered into final possession of a monopoly which can never be disturbed.—DRUMMOND *Ascent of Man*, ch. 3, p. 116. (J. P., 1900.)

1731. INTEMPERANCE, DEBASING EFFECT OF—*Special Degradation of Woman—Moral Influence Defeated by Morbid Physical Craving.*—The debasing effect of continued alcoholic excess is, unfortunately, but too apparent. Cases like that of Hartley Coleridge, in which it seems only to excite the higher part of the intellectual and moral nature to an irregular activity, are extremely rare. Far more generally, while weakening the will and exciting the lower propensities, it blunts the moral sense also; and the wretched victim becomes so completely the slave of his tyrannical appetite for drink that he is ready to gratify it at any sacrifice. This moral degradation is perhaps even more marked in women than in men; for the drunkenness of the former (especially in the upper ranks of society) being usually secret—at least in the first instance—whilst in the latter it is generally open, it can only be practised by deceit and fraud; and when the habit has obtained such a dominance that the customary restraints are thrown aside, there is a more complete abandonment of self-respect. In either sex, it is the physical craving produced by the continued action of the stimulant upon the nutrition of the nervous system which renders the condition of the habitual drunkard one with which it is peculiarly difficult to deal by purely moral means. Vain is it to recall the motives for a better course of conduct, to one who is already familiar with them all, but is destitute of the will to act upon them; the seclusion of such persons from the reach of alcoholic liquors, for a sufficient length of time to free the blood from its contamination, to restore the healthful nutrition of the brain, and to enable the recovered mental vigor to be wisely directed, seems to afford the only prospect of reformation; and this cannot be expected to be permanent, unless the patient determinately adopts and steadily acts on the resolution to abstain entirely from that which, if again indulged in, will be poison alike to his body and to his mind, and will transmit its pernicious influence to his offspring.—CARPENTER *Mental Physiology*, ch. 17, p. 652. (A., 1900.)

1732. INTEMPERANCE, MORTALITY RESULTING FROM—*Effects of the Use of Alcohol in Switzerland.*—In the cities of Switzerland every ninth man dies, directly or indirectly, of the consequences of drunkenness. What objection can be made against these statistics? No one dares assert that they are the production of bias. Our physicians are not temperance fanatics. At most, one might object that the causal relations are not demonstrated in all cases, that many of the patients would have died even without alcohol, perhaps only a little later. I do not deny that. But what cannot be denied is the fact of drunkenness. The physicians cannot report drunkenness as the only, or the contributing, cause of death if the patient has not been given to drunkenness. It is therefore a fact that every ninth man in the cities of Switzerland becomes a drunkard.—VON BUNGE *Der Kampf gegen die Trinksitten* (an address). (Translated for *Scientific Side-Lights.)*

1733. INTERCHANGE OF LAND AND SEA—*Cities Where Ocean Once Rolled.*—Imperfect as is our information of the

changes which they [deltas] have undergone within the last three thousand years, they are sufficient to show how constant an interchange of sea and land is taking place on the face of our globe. In the Mediterranean alone, many flourishing inland towns, and a still greater number of ports, now stand where the sea rolled its waves since the era of the early civilization of Europe. If we could compare with equal accuracy the ancient and actual state of all the islands and continents, we should probably discover that millions of our race are now supported by lands situated where deep seas prevailed in earlier ages. In many districts not yet occupied by man, land animals and forests now abound where ships once sailed; and, on the other hand, we shall find, on inquiry, that inroads of the ocean have been no less considerable.—LYELL *Geology*, ch. 18, p. 289. (A., 1854.)

1734. ——— ——— *Coal-beds Buried under Ocean-rocks.*—All of the formations of the Secondary and Tertiary periods are on top of the coal—and this shows that after the age of rank vegetable growth there was a sinking of the earth in many places far down into the ocean—so that vast layers of rock formed on top of these beds of vegetable matter. In England great chalk-beds crop out in cliffs on the southern coast, and, as we have seen, these chalk-rocks are largely made up of the shells of marine animals. London stands on a chalk-bed from six hundred to eight hundred feet thick. Indeed, England has been poetically called Albion, White-land, from this appearance of her coast. All of the great chalk-beds were formed ages after the coal-beds, as the latter are found in the upper strata of the Paleozoic period.—ELISHA GRAY *Nature's Miracles*, vol. i, ch. 3, p. 26. (F. H. & H., 1900.)

1735. INTEREST, ACQUIRED, BECOMES CONTROLLING—An adult man's interests are almost every one of them intensely artificial: they have slowly been built up. The objects of professional interest are most of them, in their original nature, repulsive; but by their connection with such natively exciting objects as one's personal fortune, one's social responsibilities, and especially by the force of inveterate habit, they grow to be the only things for which in middle life a man profoundly cares. —JAMES *Talks to Teachers*, ch. 10, p. 98. (H. H. & Co., 1900.)

1736. INTEREST IN THE DIVINE RECORD—To me it seems that to look on the first land that was ever lifted above the waste of waters, to follow the shore where the earliest animals and plants were created when the thought of God first expressed itself in organic forms, to hold in one's hand a bit of stone from an old sea-beach, hardened into rock thousands of centuries ago, and studded with the beings that once crept upon its surface or were stranded there by some retreating wave, is even of deeper interest to men than the relics of their own race, for these things tell more directly of the thoughts and creative acts of God.—AGASSIZ *Geological Sketches*, ser. i, ch. 2, p. 29. (H. M. & Co., 1896.)

1737. INTEREST OF MAN IN ANIMALS — *Pigeons Carefully Bred by Ancient Egyptians—A Pastime of Nobles and Kings.* —The art of and fancy for pigeon-breeding is very ancient. Even more than 3,000 years before Christ it was carried on by the Egyptians. The Romans, under the emperors, laid out enormous sums upon the breeding of pigeons, and kept accurate pedigrees of their descent, just as the Arabs keep genealogical pedigrees of their horses, and the Mecklenburg aristocracy of their own ancestors. In Asia, too, among the wealthy princes, pigeon-breeding was a very ancient fancy; in 1600, the court of Akber Khan possessed more than 20,000 pigeons. Thus in the course of several centuries, and in consequence of the various methods of breeding practised in the different parts of the world, there has arisen out of one single originally tamed form an immense number of different races and varieties, which in their most divergent forms are extremely different from one another, and are often curiously characterized.—HAECKEL *History of Creation*, vol. i, ch. 6, p. 144. (K. P. & Co., 1899.)

1738. INTERPRETATION INSTINCTIVE—*The Less Known Explained by the Better Known—The Concave Seen in Relief.*—Now, it may be asked, why should we tend to transform the concave into the convex rather than the convex into the concave? . . . We are rendered much more familiar, both by Nature and by art, with raised *(cameo)* design than with depressed design *(intaglio)*, and we instinctively interpret the less familiar form by the more familiar. . . . [An] illustration of this kind of illusion recently occurred in my own experience. Nearly opposite to my window came a narrow space between two detached houses. This was, of course, darker than the front of the houses, and the receding parallel lines of the bricks appeared to cross this narrow vertical shaft obliquely. I could never look at this without seeing it as a convex column, round which the parallel lines wound obliquely. Others saw it as I did, tho not always with the same overpowering effect. I can only account for this illusion by help of the general tendency of the eye to solidify impressions drawn from the flat, together with the effect of special types of experience, more particularly the perception of cylindrical forms in trees, columns, etc.—SULLY *Illusions*, ch. 5, p. 85. (A., 1897.)

1739. INTERVENTION OF NATURAL CAUSES—*Not the Negation of Divine Power.*—The reluctance to admit, as belonging to the domain of Nature, any special

exertion of divine power for special purposes, stands really in very close relationship to the converse notion, that where the operation of natural causes can be clearly traced, there the exertion of divine power and will is rendered less certain and less convincing. This is the idea which lies at the root of Gibbon's famous chapters on the spread of Christianity. He labors to prove that it was due to natural causes. In proving this, he evidently thinks he is disposing of the notion that Christianity spread by divine power, whereas he only succeeds in pointing out some of the means which were employed to effect a divine purpose.—ARGYLL *Reign of Law*, ch. 1. p. 12. (Burt.)

1740. INTOLERANCE OF INFIDELITY—*Voltaire Denied Existence of Fossils—Mingled Ignorance and Inconsistency.*—Voltaire had used the modern discoveries in physics as one of the numerous weapons of attack and ridicule directed by him against the Scriptures. He found that the most popular systems of geology were accommodated to the sacred writings, and that much ingenuity had been employed to make every fact coincide exactly with the Mosaic account of the creation and deluge. It was, therefore, with no friendly feelings that he contemplated the cultivators of geology in general, regarding the science as one which had been successfully enlisted by theologians as an ally in their cause. He knew that the majority of those who were aware of the abundance of fossil shells in the interior of continents were still persuaded that they were proofs of the universal deluge; and as the readiest way of shaking this article of faith, he endeavored to inculcate skepticism as to the real nature of such shells, and to recall from contempt the exploded dogma of the sixteenth century, that they were sports of Nature. He also pretended that vegetable impressions were not those of real plants. Yet he was perfectly convinced that the shells had really belonged to living *Testacea*, as may be seen in his essay "On the Formation of Mountains." He would sometimes, in defiance of all consistency, shift his ground when addressing the vulgar, and, admitting the true nature of the shells collected in the Alps and other places, pretend that they were Eastern species, which had fallen from the hats of pilgrims coming from Syria. The numerous essays written by him on geological subjects were all calculated to strengthen prejudices, partly because he was ignorant of the real state of the science, and partly from his bad faith. On the other hand, they who knew that his attacks were directed by a desire to invalidate Scripture, and who were unacquainted with the true merits of the question, might well deem the old diluvian hypothesis incontrovertible, if Voltaire could adduce no better argument against it than to deny the true nature of organic remains.—LYELL *Principles of Geology*, bk i, ch. 4, p. 54. (A., 1854.)

1741. INTOLERANCE OF PAGANISM—*Science under Ban—Underestimate Denounced as Exaggeration—Persecution of Anaxagoras.*—The astronomers of the school of Pythagoras, who thought they gave a grand idea of the day star by estimating its distance at 72,000 kilometers (44,740 miles), and its diameter at 618 kilometers (384 miles), were as far from the reality as an ant who believed itself the size of a horse. And yet to estimate the sun as of the size of the Peloponnesus was then such boldness in the eyes of the classical conservatives and the teaching doctors that for having asserted this beginning of truth the philosopher Anaxagoras was outrageously persecuted and condemned to death—a sentence commuted to a decree of exile, on the petition of Pericles! The trial of Galileo was, later on, a repetition of that of Anaxagoras.—FLAMMARION *Popular Astronomy*, bk. iii, ch. 3, p. 244. (A.)

1742. INTOLERANCE OF THE SCHOOLMEN—*Discoveries in Anatomy and Physiology Met by Persecution.*—The more rigid the system, the fewer and the more thorough were the methods to which the healing art was restricted. The more the schools were driven into a corner by the increase in actual knowledge, the more did they depend upon the ancient authorities, and the more intolerant were they against innovation. The great reformer of anatomy, Vesalius, was cited before the theological faculty of Salamanca; Servetus was burned at Geneva along with his book, in which he described the circulation of the lungs; and the Paris faculty prohibited the teaching of Harvey's doctrine of the circulation of the blood in its lecture-rooms.—HELMHOLTZ *Popular Lectures*, lect. 5, p. 210. (L. G. & Co., 1898.)

1743. INTOLERANCE, PARALYZING EFFECT OF—*Abdication of Galileo—Science under Ban of Church.*—"Having held and believed that the sun is the center of the universe and immovable, and that the earth is not the center of the same and that it does move, . . . I abjure with a sincere heart and unfeigned faith, I curse and detest the said errors and heresies and generally all and every error and sect contrary to the Holy Catholic Church," wrote Galileo Galilei, in mortal terror of the Inquisition; that was in 1633. Twenty years before, under the protection of the Grand Duke of Tuscany, he had asserted the heliocentric doctrine, with no worse result than a friendly admonition from Cardinal Bellarmine, and he had agreed not to promulgate it further. But, as the world grew wiser, it smiled at the theological claims to infallibility in matters of physics, and at last, in 1620, the church itself yielded sufficiently to sanction the discussion of the Copernican theory as an hypothesis merely. This gave Galileo a safe opportunity, as he believed, once more publicly to reaffirm his belief therein. He went too far, and tried

to prove it orthodox. However the ecclesiastical authorities may have intended to deal with others, the fact of his having violated, as they claimed, his earlier promise gave them a reason for coming upon him despite the permissory decree. He was the most shining of all shining marks. To crush him would do more to paralyze independent philosophical thought, at least within the pale of the church, than any random anathema that Rome could hurl.

The effect upon all Europe was profound. The faithful, who found themselves in the van of philosophical progress, stopped and drew back. The blight of uncertainty fell upon them. If, after years of free discussion, Copernicanism had come to be heresy, inviting the dread visit of the Holy Office, what then might be safely taught and studied?—PARK BENJAMIN *Intellectual Rise of Electricity*, ch. 12, p. 355. (J. W., 1898.)

1744. ——— ——— *Buffon Recants His "Theory of the Earth."*—Soon after the publication of his "Natural History," in which was included his "Theory of the Earth," [Buffon] received an official letter (January, 1751) from the Sorbonne, or Faculty of Theology in Paris, informing him that fourteen propositions in his works "were reprehensible and contrary to the creed of the church." The first of these obnoxious passages, and the only one relating to geology, was as follows: "The waters of the sea have produced the mountains and valleys of the land—the waters of the heavens, reducing all to a level, will at last deliver the whole land over to the sea, and the sea successively prevailing over the land will leave dry new continents like those which we inhabit." Buffon was invited by the college, in very courteous terms, to send in an explanation, or rather a recantation of his unorthodox opinions. To this he submitted, and a general assembly of the faculty having approved of his "Declaration," he was required to publish it in his next work. The document begins with these words: "I declare that I had no intention to contradict the text of Scripture; that I believe most firmly all therein related about the creation, both as to order of time and matter of fact; and I abandon everything in my book respecting the foundation of the earth, and generally all which may be contrary to the narration of Moses."—LYELL *Principles of Geology*, bk. i, ch. 3, p. 39. (A., 1854.)

1745. INTOXICATION ONE WITH INSANITY—*Difference Only in Duration—Poison Gradually Eliminated from the Blood.*—The states of mind temporarily produced by intoxicating agents—alcohol, opium, hashish, and the like—are closely akin to one another in this fundamental character, as they are also to the delirium of fevers or other diseases, which is due to the introduction of a morbid matter into the blood, whereby a zymosis or fermentation of its own materials is produced which gives it a poisonous action on the brain. In the second case, as in the first, the effect is transient, the poison being gradually eliminated from the circulation by the excretory apparatus (including the respiratory organs), so that the blood regains its original purity. And it is this temporary character alone which differentiates the mental perversion of intoxication and delirium from that which is persistent in insanity.—CARPENTER *Mental Physiology*, bk. ii, ch. 17, p. 637. (A., 1900.)

1746. ——— ——— *Monomania—Sea Captain Shooting Sailors to Suppress Imaginary Mutiny—Small Portion of Stimulant Harmful—Heredity.*—The closeness of the affinity between the states of insanity and alcoholic intoxication is further made apparent by the extreme readiness with which the balance of reason is disturbed by a small quantity of liquor in those unfortunate individuals in whom there exists a predisposition to mental derangement. The power of volitional control being already feeble it is easily overthrown; and the propensities or passions which are always unduly excitable are readily aroused into morbid activity by this provocation, so that a very few glasses of wine or a small quantity of spirits are sufficient to induce what may be regarded either as a fit of drunkenness or a paroxysm of insanity—the two influences concurring to produce the mental disturbance which neither of them would have alone sufficed to bring about. Not unfrequently the state thus induced is one of temporary monomania, the mind becoming possessed by a particular emotional state which governs the conduct and leads to the perpetration of atrocious crimes. Thus at least two instances of this kind have occurred within the recollection of the writer in which the captain of a ship, having been thus seized with the belief that his crew was in a state of mutiny, has killed one of them after another in (as he believed) rightful self-defense. Such a predisposition may arise from previous injury or disease affecting the brain (tropical sunstroke being often alleged as the cause of it), or it may be inherited; and it exists in peculiar force in those who have an hereditary tendency to insanity derived from drunkenness on the part of the parents. Cases are continually occurring in which drunken outrages are committed by individuals thus circumstanced, in whose excuse it is alleged that a very small quantity of liquor is sufficient to inflame their passions and destroy their self-control. —CARPENTER *Mental Physiology*, ch. 17, p. 651. (A., 1900.)

1747. INTROSPECTION A MARVELOUS POWER—*Evidence of Mental Growth.*—There is nothing more wonderful in the constitution of our minds than the power we have of standing aside, as it were, for a time from the ordinary channel of our own thoughts and of looking back upon their cur-

rents coming down from the hills of memory and association to join their issues in our present life. But this sort of looking in upon ourselves and treating ourselves as a subject of natural history is to all men a difficult and to most men an impossible operation. They have neither time for it nor thought for it. The conscious energies of the will are so near us and so ever present with us that they shut out our view of the forces which lie behind. Yet there are some facts common in the experience of all men which may help us to a conception of the truth. One of these is the fact of mind growing with the growth of years—a fact determined by the recollection of childhood, of youth, and of maturity. By comparing ouselves with ourselves at former periods of life—by the memory of feelings and of opinions, and of methods of thought which we have outgrown and left behind us, we can detect the action of forces which have told upon our minds—traces, in short, of the laws to which they have been subject. Some of these laws have been nothing more than laws of physical growth—the conceptions of the mind undergoing a development consequent on the growth of our material organism.—ARGYLL *Reign of Law*, ch. 6, p. 171. (Burt.)

1748. INTUITIONS NOT EXPLAINED BY EXPERIENCE OF INDIVIDUAL OR OF RACE—*The Ancient Explanation (Job xxxii, 8).*—It is a familiar truth that some propositions are necessary. We must attach the predicate "equal" to the subject "opposite sides of a parallelogram" if we think those terms together at all, whereas we need not in any such way attach the predicate "rainy," for example, to the subject "tomorrow." The dubious sort of coupling of terms is universally admitted to be due to "experience"; the certain sort is ascribed to the "organic structure" of the mind. This structure is in turn supposed by the so-called apriorists to be of transcendental origin, or at any rate not to be explicable by experience; whilst by evolutionary empiricists it is supposed to be also due to experience, only not to the experience of the individual, but to that of his ancestors as far back as one may please to go. . . . Taking the word "experience" as it is universally understood, the experience of the race can no more account for our necessary or a priori judgments than the experience of the individual can.—JAMES *Psychology*, vol. ii, ch. 28, p. 617. (H. H. & Co., 1899.)

1749. INUNDATION POSSIBLE—*Subsidence of Land Might Empty Lake Superior.*—If we restrict ourselves to combinations of causes at present known it would seem that the two principal sources of extraordinary inundations are, first, the escape of the waters of a large lake raised far above the sea; and, secondly, the pouring down of a marine current into lands depressed below the mean level of the ocean.

As an example of the first of these cases we may take Lake Superior, which is more than 400 geographical miles in length and about 150 in breadth, having an average depth of from 500 to 900 feet. The surface of this vast body of fresh water is no less than 600 feet above the level of the ocean; the lowest part of the barrier which separates the lake on its southwest side from those streams which flow into the head waters of the Mississippi being about 600 feet high. If, therefore, a series of subsidences should lower any part of this barrier 600 feet, any subsequent rending or depression, even of a few yards at a time, would allow the sudden escape of vast floods of water into a hydrographical basin of enormous extent. If the event happened in the dry season, when the ordinary channels of the Mississippi and its tributaries are in a great degree empty, the inundation might not be considerable; but if in the flood season, a region capable of supporting a population of many millions might be suddenly submerged.—LYELL *Principles of Geology*, bk. i, ch. 10, p. 156. (A., 1854.)

1750. INVENTION AMONG SAVAGES—*Devices for Deluding Game—Origin of the "Stalking-horse."*—The Australian hunter takes the wallaby (a small kangaroo) by fastening to a long rod like a fishing-rod a hawk's skin and feathers, making the sham bird hover with its proper cry till it drives the game into a bush where it can be speared. Of devices of stalking with an imitated animal one of the most perfect is that of the Dogrib Indians, when a pair of hunters go after reindeer; the foremost carries a reindeer's head, while in the other hand he has a bunch of twigs against which he makes the head rub its horns in a lifelike way, and the two men, walking as the deer's fore and hind legs, get among the herd and bring down the finest. In England, till of late years, fowlers used to hide behind a wooden horse moved along on wheels, and a relic of this survives in the phrase "to make a stalking-horse of one," often now used by people who have no idea what the word meant.—TYLOR *Anthropology*, ch. 9, p. 209. (A., 1899.)

1751. ——— ——— *Possibilities of New Implement Exhausted — Mechanical Progress.*—I find that in the employment of the curved knife the Eskimo, the Canadian tribes, together with their kindred on the northern boundary of the United States, and, more than all, the North Pacific tribes on both sides of the ocean have exhausted the possibilities of an implement that has been in the hands of some only a century or two. The arts of all these tribes were bettered and not degraded by the curved knife. In every case they were immensely improved. The form of knife with straight, short blade made it possible for the northern and western tribes to become better carvers and engravers. Before the possession

of iron there is meager evidence that either of these areas possessed other than the most trivial carvings in hard material. Their best results were in soft wood and slate, by means of beaver-tooth or shark's-tooth knives. The curved knife serves to confirm the opinion that as soon as any process or device came within the scope of a people's intelligence they have mastered it and brought it to a climax, from which time on new ideas and new inventions replaced the old.—MASON *The Man's Knife among the North American Indians (Report of U. S. National Museum for 1897*, p. 742).
